RP338

INDEX

DEPT. OF APPLIED CHEMISTRY
CAL. UNIV. LIBRARY

ALDERS, Dr. L. E. : Production of Maternal-type Plants through Crosses to Apomictic Species, 101
Aarkrog, A. : Variation in the Ratio of Strontium-89 to Strontium-90 in Precipitation Samples with Sampling Height, 771
Aarsen, P. N., and Kemp, A. : Rapid Spectrophotometric Micromethod for Determination of Histaminase Activity, 1195
Abdo, M. S., *et al.* : Thyroid Function of Friesian Cows during the Œstrous Cycle and in Conditions of Ovarian Abnormality, 693
Abdoh, Dr. Y., and Pirelahi, H. : Alkaloid Content of Tobacco Seeds, 791
Abnormal Hæmoglobin in Sheep (Dr. M. Braend, G. Efremov and O. Helle), 700
Abnormal Transport of Vitamin B_{12} in Plasma in Chronic Myelogenous Leukæmia (Dr. C. A. Hall and A. E. Finkler), 1207
Aborigines : Abnormal Hæmoglobin and Glucose-6-phosphate Dehydrogenase Deficiency in Malayan (Dr. L. I. L. Eng and J. Chin), 291
Abortion : *Syncephalastrum* associated with Bovine Mycotic (Dr. P. D. Turner), 399
Abraham, Dr. E. P. : Antimicrobial Agents and Chemotherapy—1963, *review*, 960
Abraham, Prof. E. P., and Sabath, Dr. L. D. : Synergistic Action of Pencillins and Cephalosporins against *Pseudomonas pyocyanea*, 1066
Absence of Kynurenine in Hair of Patients with Scleroderma (Dr. F. Levit), 593
Absence of Late Replication of a Human X-Ring Chromosome (Dr. R. A. Pfeiffer and Dr. T. Büchner), 804
Absorber : Generation of Giant Pulses from a Neodymium Laser by a Reversibly Bleachable (B. H. Soffer and Dr. R. H. Hoskins), 276
Absorption of Radio Waves in the Galaxy (Prof. G. R. A. Ellis and P. A. Hamilton), 272
Absorption Spectra of Silver Vapour (Prof. C. Shin-Piaw and W. Loong-Seng), 276
Absorptive Cells of the Jejunum : Possible Explosions in (A. Mohiuddin, H. L. Chan and K. F. Yap), 1214
Acanthodes : A Reinterpretation of the Visceral Skeleton of (Dr. R. S. Miles), 457
Acetate : Molecular Structure of π-allyl-palladium (Dr. M. R. Churchill and Prof. R. Mason), 777
Acetobacter acetigenum in a Lactate-buffered Glycerol Medium : Pigment Formation by (Prof. K. Ramamurti and C. P. Jackson), 402
Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin : Rapid induction by (Dr. H. O. J. Collier, A. R. Hammond, S. Horwood-Barrett and C. Schneider), 1316
Acetylcholine by some Esters of Trimethoxybenzoic Acid : Inhibition of Synthesis of (Dr. S. P. Bhatnagar, A. Lam and J. D. McColl), 485
Acetylcholine Content of the Caudate Nucleus : Effect of Locally Applied Hemicholinium on the (C. O. Hebb *et al.*), 1309
Achromotricia in Iron-deficient Rats (R. P. Cusack and Dr. W. D. Brown), 582
α-Acid Glycoprotein produced in Certain Pathological States : Sialic Acid-deficient (K. Schmid *et al.*), 75
Acoustic Similarity in Short-term Memory : Semantic and (A. D. Baddeley), 1116
Acridine Orange : Inhibition of Protein Synthesis by (Dr. A. V. Zelenin and Mrs. E. A. Liapunova), 45
Acridine Orange under Streaming Conditions : Optical Rotatory Power of DNA and of its Complex with (Dr. S. F. Mason and Dr. A. J. McCaffery), 468
Acridine Orange with Nucleic Acid in Intact Living Human Organs : Intravital Fluorescence Microscopy in the Qualitative Evaluation of the Interaction of (Dr. M. Sherif), 390
Act of Creation (A. Koestler), *review* by Dr. E. H. Hutten, 975
Actinometer for Ultra-violet Radiation : A Sensitive Chemical (H. Moroson and A. Gregoriades), 676
Actinomycin C on Immune Responses *in vivo* : Effect of (I. N. Brown), 487
Actinomycin D. : Inhibition of Interferon Biosynthesis by (Prof. R. R. Wagner), 49
Resistance of Synthesis of Influenza Virus Ribonucleic Acid to the Action of (Dr. A. G. Bukrinskaya), 205
Active Transport of Alkaline Earth Ions as Physiological Base of the Accumulation of some Radionuclides in Freshwater Molluscs (O. van der Borght and S. van Puymbroeck), 533
Acton, Dr. L. W. : Inverse Compton Effect as a Possible Cause of the X-Ray Radiation of Solar Flares, 64
Adams, Dr. G. E., *et al.* : Pulsed Radiolysis of *Cyclo*hexane Solutions : Evidence for Reactions of Electrons, 1187
Adenine Nucleotide from Nerve Axons : Release of (Prof. A. S. Kuperman, W. A. Volpert and M. Okamoto), 1000
Adenosine-triphosphatase and Potassium Retention in X-irradiated Erythrocytes (D. K. Myers and L. Levy), 1324
Adenosine Triphosphate : Prevention of Fatty Liver by Administration of (Dr. D. E. Hyams and Prof. K. J. Isselbacher), 1196
Adgie, R. L. : Comparison of Radio and Optical Positions of some Identified Radio Sources, 1028
Adipose Tissue : Effect of Serum from Normal and Diabetic Subjects on Incorporation of Glucose 1-Carbon-14 into Individual Fatty Acids of Rat (Prof. A. R. Hennes *et al.*), 943
Adler, Dr. M., and Gutman, Prof. A. B. : 3-Methylxanthosine, 681
ADP-induced Platelet Aggregation by Substituted Amino-Acids : Inhibition of (Dr. E. W. Salzman and Dr. D. A. Chambers), 698
Adrenal Medulla : Various Cell Types of the (I. Benedeczky *et al.*), 591
Adrenal Medulla of Rats Exposed to Cold : Marked Decrease of DNA in the Nuclei of the (M. Viola), 1094
Adrenal and Plasma Corticosteroids and Ascorbic Acid Content during Bone Fracture Healing (A. H. Said), 386
Adrenaline in Mice : Effect of Methylamphetamine on the Psychomotor Depression produced by (Prof. E. Fischer *et al.*), 695
Adsorption of Krypton and Xenon on Evaporated Metal Films (Z. Knor and V. Ponec), 466
Advances in Carbohydrate Chemistry, Vol. 18 (edited by M. L. Wolfrom and R. S. Tipson), *review* by Prof. W. J. Whelan, 412
Advances in Chemotherapy, Vol. 1 (edited by A. Goldin and F. Hawking), *review* by Prof. F. Bergel, 960
Advances in Food Research, Vol. 12 (edited by C. O. Chichester and E. M. Mrak), *review* by Dr. A. M. Copping, 218
Advances in Inorganic Chemistry and Radiochemistry, Vol. 5 (edited by H. J Emeléus and A. G. Sharpe), *review* by Dr. D. W. A. Sharp, 418
Advances in Organometallic Chemistry, Vol. 1 (edited by F. G. A. Stone and R West), *review* by G. Wilkinson, 1127
Advances in Space Science and Technology, Vol. 5 (edited by Frederick I Ordway. III), *review* by D. G. King-Hele, 111
Aerosols : The Mechanics of (N. A. Fuchs), *review* by J. F. Croft, 1236
Afro-American : Simultaneous Occurrence of Hæmoglobins C and Lepore in an (Dr. H. M. Ranney and A. S. Jacobs), 163
After Pesticides—What? (R. H. Wright), 121
Agar-diffusion Technique for estimating Gibberellin Production by Plant Organs (R. L. Jones and Dr. I. D. J. Phillips), 497
Age : Changes in the Human A Antigen of Erythrocytes with the Individual's (Dr. F. J. Grundbacher), 192
Age of Caledonian Orogeny and Metamorphism in Britain (Dr. T. G. Miller). 358 : (F. J. Fitch, Dr. J. A. Miller and Dr. P. E. Brown), 358
Age-related Changes in Short-term Memory : Influence of Motivation, Perception and Attention on (J. Inglis), 103
Ageing : Environmental Stress and Biological (J. M. Ordy *et al.*), 724
Aggregation of Ice Crystals in Strong Electric Fields (Dr. J. Latham and C P. R Saunders), 1293
Agricultural Atlas of England and Wales (Dr. J. T. Coppock), *review* by J. L Beveridge, 958
Agricultural Research Council Food Research Institute, Norwich Director appointed, 1036
Agricultural Research Institute, Ghana, Technical Report No. 62, 829
Agriculture : Poisonous Substances used in, 1256
Ahnström, G., *et al.* : Tritium Labelling of Antibodies, 796
Aiken, Prof. H., and Main, W. F. (edited by) : Switching Theory in Space Technology, *review* by G. J. Herring, 1127
Air : Saturation Characteristics of a Spherical Ionization Chamber and a Determination of Boag's Constant for (Dr. T. E. Burling and S. R. Husain), 670
Aircraft Industry, 1255
Air Pollutant : Sulphur Dioxide as an, 1257
Alarm Substances and Alarm Behaviour in Social Hymenoptera (Dr. U. W. Maschwitz), 324
Albedo : Polarization and (C. R. Nagaraja Rao), 277
Albu, A. : Automation and the Future of Man, *review*, 3
Albumin, Serum, in the Presence of Congo Red : Paper Electrophoresis of Heat-treated (Prof. S. Tekman and Dr. N. Öner), 287
Alchohol Dehydrogenase in *Drosoppila melanogaster* : Genetic Variation of (F. M. Johnson and C. Denniston), 906
Alchehols to *Salmonella typhimurium LT2* : Relationship between Chemical Structure and the Extent of Protection against Ionizing Radiation given by (A. B. Sidle), 597
Aldehyde Groups in Histochemistry : Formazan Reaction as a Confirmatory Test for (Dr. P. J. Stoward and Dr. L. Master), 488
Aldehydes : Ferrocene-containing Polymers : Polycondensation of Ferrocene with (E. W. Neuse), 179
Aldolase in Several Experimental Atrophies : Increase of Muscle Permeability to (C. Pellegrino and C. Bibbiani), 483
Algal Cultures with Caffeine : Purification of (S. W. Bowne, jun.), 801
Alginic Acid from a *Pseudomonas* Micro-organism : Polysaccharide resembling (Dr. A. Linker and Dr. R. S. Jones), 187
Alimarin, I. P., and Petrikova, M. N. : Inorganic Ultramicroanalysis, *review* by Dr. D. T. Lewis, 514
Alkali Positive Ions : Ionization of Mercury by (Prof. R. M. Chaudhri *et al.*), 987
Alkaline Earth Ions as Physiological Base of the Accumulation of some Radionuclides in Freshwater Molluscs : Active Transport of (O. van der Borght and S. van Puymbroeck), 533
Alkaline 'Pernitrite' : Formation and Decomposition of (Dr. H M. Papee and Dr. G. L. Petriconi), 142
Alkaline Phosphatase : Sub-cellular Localization of Rat Kidney (Dr. M. J. Griffin and Dr. R. P. Cox), 476
Alkaline Phosphatase Activity of the Leucocytes in Animals (Dr. L-I. L. Eng), 191
Alkaline Phosphatase in the Malpighian Tubules of the Desert Locust : Distribution of (B. Nickerson), 499
Alkaloid Content of Tobacco Seed (Dr. Y. Abdoh and H. Pirelahi), 791
Allan, D., et *al.* : Techniques for the Measurement *in vitro* of Tissue Sensitization in Immunized Pigs, 895
Allan, T. D., *et al.* : Magnetic, Gravity and Depth Surveys in the Mediterranean and Red Sea, 1245
Allen, B. T., and Vanneste, W. : Chlorine Hyperfine Splittings in Phenoxy Free Radicals, 991
Allen, J. R. L. : Pre-Pickwell Down Age of the Plateau Beds (Upper Devonian) in South Wales, 364
Allen, jun., Dr. T. C., and McWhorter, Prof. F. P.: Transfer of Lily Curl Stripe by a Leaf Union Method Applicable to Monocotyledonous Plants, 604
Allgemeine Cytologie (Prof. E. Grundmann), *review* by Prof. P. C. Koller, 956
Allium cepa : Aminothioamides as Protectors against the Effect of Gamma-rays in (Dr. M. D. El Khalifa), 708
Allogeneic Tissue : *In vitro* Cytotoxic Effect of Lymphoid Cells from Mice Immunized with (Dr. T. Vainio *et al.*), 453
Allotypes : Rabbit γ-globulin (U. Grodecka) 595
Allotypes of Hen Serum Proteins (Dr. D. Skalba), 894
Allsop, Dr. H. L. : Rubidium/Strontium Ages from the Western Transvaal. 361
π-allyl-palladium Acetate : Molecular Structure of (Dr. M. R. Churchill and Prof. R. Mason), 777
AlOCl Solutions : Aluminium Oxyfluoride and the Polymerized Species in (Dr. B. Siegel and Dr. R. L. Johnson), 375

Alonso, W. : Location and Land Use, *review* by Prof. D. Walker, 1128
Apsen, Prof. E. L., and Cranmore, D. : Chromosomes of the Domestic Cat, 99
Alpha-amylase Activity of Varieties of English Wheat (B. A. Stewart), 1088
Alpha-frequency of Electroencephalogram and a Stabilized Retinal Image (C. R. Evans and Dr. G. K. Smith), 303
Alter, Dr. D., et *al.* : Pictorial Astronomy, *review* by Patrick Moore, 1019
Altitude : Brain Maturation Measured by Electroshock Seizures in Rats at High (Prof. L. M. Heim and Prof. P. S. Timiras), 1157
Altman, Prof. J., and Das, G. D. : Autoradiographic Examination of the Effects of Enriched Environment on the Rate of Glial Multiplication in the Adult Rat Brain, 1161
Alumina : Rapid Reaction of Lime with Hydrous (Dr. S. Diamond), 183
Aluminium *K* Diagram and Non-diagram Lines : Influence of Chemical Combination on (W. L. Baun and D. W. Fischer), 642
Aluminium Oxyfluoride and the Polymerized Species in AlOCl Solutions (Dr. B. Siegel and Dr. R. L. Johnson), 375
Alveolar Lining Film of the Lungs : Structure of the (Prof. J. Groniowski and Mrs. W. Biczyskowa), 745
Alveolar Surfactant, Lung Elasticity and Lung Stability : Lung (Dr. R. M. Mendenhall and A. L. Mendenhall, jun.), 747
Ambrose, Dr. E. J., and Langley, O. K. : Isolation of a Mucopeptide from the Surface of Ehrlich Ascites Tumour Cells, 53
American Association for the Advancement of Science, 131st meeting, 630
American Subminiature Electronic Component Parts Data Annual, 1963-64 (edited by G. W. A. Dummer and J. Mackenzie Robertson), *review* by Prof. J. Greig, 218
Amines as Components of Toasted Oat Flakes : Volatile (Dr. J. Hrdlička and G. Janíček), 1201
Amines, Sympathomimetic, by Thyroxine : Exaltation of Toxicity of (Prof. B. N. Halpern et *al.*), 387
Amino-acid Composition of Prekeratin (Prof. A. G. Matoltsy), 380
Amino-acid Levels on Protein Synthesis *in vitro* : Influence of (Dr. B. M. Hanking and Prof. S. Roberts), 1194
D-Amino-acid Oxidase : New Mould (Dr. I. Chibata et *al.*), 684
Amino-acids : Chemical Analysis of Proteins Low in Aromatic (Dr. R. M. Howell et *al.*), 1088
Inhibition of ADP-induced Platelet Aggregation by Substituted (Dr. E. W. Salzman and Dr. D. A. Chambers), 698
Amino-acids from Three Tissues of *Cancer antennarius* : A Comparison of Free and Bound (Dr. R. D. Schafer), 1193
2-β-Aminoethylisothiourea, Glutathione and Serotonin of Mice against Whole-body Irradiation : Protection with (Dr. J. R. Maisin), 196
Beta-Amino-isobutryic Acid and Taurine in Mongolism : Urinary Excretion of (Prof. H. O. Goodman et *al.*), 650
Aminothioamides as Protectors against the Effect of Gamma-rays in *Allium cepa* (Dr. M. D. El Khalifa), 708
3-Amino-1,2,4-triazole : Reversal by Histidine of the Inhibition of *Prototheca* Growth due to (Dr. P. J. Casselton), 93
Amitosis on the Distribution of Human Lactic Acid Dehydrogenase Isozymes : Effect of (Dr. E. D. Wachsmuth), 681
Ammocœte Larva of the Lamprey, *Lampetra fluviatilis* : Ultrastructure of the Sensory Hair-cells in the Labyrinth of the (Prof. O. Lowenstein and M. P. Osborne), 197
Amorphous Magnetic Films (Dr. C. W. B. Grigson, D. B. Dove and G. R. Stilwell) 173
Amphetamine in Man : Rhythmic Urinary Excretion of (Dr. A. H. Beckett and M. Rowland), 1203
Amphetamine on Spinal Reflexes : Effect of (L. Vyklický and V. Tabin), 384
Amphibia : Physiology of the (edited by J. A. Moore), *review* by Dr. C. L. Smith 1022
Amphibia and Reptilia in Mainland Britain : Introduced Species of, 1146
Amphibian Blood *in vitro* : Erythrocytes and the Liquefying of Clotted (Dr. E. Hachett and C. Hann), 590
Amphibian Metamorphosis : Thalidomide and Induced (Dr. J. R. Tata), 939
Amprino, R. and Bonetti, D. A. : Effect of the Implantation Site on the Development of Grafted Limb Bud Mesoderm in Chick Embryos, 298
Amyema, *Amylotheca*, and *Scurrula* on Synthetic Media : Growth of Embryos of (Dr. B. M. Johri and Dr. Y. P. Singh Bajaj), 1220
Amylase : Isozymes of Salivary (Prof. J. Muus and J. M. Vnenchak), 283
Amylotheca, and *Scurrula* on Synthetic Media : Growth of Embryos of *Amyema*, Dr. B. M. Johri and Dr. Y. P. Singh Bajaj), 1220
Amyotrophic Lateral Sclerosis, Attempts to Demonstrate a Transmissible Agent in Kuru, and other Sub-acute and Chronic Nervous System Degenerations of Man (Dr. D. C. Gajdusek and Dr. C. J. Gibbs, jun.), 257
Anæsthetics by Carbon Dioxide : Potentiation of the Nerve-Depressant Effect of Local (Prof. G. A. Condouris and A. Shakalis), 57
Analogy : Paralogy, a Concept Complementary to Homology and (I. J. Hunter), 604
Analytical Chemistry (edited by Carl E. Crouthamel), Vol. 3, Parts 4-7, *review* by A. A. Smales, 8
Analytical Chemistry of Niobium and Tantalum (R. W. Moshier), *review* by Prof. J. R. Partington, 511
Analytical Chemistry of Ruthenium (T. D. Avtokratova), *review* by Prof. J. R. Partington, 511
Analytical Chemistry of Thorium (D. I. Yabchikov and E. K. Gol'braikh), *review* by Prof. J. R. Partington, 511
Anaxagoras and the Birth of Physics (D. E. Gershenson and D. A. Greenberg). *review* by Mrs. M. B. Hall, 968
Anaxagoras and the Birth of Scientific Method (D. E. Gershenson and D. A. Greenberg), *review* by Mrs. M. B. Hall, 968
Ancillary Mathematics (Sir Harry Massey and H. Kestelman), second edition, *review* by Prof. T. A. A. Broadbent, 979
Andersen, P., and Rudjord, T. : Simulation of a Neuronal Network operating Rhythmically through Recurrent Inhibition, 289
Anderson, Dr. A. B. : Human Tumours Secreting Catecholamines, *review*, 613
Anderson, Dr. C. A., and Wood, Dr. G. F. : Wool Scouring, 1259
Anderson, Dr. E. C., et *al.* : Detection of an Interstellar Flux of Gamma-rays, 766
Anderson, J. C., et *al.* : The Antral Hormone Gastrin, 931
Anderson, Dr. M. R. : Variations in the Rate of Induction of Chemical Carcinogenesis according to Differing Psychological States in Rats, 55
Anderson, Dr. T. B. : Kink-bands and Related Geological Structures, 772
Andrewes, Sir Christopher : The Background to Chemotherapy of Virus Diseases, *review*, 959
Viruses of Vertebrates, *review* by Dr. F. K. Sanders, 216
Andriese, P. C., et *al.* : Catalase Activity of a Crude Enzyme Preparation from Iron-chlorotic Barley (*Hordeum vulgaris*) Seedlings, 1198
Androgen-induced Reversal of Parental Behaviour in the Female Rabbit (Dr. H. J. Campbell), 809
Angino, Prof. E. E. : Far Infra-red Spectra of Montmorillonite, Kaolinite and Illite, 569
Angiotensinase : Electrophoretic Behaviour of Serum (Dr. D. Klaus and Dr. P. Biron), 381
Animal Cells : Effect of Calcium on Intracellular Sodium and Potassium Concentrations in Plant and (Prof. G. A. Morrill et *al.*), 641
Animal Reproduction and Artificial Insemination, Report of the Fifth International Congress, 829
Animal Worlds (Marston Bates), *review* by Dr. L. Harrison Matthews (203, 907), *corrigendum*, 333
Animals : Variability of the Strontium-90 and Cæsium-137 Burden of Native Plants and (L. L. Eberhardt), 238
Vertical Distribution of Radionuclides as Measured in Oceanic (Prof. W. G. Pearcy and C. L. Osterberg), 440
Anisotropy Field of Continuous Magnetic Films subjected to Inhomogeneous Dri Fields : Apparent (Dr. P. I. Bonyhard), 1185 ; (J. G. Edwards), 1185
Annals and Magazine of Natural History, 6 No. 71, 525
Annealing Behaviour of Recoil Cobalt-57 Atoms in Hexammine Nickel Chloride (K. Yoshihara), 1296
Annett, Mrs. M. : Model of the Inheritance by Handedness and Cerebral Dominance, 59
Annual Rings in Big Sagebrush, *Artemisia tridentata* (C. W. Ferguson), *review* by Dr. C. R. Metcalfe, 514
Annual Species of Medicago (C. C. Heyn), *review* by R. D. Meikle, 316
Anopheles atroparvus with Different Behavioural Responses to Contacts with DDT : Selection of Some Strains of (J. L. Gerold and J. J. Laarman), 500
Anoxic Bacteria to X-rays by Di-t-butyl Nitroxide and Analogues : Sensitization of (Dr. P. T. Emmerson and Dr. P. Howard-Flanders), 1005
Antagonism by Aspirin : Rapid Induction by Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective (Dr. H. O. J. Collier et *al.*), 1316
Antarctic Expedition, Soviet : Information Bulletin, Vols. 1 and 2, *review* by Dr. G. de Q. Robin, 110
Antarctic Peninsula : New U.S. Research Station in the (Prof. T. O. Jones), 825
Antarctic Seas : Biology of the (edited by M. O. Lee), *review* by Dr. J. W. S. Marr, 1239
Antarctic Snows : Strontium-90 and Cæsium-137 in (R. N. Woodward), 1291
Anthers of *Datura* : *In vitro* Production of Embryos from (S. Guha and S. C. Maheshwari), 497
Anthropological Observations of Blood Groups in Hiroshima (T. Tsuchiya, M. Kurata, A. Fukuma, T. Onishi, Dr. M. Yokoyama, H. Kobayashi and K. Tomita), 87
Antibiotic-producing Microscopic Fungi (V. I. Bilai), *review* by Dr. R. W. G. Dennis, 8
Antibiotics on Serum- and Liver-cholesterol Concentrations in Chicks : Influence of Basic (P. De Somer, H. Vanderhaeghe and Dr. H. Eyssen), 1305
Antibiotics Small Proteins : Are Peptide (Dr. M. Bodanszky and Dr. D. Perlman), 840
Antibodies : Tritium Labelling of (C. G. Rosén et *al.*), 796
Antibodies against Tumour-specific Antigens in Methylcholanthrene-induced Mouse Sarcomas : Effect on Tumour Growth in Syngeneic Recipients of (G. Möller), 846
Antibodies in Animals Immune to Helminth Parasites : Reagin-like (Dr. B. M. Ogilvie), 91
Antibodies to Viruses of the Columbia *SK* Group in Sciuridae in Britain (Dr. A. D. Vizoso and R. Hay), 56
Antibody : Chemical Aspects of Inhibitors of Rho(D) (Prof. M. C. Dodd et *al.*), 549
Antibody : Cell-bound and Cell-binding, in the Peripheral Blood of Immunized Rabbits (Dr. E. Sorkin), 794
Antibody, Neutralizing, Responses of Guinea-Pigs to Inactivated Rubella Virus Vaccine (Dr. J. W. Frankel), 655
Antibody Production by Leucocytes in Peripheral Blood (Dr. M. Landy, R. P. Sanderson, M. T. Bernstein and Dr. A. L. Jackson), 1320
Antibody Response in Mice immunized with Transplantable Tumours : Type of (D. E. H. Tee, J. Watkins, M. Wang, and D. B. Gammack), 391
Antigen Barrier of the Mouse Placenta (Dr. D. R. S. Kirby, Dr. W. D. Billington, Dr. S. Bradbury and Dr. D. J. Goldstein), 548
Antigen, Changes in the Human A, of Erythrocytes with the Individual's Age (Dr. F. J. Grundbacher), 192
Antigen Xg^a in Gibbons : Blood Group (J. Gavin et *al.*), 1322
Antigenic Properties of Human Tumours (D. E. H. Tee, M. Wang and J. Watkins). 897
Antigenicity of Trypanosome Nuclei : Evidence that DNA is not coupled to Histone in these Protozoa (Dr. J. S. Beck and Dr. P. J. Walker), 194
Antigens, Immunochromatographic Partition of Soluble, on Columns of Insoluble Diazo-gamma-Globulins (Dr. S. DeCarvalho et *al.*), 265
Antimicrobial Agents : A New Class of (Prof. L. B. Kier, Prof. M. C. Dodd, P. Sapko and T. G. Stewart), 697
Antimicrobial Agents and Chemotherapy—1963 (edited by J. C. Sylvester), *review* by Dr. E. P. Abraham, 960
Antiviral Activity of Gliotoxin and Gliotoxin Acetate (Dr. W. A. Rightsel, H. G. Schneider, B. J. Sloan, P. R. Graf, F. A. Miller, Q. R. Bartz, J. Ehrlich and G. J. Dixon), 1333
Antiviral Agent, A New : 4-Bromo-3-methylisothiazole-5-carboxaldehyde thiosemicarbazone, M and B 7714 (Dr. R. Slack, Dr. K. R. H. Wooldridge, Dr. J. A. McFadzean and S. Squires), 587
Antral Hormone Gastrin (Dr. H. Gregory, Dr. P. M. Hardy, D. S. Jones, Prof. G. W. Kenner and Dr. R. C. Sheppard), 931 ; (J. C. Anderson, M. A. Barton, Prof. R. A. Gregory, Dr. P. M. Hardy, Prof. G. W. Kenner, J. K. MacLeod, J. Preston, Dr. R. C. Sheppard and J. S. Morley), 931 : (H. J. Tracy and Prof. R. A. Gregory), 931
Apomictic Species : Production of Maternal-type Plants through Crosses to (Dr. L. E. Aalders), 101
Aposymbiotic Cockroaches by means of Lysozyme : Production of (H. Malke), 1223
Apples : Occurrence of Farnesene in the Natural Coating of (Dr. K. E. Murray et *al.*), 80
Preliminary Investigation of the Influence of Controlled Atmosphere Storage on the Organic Acids of (D. A. Kollas), 758
Apples of the Variety 'Bramley's Seedling' by *Nectria galligena*, Bres : Rotting of (Dr. T. R. Swinburne), 493
Applications of Microfilm Readers in Petrography (H. B. Milner), 1262
Aqueous Biological Tissue Samples in an Electron Spin Resonance Spectrometer : Use of Long Cavities for (M. Kent and Dr. J. R. Mallard), 396
Aqueous Solution : Phosphate-mediated Dehydrogenation of Alchohol in the Photochemistry of Ferrocyanide in (Mrs. M. Snirom and Prof. G. Stein), 778
Aqueous Solution by Atomic Hydrogen : Inactivation of Chymotrypsin in (Dr. L. K. Mee et *al.*), 1056
Aqueous Systems : Rotational Structure in the Chemiluminescence Spectrum of Molecular Oxygen in (Dr. A. U. Khan and Prof. M. Kasha), 241
Aqueous Systems at 77°K : Reversible Photochemical Bleaching in Frozen (P. N. Moorthy and Prof. J. J. Weiss), 776
Aqueous and other Solutions : Photochemistry and Radiation Chemistry of Fluorobenzene in (Dr. I. Loeff et *al.*), 1300
Arachis hypogaea : Auxin and Gibberellin-like Substances in Peanut (A. Gordin-Sharir and Prof. P. F. Wareing), 1308
Archæology in Northern Rhodesia and Turkey, 230

Archæology of Cape Denbigh, The (Prof. J. L. Giddings), *review* by M. C. Burkitt, 1125
Archbold, S. and Hughes, T. P. : Electron Temperature in a Laser-heated Plasma, 670
Archdeacon, Prof. J. W., et *al.* : Progesterone and 6-Chloro-Δ^6-17-Acetoxy-progesterone as Inhibitors of Spermatogenesis in the Rabbit, 261
Simple Separation of Rabbit Marrow Myeloid Cells from Erythroid Cells, 996
Architecture of the Germplasm (Prof. V. Grant), *review* by Dr. H. L. K. Whitehouse, 978
Architecture, Technology and South Kensington (Sir William Holford), 616
Are Peptide Antibiotics Small Proteins? (Dr. M. Bodanszky and Dr. D. Perlman), 840
Arndt, P. R., and Soicher, H. : Downward Electron Flux at 1,000 km Altitude from Electron Content Measurement at Mid-latitudes, 983
Arginine-rich Histone during Spermiogenesis in *Drosophila melanogaster* : Autoradiographic Evidence of Synthesis of an (Dr. C. C. Das et *al.*), 1038
Argles, M. : South Kensington to Robbins, *review* by Dr. W. L. Sumner, 310
Argon at Ultra-high Vacuum : A Simple Mass Spectrometer for the Analysis of (E. Farrar et *al.*), 531
Arid and Semi-Arid Lands : Soil Fertility Problem in (Dr. F. Pauli), 1286
Armstrong, E. A. : A Study of Bird Song, *review* by Prof. J. A. Mulligan, 1239
Armstrong, W. : Oxygen Diffusion form the Roots of Some British Bog Plants, 801
Arnold, Prof. J. R., et *al.* : Detection of an Interstellar Flux of Gamma-rays, 766
Arnold, P., and Moray, Dr. N. : Confirmation of Apparent Genetic Assimilation of Behaviour in *Drosphila melanogaster*, 504
Arousal and Childhood Autism (C. Hutt, S. J. Hutt, D. Lee and Dr. C. Ounsted), 908
Arrau, J., et *al.* : Luteinizing Hormone-like Activity in Human Median Eminence Extracts, 584
Arthrobotrys conoides : Carbon dioxide dependent Morphogenesis in (S. Bartnicki-Garci et *al.*), 804
Arvan, Dr. D. A., et *al.* : Sedimentation Rate of Cells in Metaphase as compared with Cells in Interphase, 1225
Arya, Dr. S. C. : Growth of Bovine Parainfluenza-3 Virus in Chick Tissues growing on Polythene, 807
Asahina, E., and Tanno, K. : A Large Amount of Trehalose in a Frost-resistant Insect, 1222
Ascension Island 1964 : Oxford Expedition to (F. B. Atkins et *al.*), 722
Ascites Tumour Cells during Freezing and Thawing : Unusual Action of Heparin on (Prof. J. K. Sherman), 100
Ascobolus immersus : 'Selfers' and High Mutation Rate during Meiosis in (A. Paszewski and S. Surzycki), 809
Ascoli-Bartoli, U., et *al.* : Forward Scattering of Light from a Laboratory Plasma. 672
Ascorbic Acid Content during Bone Fracture Healing : Adrenal and Plasma Corticosteroids and (A. H. Said), 386
Ascorbic Acid in Tendon Fibres : Histotopochemistry of (Dr. F. Bartoš), 1104
Ascorbic Acid and Photoreduction of its Oxidized Forms : Influence of Red and Far-red Light on the Photo-oxidation of (Dr. L. W. Mapson and Dr. T. Swain), 886
Asen, S., et *al.* : Ethylene Oxide an Antagonist of Ethylene in Metabolism, 756
Aslib : Papers presented at the thirty-eighth annual conference, 428
Substance of Lord Shackleton's presidental address, 1025
Asparagopsis in Europe (Dr. P. S. Dixon), 902
Aspects of Soil Science (E. M. Bridges), 432
Aspirin : Rapid Induction by Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by (Dr. H. O. J. Collier et *al.*), 1316
Assay of Gonadotrpohins by the Deciduoma Method (N. Kovačič), 385
Assynt Dykes : Isotopic Ages of (Dr. C. R. Evans and Dr. J. Tarney), 638
Astronomy : The Flammarion Book of, *review* by Patrick Moore, 815
Astronomy Center : A New Joint American-Australian (Prof. T. Gold and Prof. H. Messel), 18
Astronomy with Binoculars (J. Muirden), *review* by Patrick Moore, 1019
Atkins, F. B., et *al.* : Oxford Expedition to Ascension Island 1964, 722
Atmosphere System : A Gas-tight Growth Chamber for Investigating Gaseous Nitrogen Changes in the Soil : Plant : (P. J. Ross et *al.*), 444
Atmospheric Properties and the Apparent Solar Diameter : 26-Month Oscillation in (Prof. R. E. Newell), 278
Atomic Collisions : Physics of (Dr. J. B. Hasted), *review* by Prof. H. Edels, 980
Atomic Energy Community : The European, seventh annual report, 833
Atomic Hydrogen : Inactivation of Chymotrypsin in Aqueous Solution by (Dr. L. K. Mee et *al.*), 1056
Atomic Oxygen-Acetylene Reaction : Negative Ion Formation in the (Dr. W. J. Miller and Dr. A. Fontijn), 679
Atomic Sulphur : Forbidden Lines from (Dr. J. W. McConkey et *al.*), 1180
Atrophies : Increase of Muscle Permeability to Aldolase in Several Experimental (C. Pellegrino and C. Bibbiani), 483
Attenuating Blast waves produced by an Instantaneous Release of Thermal Energy (J. Wadsworth), 673
Audus, Prof. L. J. : Chemistry of Plant Processes, *review*, 213
Audus, Prof. L. J., and Yeomans, L. M. : Auxin Transport in Roots, 559
Aurelia aurita : Light as an Inhibitor of Strobilation in (D. R. N. Custance), 1219
Aurora : Rocket Optical Observation of a Day-time (S. M. Silverman et *al.*), 461
Auroral-zone X-rays : Long-period Pulsations of (Prof. H. Trefall and S. L. Ullaland), 1148
Austenite/Carbon Reaction in Cast Iron (R. A. Cresswell), 465
Australia : Development of Northern, 26
Australian Journal of Science, **27**, 924
Australian and New Zealand Association for the Advancement of Science thirty-seventh annual congress, 26
Austwick, K. (edited by) : Teaching Machines and Programming, *review* by J. A. Leonard, 219
Autism : Arousal and Childhood (C. Hutt et *al.*), 908
Auto-immunity : Diagnosis of (M. N. Rashad et *al.*), 393
Automation and the Future of Man (S. Demczynski), *review* by A. Albu, 3
Autoradiographic Evidence of Synthesis of an Arginine-rich Histone during Spermiogenesis in *Drosophila melanogaster* (Dr. C. C. Das, Prof. B. P. Kaufmann and Prof. H. Gay), 1008
Autoradiographic Examination of the Effects of Enriched Environment on the Rate of Glial Multiplication in the Adult Rat Brain (Prof. J. Altman and G. D. Das), 1161
Autoradiography of Hæmolysin-producing Cells : Microslide Method permitting (Dr. H. K. Berglund), 89
Autoxidation of Carbanions in Azoxybenzene (Dr. T. J. Wallace, J. E. Hofmann and H. Pobiner), 376
Auxiliary Electrodes in Mosaic Membrane Systems : Porosity Mosaics (Prof. C. W. Carr and Prof. K. Sollner), 878
Auxin Activity of Certain Oximes (Dr. C. H. Fawcett), 1200
Auxin Transport in Roots (L. M. Yeomans and Prof. L. J. Audus), 559 ; (P. E. Pilet), 559
Auxin and Gibberellin-like Substances in Peanut (*Arachis hypogaea*), (A. Gordin-Sharir and Prof. P. F. Wareing), 1308
Avena sativa : Metabolic Fate of some Chlorinated Phenoxyacetic Acids in the Stem Tissue of (E. W. Thomas et *al.*), 286
Avian Visual System : Organization within the Central and Centrifugal Fibre Pathways in the (J. I. McGill), 395
Avian and Mammalian Hæmoglobins of Different Ages : Chemical Reactivity of (Dr. H. Walter and F. W. Selby), 1209
Avtokratova, T. D. : Analytical Chemistry of Ruthenium, *review* by Prof. J. R. Partington, 511
Awai, Dr. K., et *al.* : Effect of Serum from Normal and Diabetic Subjects on Incorporation of Glucose 1-Carbon-14 into Individual Fatty Acids of Rat Adipose Tissue. 943
Axelrod, Dr. J., et *al.* : Demonstration of Hydroxyindole-O-methyl Transferase, Melatonin, and Serotonin in a Metastatic Parenchymatous Pinealoma, 1323
Axelrod, Dr. J., and Glowinski, Dr. J. : Inhibition of Uptake of Tritiated-noradrenaline in the Intact Rat Brain by Imipramine and Structurally Related Compounds, 1318
Axial Organ and Fluid Circulation in Echinoids (Prof. N. Millot and Dr. H. G. Vevers), 1216
Axons : Potassium-free Effect in Squid (Dr. A. S. Frumento and Dr. L. J. Mullins). 1312
Axons of the Crab *Carcinus maenas* : Distribution of Phthalocyanine Dye (Heliogen Blue SBL) in Ultrastructures of Vital Dyed (Ja. Ju. Komissarchik and S. V. Levin), 203
Aykroyd, Dr. W. R. : Proceedings of the Sixth International Congress of Nutrition, *review*, 961
Ayres, Prof. J. C., and Paton, Dr. A. M. : Use of a Fluorescent Brightener for tracing the Passage of *Salmonella* in Eggs, 803
Azelaic Acid Degradation by *Pseudomonas* sp. : Pimelic Acid as a By-product of (L. Janota-Bassalik and Prof. L. D. Wright), 501
Azoxybenzene : Autoxidation of Carbanions in (Dr. T. J. Wallace et *al.*), 376

BABAN, N., et *al.* : Specific Elastolysate Test, 473
Babesiosis : Strain Immunity in (Dr. L. L. Callow), 1213
Bacillus megaterium : Molecular Sieving by Cell Membranes of (Dr. R. Schorrer and Prof. P. Gerhardt), 649
Bacillus subtilis Chromosome during Spore Germination : Synchronous and Dichotomous Replications of the (M. Oishi et *al.*), 1069
Back, M. H., and Laidler, Prof. K. J. : Kinetics of Pyrolytic Reactions, 1143
Background to Chemotherapy of Virus Diseases (Prof. C. H. Stuart-Harris and Dr. L. Dickinson), *review* by Sir Christopher Andrewes, 959
Bacteria : Fatty Acid Composition of Lipids extracted from Three Spherical (Dr. J. P. Brown and Dr. B. J. Cosenza), 802
Mechanism of β-Ketoadipate Formation by (L. N. Ornston and Prof. R. Y. Stanier), 1279
Bacteria or Bacterial Endotoxin : Patterns of Interferon Appearance in Mice injected with (Prof. W. R. Stinebring and Prof. J. S. Youngner), 712
Bacteria and their Viruses : The Genetics of (Dr. W. Hayes), *review* by Dr. B. A. D. Stocker, 6
Bacterial Endotoxins : Proceedings of a Symposium, Rutgers University, 1963 (edited by M. Landy and W. Braun), *review* by Dr. R. H. Gorrill, 1020

Black Soap Films : Water Content of (W. K. Thompson and B. A. Pethica), 1085
Blastomyces (*Paracoccidioides*) *brasiliensis* in Africa (Dr. C. A. Salles), 1211
Blaxter, Dr. K. L. : Appointed Director of the Rowett Research Institute, 229
Bleeding in the Surgical Patient, 1140
Blennorrhœa (*LB4*) Strain of the Trachoma-inclusion Conjunctivitis Virus Group : Behaviour in Eggs and Tissue Culture of the Inclusion (Dr. N. M. Larin and J. D. Treharne), 166
Blister Blight in Soils Augmented with Nickel : Resistance of Tea Plants to (Dr. C. S. Venkata Ram), 1227
Blood Cells : Separation of White (Dr. A. Bøyum), 793
Blood Clotting : Ellipsometer Recordings of Changes in Optical Thickness of Adsorbed Films associated with Surface Activation of (Dr. L. Vroman and A. Lukosevicius), 701
Blood Culture Method for the Study of Bovine Chromosomes (P. K. Basrur and J. P. W. Gilman), 1335
Blood Group Antigen Xg^a in Gibbons (J. Gavin, J. Noades, Dr. P. Tippett, Dr. R. Sanger and Dr. R. R. Race), 1322
Blood Group Le^a Substance : Isolation of a Serologically Active, Fucose-containing, Trisaccharide from Human (V. P. Rege *et al.*), 740
Xg Blood Groups of Chinese (Prof. W. H. Boon, J. Noades, J. Gavin and Dr. R. R. Race), 1002
Blood Groups in Hiroshima : Anthropological Observation of (T. Tsuchiya *et al.*), 87
Blood *in vitro* : Erythrocytes and the Liquefying of Clotted Amphibian (Dr. E. Hatchett and C. Hann), 590
Blood or Rh_{null} : A Second Example of – – – / – – – (Dr. P. Levine, M. J. Celano, F. Falkowski, J. W. Chambers, Prof. O. B. Hunter, jun., and C. T. English), 892
Blood Plasma : Enzymes in (B. Hess), *review* by Dr. H. Lehmann, 215
Bloomfield, Dr. G. F., awarded the Colwyn Medal, 729
Blumberg, Dr. B. S., *et al.* : A New Variant of Transferrin from Greece, 382
Boag, Dr. J. W., *et al.* : Pulsed Radiolysis of *Cyclo*hexane Solutions : Evidence for Reactions of Electrons, 1187
Boag's Constant for Air : Saturation Characteristics of a Spherical Ionization Chamber and a Determination of (Dr. T. E. Burlin and S. R. Husain), 670
Bodanszky, Dr. M., and Perlman, Dr. D. : Are Peptide Antibiotics Small Proteins? 840
Body Surface Area in Human Beings (C. H. Van Graan and Prof. C. H. Wyndham), 998
Body Water : Changes in Psychological Performance associated with Changes in Total (R. J. Kerry and Dr. J. E. Orme), 1115
Boenig, H. V. : Unsaturated Polyesters, *review* by R. N. Lewis, 966
Boer, A. P., *et al.* : Fatty Acids of Beef Heart Sphingomyelin, 782
Bog Plants : Oxygen Diffusion from the Roots of Some British (W. Armstrong), 801
Bogoch, Dr. S., *et al.* : Separation of Cerebroproteins of Human Brain, 73
Bohr, Dr. H., and Deleu, Dr. J. : Uptake of Tetracycline by Human Bone *in vitro*, 1103
Bois, P. : Tumour of the Thymus in Magnesium-deficient Rats, 1316
Bokros, J. C., *et al.* : Influence of Structure on Mechanical Properties of Pyrolytic Carbon, 371
Boletin del Instituto Oceanografico, I, No. 2, 1961, 434
Boley, B. A., *et al.* (edited by) : High Temperature Structures and Materials : Proceedings of the Third Symposium on Naval Structural Mechanics, 1963, *review* by Prof. A. J. Kennedy, 414
Bolton, J. G., *et al.* : Distribution and Motions of OH near the Galactic Centre, 30
Boltyanskii, V. G., *et al.* : The Mathematical Theory of Optimal Processes, *review* by Dr. A. T. Fuller, 1124
Bombus : Occurrence of Microvilli and Micropinocytosis in Trophocyte of (C. R. Hopkins and Dr. P. E. King), 298
Bond, Dr. G. : Isotopic Investigations of Nitrogen Fixation in Non-legume Root Nodules, 600
Bonding of Hydrogen in Hydrogen-Montmorillonite (Prof. I. Th. Rosenqvist and P. Jørgensen), 176
Bone Fracture Healing : Adrenal and Plasma Corticosteroids and Ascorbic Acid Content during (A. H. Said), 386
Bone *in vitro* : Uptake of Tetracycline by Human (Dr. J. Deleu and Dr. H. Bohr), 1103
Bone *in vivo* : Effects of Electric Currents on (Prof. C. A. L. Bassett *et al.*), 652
Bone Marrow : Factors affecting the Expansion of the Stem Cell Pool in Transplanted Mouse (M. Bennett *et al.*), 351
Bone Marrow Cultures : Effects of Erythromycin and Tetracycline in Human (Dr. M. R. Vas *et al.*), 1100
Bone, Radium-226 in Diet and Human, from San Juan, Puerto Rico (N. A. Hallden and Dr. J. H. Harley), 240
Bonetti, D. A., and Amprino, R. : Effect of the Implantation Site on the Development of Grafted Limb Bud Mesoderm in Chick Embryos, 298
Bonnor, Prof. W. B. : Gravitational Collapse, 868
Boon, Prof. W. H., *et al.* : Xg Blood Groups of Chinese, 1002

Borgman, R. F. : Influence of Diet and Iodine-131 Injections on the Survival of Dystrophic Mice, 389
Boron Hydrides (Prof. W. N. Lipscombe), *review* by Prof. J. R. Partington, 511
Boron-Nitrogen Chemistry : An International Symposium, 1963, *review* by Prof. J. R. Partington, 511
Boron Toxicity in *Hevea brasiliensis* (Dr. V. M. Shorrocks), 599
Borst, Prof. L. B. : Molecular Excitations in Liquid Helium, 870
Bosch, M. C., *et al.* : Spaced-site Observations of Jupiter in 1963, 637
Bostick, F. X., *et al.* : Simultaneous Measurements and Spectral Analysis of Micropulsation Activity, 534
Botany : The Future of (Prof. R. D. Preston), 12
Botrytis cinerea Pers. : Influence of Fungicides on the Tomato and Growth of (C. L. Lockhart and F. R. Forsyth), 1107
Bourdillon, Mrs J. : The Sherpas of Nepal, *review*, 510
Bourke, Dr. P. M. Austin, *Obituary* of Dr. M. Doporto, 329
Bourne, Prof. G. H., and Kumamato, Dr. T. : Histochemical Evidence on the Localization of Succinic Dehydrogenase in the Synapse of the Central Nervous System of Rabbit, Rat and Guinea-pig, 295
Bovine Chromosomes : Blood Culture Method for the Study of (P. K. Basrur and J. P. W. Gilman), 1335
Bovine Cord : Isolation of a Highly Purified Encephalitogenic Protein from (Dr. R. F. Kibler *et al.*), 1273
Bovine Mycotic Abortion : *Syncephalastrum* associated with (Dr. P. D. Turner), 399
Bovine Parainfluenza-3 Virus in Chick Tissues growing on Polythene : Growth of (Dr. S. C. Arya), 807
Bower, Dr. B. F. : Site of Cardiac Glycoside Inhibition of Cation Transport, 786
Bowes, Dr. D. R., *et al.* : The Glasgow University Exploration Society Expedition to Mingulay, 25
Bowne, jun., S. W. : Purification of Algal Cultures with Caffeine, 801
'Boyle's Law' : Newton, Hooke, and (Prof. I. B. Cohen), 618
Boyum, Dr. A. : Separation of White Blood Cells, 793
Bracey, H. E. : Rural Life and Urbanized Society, *review*, 977
Brachet, Prof. J. : Effects of Histones on Embryonic Development, 1218
Brachet, Jean, and Mirsky, Alfred E. (edited by) : The Cell : Biochemistry, Physiology, Morphology, Vol. 6, *review* by Prof. J. M. Mitchison, 956
Bradbury, Dr. S., *et al.* : Antigen Barrier of the Mouse Placenta, 548
Bradfield, G. : Sonic Investigations on Internal Damping in Solids, 234
Bradford Institute of Technology : Appointments, 1140
Bradley, D. A. : Tidal Components in Hurricane Development, 136
Bradley, J. : Education and Environment, *review*, 976
Educational and Social Failure : Some Further Observations, 132
Bradykinin in the Development of Acute Pancreatitis : Role of (Dr. J. W. Ryan, J. G. Moffat and A. G. Thompson), 1212
Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin : Rapid Induction by Acetylcholine, (Dr. H. O. J. Collier *et al.*), 1316
Brænd, Dr. M., *et al.* : Abnormal Hæmoglobin in Sheep, 700
Bragg-Peak Lithium Ions on Normal Rabbit Skin, using Integral Dose as a Basis for Comparison : Relative Efficiency of High-LET Radiation (Dr. G. J. D'Angio *et al.*), 1267
Brain : Autoradiographic Examination of the Effects of Enriched Environment on the Rate of Glial Multiplication in the Adult Rat (Prof. J. Altman and G. D. Das), 1161
Distribution of Homovanillic Acid in the Human (Dr. H. Bernheimer), 587
Effect of Drugs on the Amount of Substance P in Rabbit (B. Radmanović), 1205
Separation of Cerebroproteins of Human (Dr. S. Bogoch *et al.*), 73
Brain Extracts : Ovarian Ascorbic Acid Depleting Activity in Human (M. de la Lastra and Prof. H. Croxatto), 583
Brain, Inhibition of Uptake of Tritiated-noradrenaline in the Intact Rat, by Imipramine and Structurally Related Compounds (Dr. J. Glowinski and Dr. J. Axelrod), 1318
Brain Maturation Measured by Electroshock Seizures in Rats at High Altitude (12,470 ft. : 3,800 m.) (Prof. L. M. Heim and Prof. P. S. Timiras), 1157
Brain, Mercury in Mouse, after Inhalation of Mercury Vapour and after Intravenous Injection of Mercury Salt (Dr. M. Berlin and L. G. Johansson), 85
Brain Tumours Induced in Hamsters inoculated intracerebrally at Birth with Rous Sarcoma Virus (G. F. Rabotti and W. A. Raine), 898
Braithwaite, E. R. : Solid Lubricants and Surfaces, *review* by K. H. R. Wright, 1128
Brambell, Prof. F. W. R., Awarded Royal Medal, 826, 1130

C-3 UNSUBSTITUTED Indoles : Reaction of Pyridoxal with (Dr. T. A. Scott), 77
Cabbage Looper, *Trichoplusia ni* (Hübner) : Methyl Linolenate as an Essential Nutrient for the (G. M. Chippendale, et *al.*), 710
Cænozoic Cores from the Pacific Ocean : Relationship of Palæomagnetic Reversals and Micropalæontology in Two Late (Dr. C. G. A. Harrison and Dr. B. M. Funnell), 566
Cæsium-137 Burden of Native Plants and Animals : Variability of the Strontium-90 and (L. L. Eberhardt), 238
Cæsium-137 in the Antarctic Snows : Strontium-90 and (R. N. Woodward), 1291
Cæsium-137 in Cougars feeding on Mule Deer : Trophic Level Effect on the Accumulation of (R. C. Pendleton et *al.*), 708
Cæsium-137 into Plants : Influence of Soil Organic Matter on the Entry of (Dr. D. A. Barber), 1326
Caffeine : Purification of Algal Cultures with (S. W. Bowne, jun.), 801
Caffeine Metabolism (D. J. Spedding and Prof. A. T. Wilson), 73
Cagan, Dr. R. H., and Karnovsky, Prof. M. L. : Enzymatic Basis of the Respiratory Stimulation during Phagocytosis, 255
Calcareous Sponges : Revision of the Classification of the (Dr. M. Burton), *review* by Dr. W. C. Jones, 416
Calcium on Intracellular Sodium and Potassium Concentrations in Plant and Animal Cells : Effect of (Prof. G. A. Morrill, Dr. H. R. Kaback and Dr. E. Robbins), 641
Calcium Sulphate Hemihydrate : Hydration of (M. J. Ridge), 70
Caledonian Arc System : A Possible Western Continuation of the Scandinavian (I. Hernes), 1186
Caledonian Orogeny : Some Radiometric Rock Ages and the Problem of the Southward Continuation of the East Greenland (Prof. L. R. Wager and Dr. E. I. Hamilton), 1079
Caledonian Orogeny and Metamophism in Britain : Age of (Dr. T. G. Miller), 358 ; (F. J. Fitch et *al.*), 358
Calligrapha philadelphica L. (Coleoptera : Chrysomelidae) : Effect of Supernumerary Chromosomes on Sex Ratio in (J. G. Robertson), 605
Callow, Dr. L. L. : Strain Immunity in Babesiosis, 1213
Calvin, Prof. M., awarded Ike Davy Medal, 728, 1130
Cambrian Dolomites of Skye : Grain Growth Fabrics in the (Dr. I. Karcz), 1080
Cambrian Succession of the St. Tudwal's Peninsula, South-west Caernarvonshire : Implication of Certain Sedimentary Structures within the (T. P. Crimes and P. G. Sly), 174
Camellia reticulata var. 'Capt. Rawes' : Root Formation on Cuttings of (M. Richards), 601
Campbell, Dr. H. J. : Androgen-induced Reversal of Parental Behaviour in the Female Rabbit, 809
Canberra Homopolar Generator : Tests with Solid Brushes on the (Dr. R. A. Marshall), 1079
Cancer : Familial Trends of, 734
Cancer antennarius : A Comparison of Free and Bound Amino-acids from Three Tissues of (Dr. R. D. Schafer), 1193
Cancer Research, 1036
Cancer Research, The International Support of, (Report of a Conference), 331
Cancers, Skin, induced by 20-Methylcholanthrene : Existence in the Thymus of a Factor protecting the Skin of the Mouse against the Induction of (Prof. J. Maisin), 1211
Candela, Prof. J. L. R., *et al.* (*corrigendum* **203**, 758), 1141
Canine Endotoxin Shock : Development of Shock-inducing Factor in (Prof. T. Fukuda et *al.*), 585
Cannon, Dr R. T., *et al.* : New Interpretation of the Geology of British Guiana, 115
Cantwell, Dr. T., *et al.* : Simultaneous Measurements and Spectral Analysis of Micropulsation Activity, 534
Canyon Diablo Meteoroid : Mass of the (Prof. C. Sharp Cook), 867
Canyon Diablo No. 2 and No. 3 Meteorites : Origin of the (Dr. D. Heymann), 819
Cape Denbigh : The Archæology of (Prof. J. L. Giddings), *review* by M. C. Burkitt, 1125
Capella and Convective Mixing in *F* and *G* Giants : Lithium in (Prof. G. Wallerstein), 367
Captan Analogues to Oat Powdery Mildew : Toxicity of (D. V. Richmond et *al.*), 1329
Carbanions in Azoxybenzene : Autoxidation of (Dr. T. J. Wallace et *al.*), 376
Carbohydrate Chemistry : Advances in, Vol. 18, (edited by M. L. Wolfrom and R. S. Tipson), *review* by Prof. W. J. Whelan, 412
Carbohydrate from Fibrin Monomer during Clotting : Release of (A. Rosenberg and R. H. Carman), 994
Carbon Dioxide : Potentiation of the Nerve-Depressant Effect of Local Anæsthetics by (Prof. G. A. Condouris and A. Shakalis), 57
Carbon Dioxide dependent Morphogenesis in *Arthrobotrys conoides* (S. Bartnicki-Garci, J. Eren and Prof. D. Pramer), 804
Carbon in Steels by the Measurement of the Prompt γ-Radiation emitted during Proton Bombardment : Determination of (T. B. Pierce, P. F. Peck and W. M. Henry), 571
Carbon-14 into Isolated Mitotic Apparatus during Early Development of Sea Urchin Eggs : Percentage Incorporation of Leucine labelled with (T. Bibring and G. H. Cousineau), 805
Carbon-14-labelled Acids, an Ester and Sodium Salt : Isotope Effects in the Infrared Spectra of some (B. H. Baxter and A. F. C. Horsler), 675
Carbon-14-labelled Tritolylphosphate with Glass Surfaces : Interaction of Phosphorus-32 and (Dr. M. E. Schrader and I. Lerner), 759
Carbonaceous Chondrite : 'Impact Contamination' of the Mokoia (Prof. G. Mueller), 567
Carbonium Ion Mechanism and Results of Solvolysis of (+)-2-Bromo-octane (Dr. W. Gerrard and Dr. H. R. Hudson), 876
Carbonyl Inductive (—*I*) Effect in Sterically Hindered Aromatic Ketones : Tetracyanoethylene Complexes as Indicators of the (C. Wilson et *al.*), 282
Carcinogenesis : Cell Differentation and the Primary Lesion in Mouse Mammary (Prof. E. Y. Lasfargues and Prof. M. R. Murray), 593
Carcinogenesis according to Differing Psychological States in Rats : Variations in the Rate of Induction of Chemical (Dr. M. R. Anderson), 55
Carcinogenesis by 4-Dimethylaminoazobenzene : Partial Protection by an Ox Liver Extract against Rat Liver (Dr. G. Fare), 1004
Carcinogenicity and Photodynamic Activity in Polycyclic Compounds : Charge-transfer Complex Formation, (Dr. S. S. Epstein et *al.*), 750
Carcinoma Cells Grown in Mice on a Meat Diet : Metabolism of Erhlich Ascites (J. Ilan and R. M. Johnstone), 1061
Cardiac Glycoside Inhibition of Cation Transport : Site of (Dr. B. F. Bower), 786
Cardiovascular Reactions to Noradrenaline : Effect of Rhinencephalic Lesions on (Dr. B. Minz and Dr. P. Noel), 82
Caribbean and Eastern Atlantic : Oceanography in the (Dr. T. J. Hart), 434
Carless, J. E., *et al.* (edited by) : Advances in Pharmaceutical Sciences, Vol. 1, *review* by Prof. E. Shotton, 1237
Carling, The Rock Carling Fellowship : Prof. W. V. Mayneord, 22
Carlsberg-Wellcome Travelling Research Fellowships, 24
Carlsen, E. N., et *al.* : Early Response of *Pinus thunbergii* to Acute γ-Irradiation, 394
Carman, R. H., and Rosenberg, A. : Release of Carbohydrate from Fibrin Monomer during Clotting, 994
Carnations : Effect of Damage and Fungal Infection on the Production of Ethylene by (W. H. Smith et *al.*), 92
Carr, Prof. C. W., and Sollner, Prof. K. : Auxiliary Electrodes in Mosaic Membrane Systems : Porosity Mosaics, 878
Carrison, L. C., et *al.* : High-pressure Polymorph of Zirconium Pyrophosphate, 573
Carrot Root Tissue Cultures : Sensitivity to Dinitrophenol of Potassium Absorption in (A. G. Smithers and Prof. J. F. Sutcliffe), 1330
Cartwright, B. and Brown, Dr. F. : Virus Specific Ribonucleic Acids in Baby Hamster Kidney Cells Infected with Foot-and-Mouth Disease Virus, 855
Cartwright, Dr. M. L., awarded the Sylvester Medal, 728, 1130
Case for Convection in the Moon (Dr. G. Fielder), 171
Caspian Sea and Siberian Rivers, 1139
Casselton, Dr. P. J. : Reversal by Histidine of the Inhibition of *Prototheca* Growth due to 3-Amino-1,2,4-triazole, 93
Castermans, A., et *al.* : Role of Debris of Tumour Ascitic Fluid in Transplantation Immuntiy, 704
Catalase Activity of a Crude Enzyme Preparation from Iron-chlorotic Barley (*Hordeum vulgaris*) Seedlings (S. Kotaka, Prof. A. P. Krueger and P. C. Andriese), 1198
Catalase Molecule seen by Electron Microscopy : Sub-units of the (Dr. R. C. Valentine), 1262
Catalysed Reaction of Xenon with Fluorine (Dr. B. G. Baker and Dr. P. G. Fox), 466
"Catalysis", symposium, 1258
Catecholamines : Human Tumours Secreting (Prof. H. Hermann and Prof R. Mornex), *review* by Dr. A. B. Anderson, 613
Caterpillar of *Leucinodes orbonalis* : Spinning Apparatus of the (R. C. Sinha), 904
Cation Transport : Site of Cardiac Glycoside Inhibition of (Dr. B. F. Bower), 786
Cationic Surfactants : Foam Fractionation of : Effect of Inorganic Acids and Bases (Prof. R. B. Grieves and D. Bhattacharyya), 441
Cats of the World (World Wildlife Series No. 1) (A. Denis), *review* by Dr. L. Harrison Matthews, 1023
Catsch, Prof. A. : Radioactive Metal Mobilization in Medicine, *review* by Dr. H. Spencer, 112
Caudate Nucleus : Effect of Locally Applied Hemicholinium on the Acetylcholine Content of the (C. O. Hebb et *al.*), 1309
Caughley, G., and Kean, R. I. : Sex Ratios in Marsupial Pouch Young, 491
Cave, Prof. A. J. E. : Cranial Epiphyses in Mammals, 838
Cavendish Laboratory in his Day : J. J. Thomson and the (Sir George Paget Thomson), *review* by Sir John Cockroft, 1235
Celano, M. J., et *al.* : A Second Example of ---/--- Blood or Rh$_{null}$, 892
Cell, The : Biochemistry, Physiology, Morphology, Vol. 6 (edited by Jean Brachet and Alfred E. Mirsky), *review* by Prof. J. M. Mitchison, 956
Cell-bound and Cell-binding Antibody in the Perpheral Blood of Immunized Rabbits (Dr. E. Sorkin), 794
Cell Membranes of *Bacillus megaterium* : Molecular Sieving by (Dr. R. Scherrer and Prof. P. Gerhardt), 649
Cell Numbers in Dried Leaf Material : Determination of (Dr. J. E. Dale), 904
Cell Protein Synthesis by an Established Mammalian Fibroblast Line : Collagen and (Prof. H. Green and Prof. B. Goldberg), 347
Cell Types, Various, of the Adrenal Medulla (I. Benedeczky, A. Puppi, A. Tigyi and Prof. K. Lissák), 591
Cells : Micro-slide Method permitting Autoradiography of Hæmolysin-producing (Dr. K. Berglund), 89
Cells in Metaphase as compared with Cells in Interphase : Sedimentation Rate of (Dr. D. A. Arvan et *al.*), 1225
Cells, Recovery from Sub-lethal X-ray Damage of Mammalian, during Inhibition of Synthesis of Deoxyribonucleic Acid (J. H. Kim et *al.*), 598
Cellulase from Pea Epicotyls (Prof. G. A. Maclachlan and J. Perrault), 81
Cellulose Acetate : A Continuous-flow Micro Double Diffusion Technique with (Mrs. C. M. Johnson et *al.*), 1321
Cellulose Derivatives for the Isolation of Biologically Active Molecules : New (H. H. Weetall and Dr. N. Weliky), 896
Cellulose Microfibrils : Fine Structure of Native (Dr. R. St. John Manley), 1155
Cement and Concrete Association *Catalogue of Publications*, 234
Report for the year 1963, 233
Training Courses in Concrete, 1965, 1038
Census Data : Estimating the Malthusian Parameter from (L. P. Lefkovitch), 810
Central Nervous System of Rabbit, Rat and Guinea-pig : Histochemical Evidence on Localization of Succinic Dehydrogenase in the Synapse of the (Dr. T. Kumamoto and Prof. G. H. Bourne), 295
Cephalosporins against *Pseudomonas pyocyanea* : Synergistic Action of Penicillins and (Dr. L. D. Sabath and Prof. E. P. Abraham), 1066
Ceramics, Special (S. N. Ruddlesden), 336
Cercariæ : *Schistosoma mansoni* : Humoral Transfer of Protective Factors produced by Irradiated (Dr. A. Perlowagora-Szumlewicz), 1009
Cerebellar Cortex : Golgi Cell Inhibition in the (Sir John Eccles et *al.*), 1265
Cerebellar Cortex, Discharge Patterns of Elements in Cat, and their Responses to Iontophoretically Applied Drugs (I. McCance and Dr. J. W. Phillips), 844
Cerebral Dominance : Model of the Inheritance by Handedness and (Mrs. M. Annett), 59
Cerebral Function in Infancy and Childhood (Prof. Albrecht Peiper), third revised German edition, *review* by Dr. T. T. S. Ingram, 413
Cerebral Œdema induced by Triethyltin in Rabbits by Cortico-steroids : Prevention of (Dr. J. M. Taylor, Dr. W. A. Levy, G. McCoy and Prof. L. Scheinberg), 891
Cerebroproteins of Human Brain : Separation of (Dr. S. Bogoch et *al.*), 73
Cerebrospinal Fluid in Human Beings : Movement of the (Dr. G. Di Chiro), 290
Cervigni, T., and Belli, M. L. : Treatment of Seeds with Ethylmethansulphate and Diethylsulphate, 1199
Cetrimide on the Intestinal Absorption of α-D-Glucosamine, L-Glucose and D-Xylose : First Receptor in Intestinal Sugar Transport : the Effect of Phloridzin and of (S. L. Hart and Dr. J. A. Nissim), 51
Chadwick, P. R. : Effect of Chemosterilants on *Glossina morsitans*, 299
Chalcogenides : Crystal Structure and Electrical Properties of some Cobalt-group (Dr. F. Hulliger), 644
Challenger Society and the Marine Laboratories (Development Commissioners' Scheme), joint meeting, 24
Chambers, Dr. D. A., and Salzman, Dr. E. W. : Inhibition of ADP-induced Platelet Aggregation by Substituted Amino-acids, 698

Chambers, J. W., et al.: A Second Example of – – – / – – – Blood or Rhnull, 892
Chan, H. L., et al.: Possible Explosions in Absorptive Cells of the Jejunum, 1214
Chandan, R. C., et al.: Lysozyme Content of Human Milk, 76
Chandraratna, Prof. M. F.: Genetics and Breeding of Rice, *review* by Dr. E. H. Roberts, 217
Changes in the Earth's Moment of Inertia (Prof. S. K. Runcorn), 823
Changes in the Human A Antigen of Erythrocytes with the Individuals Age (Dr. F. J. Grundbacher), 192
Chapman, Prof. S., awarded the Copley Medal, 728, 1129
Charge-transfer Complex Formation, Carcinogenicity and Photodynamic Activity in Polycyclic Compounds (Dr. S. S. Epstein, I. Bulon, J. Koplan, M. Small and N. Mantel), 750
Charlton, H. M.: Uptake of Labelled Precursors of Melatonin by the Epiphysis of *Xenopus laevis*, 1093
Charnock, H., et al.: Magnetic, Gravity and Depth Surveys in the Mediterranean and the Red Sea, 1245
Charter for Scientific Workers and Constitution of the World Federation of Scientific Workers, 233
Chatt, Prof. J.: Co-ordination Chemistry, 530
Chatterjee, Prof. S. D., and Banerji, P.: Radon Content of Rainwater, 1185
Chaudhri, M. M., et al.: Ionization of Mercury by Alkali Positive Ions, 987
Chaudhri, Prof. R. M., et al.: Ionization of Mercury by Alkali Positive Ions, 987
Cheeseman, Dr. G. C., and Jayne-Williams, D. J.: An Inhibitory Substance present in Milk, 688
Chelating Agents: Distribution of Cobalt-60 in the Rat as Influenced by (Dr. D. Khoung Lê), 696
Chelsea College of Science and Technology, *Prospectus* 1965-66, 1258
Chemical Analysis of Proteins Low in Aromatic Amino-acids (Dr. R. M. Howell, M. A. Cook and Dr. G. B. D. Scott), 1088
Chemical Aspects of Inhibitors of Rh$_o$(D) Antibody (Prof. M. C. Dodd, Dr. N. J. Bigley, G. A. Johnson and Prof. R. H. McCluer), 549
Chemical Combination on Aluminium *K* Diagram and Non-diagram Lines: Influence of (W. L. Baun and D. W. Fischer), 642
Chemical Institute of Canada: Awards in Chemical Engineering, 1141
Chemical Origin of Life, The (A. I. Oparin), *review* by Sir Cyril Hinshelwood, 949
Chemical Publication, Future of (Report of meeting), 331
Chemical Reactions in Shock Waves (E. F. Greene and J. P. Toennies), *review* by Dr. B. P. Levitt, 512
Chemical Reactivity of Avian and Mammalian Hæmoglobins of Different Ages (Dr. H. Walter and F. W. Selby), 1209
Chemical Structure and the Extent of Protection against Ionizing Radiation given by Alcohols to *Salmonella typhimurium LT2*: Relationship between (A. B. Sidle), 597
Chemicals in Soil by a Plough and a Rotavator: Lateral Drag of (L. N. Staniland), 503
Chemiluminescence Spectrum of Molecular Oxygen in Aqueous Systems: Rotation Structure in the (Dr. A. U. Khan and Prof. M. Kasha), 241
Chemiluminescent Reactions of SO with O and with O$_3$ (C. J. Halstead and Dr. B. A. Thrush), 992
Chemistry: A History of, Vol. 4 (Prof. J. R. Partington), *review* by Prof. A. R. Hall, 967
Chemistry of Cationic Polymerization, The (edited by P. H. Plesch), *review* by Dr. W. R. Moore, 963
Chemistry of Plant Processes (Prof. C. P. Whittingham), *review* by Prof. L. J. Audus), 213
Chemosterilants on *Glossina morsitans*: Effect of Two (P. R. Chadwick), 299
Chemotherapy: Advances in, Vol. I (edited by A. Goldin and F. Hawking), *review* by Prof. F. Bergel, 960
Chemotherapy—1963: Antimicrobial Agents and (edited by J. C. Sylvester), *review* by Dr. E. P. Abraham, 960
Chemotherapy of Virus Diseases: The Background to (Prof. C. H. Stuart-Harris and Dr. L. Dickinson), *review* by Sir Christopher Andrewes, 959
Chenoweth, Prof. M. B., et al.: Synthesis and Metabolism of Halothane-1-^{14}C, 471
Chernyakhovskaya, I. J., and Svet-Moldavsky, Dr. G. J.: Destruction of Homologous Cells in Tissue Culture by Nuclei of Immune Lymphocytes, 799
Chernyshev, E. A., et al.: Synthesis of Organosilicon Monomers, *review* by Dr. W. Gerrard, 512, 830
Chiasma Frequency and Gregarization in Locusts (Dr. D. J. Nolte), 1110
Chibata, Dr. I., et al.: New fluid D-Amino-acid Oxidase, 684
Chichester, C. O., and Mrak, E. M. (edited by): Advances in Food Research, Vol. 12, *review* by Dr. A. M. Copping, 218
Chick: Duration of Embryonic Hypersensitivity and its Relation to the Level of Differentiation of the (Prof. P. J. Van Alten), 797
Childhood Autism: Arousal and (C. Hutt et al.), 908
Chile: Image of, 914
Science and Development in (Hon. Dean Rusk), 915
Chimeras: Early Lymphatic Regeneration in Thymectomized Radiation (Dr. H. Balner and H. Dersjant), 941
Chimerism: Dizygotic Twins with XX/XY (Dr. I. A. Uchida et al.), 191
Chin, J., and Eng, Dr. L. I. L.: Abnormal Hæmoglobin and Glucose-6-phosphate Dehydrogenase Deficiency in Malayan Aborigines, 291
Chinese Water-balance Escapement, The (J. H. Combridge), 1175; (Prof. A. F. Burstall, W. E. Lansdale and P. Elliot), 1175; (J. H. Combridge), 1175
Chippendale, G. M., et al.: Methyl Linolenate as an Essential Nutrient for the Cabbage Looper, *Trichoplusia ni* (Hübner), 710
Chlorination of *Streptomyces aureofaciens*: Biochemical (Dr. M. Jarai et al.), 1307
Chlorine Hyperfine Splittings in Phenoxy Free Radicals (B. T. Allen and W. Vanneste), 991
6-Chloro-Δ^4-17-Acetoxyprogesterone as Inhibitors of Spermatogenesis in the Rabbit: Progesterone and (R. J. Ericsson et al.), 261
Chloroform Sensitivity of Mice (R. A. Bennet and A. Whigham), 1328
Chlorogenic Acid in Tumours of Interspecific *Nicotiana* Hybrids: Scopoletin, Scopolin and (Prof. T. C. Tso et al.), 779
p-Chloro-mercuribenzoate: Modified Phycoerythrin from *Porphyridium cruentum* treated with (E. Fujimori), 1091
Chlorophyll *b* in the Primary Reaction of Photosynthesis: Evidence for the Participation of (B. Rumberg), 860
Chlorophyll *in vivo* during the Greening Process: Geometrical Rearrangement of Aggregated (Dr. S. S. Brody), 470
Chloroplast Ribosomes (M. S. Odintsova, E. V. Golubeva and N. M. Sissakian), 1090
Cho, K. B., et al.: Metabolic Effects of Oxytocin in the Chicken, 385
Choanocytes in the Skin of *Harrimania kupfferi* (Enteropneusta), (Dr. A. Nørrevang), 398
Cholinesterase in Muscle: Electron-microscopical Localization of Products from Histochemical Reactions used to detect (Dr. R. Miledi), 293
Chopoorian, J. A., et al.: Photochromism of *p*-Phenylenediaminetetraacetic Acid absorbed in Porous Glass, 180
Chromatin: Sex Chromosomes and Sex (Dr. U. Mittwoch), 1032
Chromatium vinosum: Ubiquinone-40 and Vitamin K$_2$ (40) in (L. K. Osnitskaya et al.), 80
Chromatographic Heterogeneity of Pituitary Hormones: Possible Cause of Electrophoretic and (Dr. M. Sluyser), 574
Chromatographic Identification of Lysins in Normal Tissues and Tumours of Mice (E. Ponder and R. V. Ponder), 955
Chromatography in Geology (A. S. Ritchie), *review* by Prof. C. F. Davidson, 514
Chromatophore Fraction of *Rhodopseudomonas spheroides*: Structure of a (Dr. R. Langridge et al.), 97
Chromosome: Absence of Late Replication of a Human X-Ring (Dr. R. A. Pfeiffer and Dr. T. Büchner), 804
Xg^a Investigations of the Family of a Child with a Ring X (Dr. L. E. Nijenhuis and J. Gemser-Runia), 792
Chromosomes: Blood Culture Method for the Study of Bovine (P. K. Basrur and J. P. W. Gilman), 1335
A New Theory to Explain Crossing-over between Genes on (Prof. C. C. Lindegren), 322
Sequential and Reversible Inhibition of Synthesis of Ribonucleic Acid in the Nucleolus and: Effect of Benzamide and Substituted Benzimidazoles on Dipteran Salivary Glands (Dr. J. L. Sirlin and Dr. J. Jacob), 545
Chromosomes of X-ray-induced Giant Cells in Chinese Hamster *in vitro* (Dr. C. K. Yu), 1334
Chromosomes and Human Malformation (Dr. J. R. Ellis), 930
Chromosomes and Sex Chromatin: Sex (Dr. U. Mittwoch), 1032
Chromosomes of the Domestic Cat (D. Cranmore and Prof. E. L. Alpen), 99
Chromosomes of the Ring Seal (Dr. P. A. Corfman and Prof. R. M. Richart), 502
Chromosomes on Sex Ratios in *Calligrapha philadelphica L.* (Coleoptera: Chrysomelidae): Effect of Supernumerary (J. G. Robertson), 605
Church, B. W., et al.: Trophic Level Effect on the Accumulation of Cæsium-137 in Cougars feeding on Mule Deer, 708
Churchill, Dr. M. R., and Mason, Prof. R.: Molecular Structure of η-allyl-palladium Acetate, 777
Chymotrypsin in Aqueous Solution by Atomic Hydrogen: Inactivation of (Dr. L. K. Mee, Dr. G. Navon and Prof. G. Stein), 1056
Chymotrypsinogen Crystals: Nucleation and Morphology of (J. A. Hamilton et al.), 1085
CIBA Fellowships, 830
Cider: Determination of 2-Phenylethanol in (M. E. Kieser et al.), 887
Cigarette-smoke Condensates on Homografts of Neonatal Lung Tissue in Mice: Effect of (Dr. J. A. DiPaolo), 1159
Ciliary Body: Inhibition of Ouabain of Glycolysis in (Dr. M. V. Riley), 380
Civilization: The Role of Science in (R. B. Lindsay), *review* by Dr. S. Toulmin, 1127
Čížková, Prof. J., et al.: Influence of Serum of Children and Adolescents on the Growth of Plants, 1010
Clark, D. B., et al.: Upper Limit to Jupiter's X-ray Flux on September 30, 1962, 982

Coleman, Prof. R. M., and deSa, L. M.: Immunological Response to Implanted Adult Dwarf Tapeworms, 397
Coleman, William: Georges Cuvier, *review* by Prof. C. M. Yonge, 316
Collagen: Shrinkage Temperature of Eye (Dr. H. Stringer and J. Parr), 1307
Collagen and Cell Protein Synthesis by an Established Mammalian Fibroblast Line (Prof. H. Green and Prof. B. Goldberg), 347
College of Advanced Technology, Birmingham: Appointment, 827
Colless, Dr. D. H.: Fossil Diptera and Continental Drift, 402
Colliculus of Fibres Originating in the Visual Cortex: Terminal Distribution in the Superior (R. D. Lund), 1283
Collier, Dr. H. O. J., et al.: Rapid Induction by Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin, 1316
Collins, Dr. R. L., et al.: Environmental Stress and Biological Ageing, 724
Colour of Precious Opal (Dr. J. V. Sanders), 1151
Colour on the Moon (N. W. Scott), 1075
Colour Preference of the Gull Chick: Coding of the (Dr. J. P. Hailman), 710

Colthup, N. B., et *al.* : Introduction Infra-red and Raman Spectroscopy, *review* by Dr. L. J. Bellamy, 962
Columbia *SK* Group in Sciuridae in Britain : Antibodies to Viruses of the (Dr. A. D. Vizoso and R. Hay), 56
Colville, Dr. K. I., et *al.* : Lowering Effect of Neostigmine on Plasma Free Fatty Acids, 888
Colwyn Medal awarded to Dr. G. F. Bloomfield, 729
Combridge, J. H. : The Chinese Water-balance Escapement, 1175
Combustion (Dr. E. M. Bulewicz), 633
Commonwealth Mycological Institute : Retirement and Appointment of Director, 427
Commonwealth Scholarship and Fellowship Plan, Annual report, 329
Commonwealth Scientific and Industrial Research Organization in Australia, Annual Report for Division of Applied Physics 1962-63, 1142 ; Division of Physics 1962-63, 1142 ; Division of Meteorological Physics, 1142 ; Division of Tribophysics, 1142
Coal Research, 332
Communauté Européenne de l'Énergie Atomique, Euratom (seventh annual report), 833
Comparative Immunological, Biological and Biophysical Behaviour of Meningo-pneumonitis Viral Antigenic Preparations (G. C. Parikh and I. L. Shechmeister), 1013
Comparative Nutrition of Man and Domestic Animals (H. H. Mitchell), Vols. 1 and 2, *review* by Dr. D. P. Cuthbertson, 113
Compensatory Growth on Villi in Postmature Human Placentæ (Z. P. Zhemkova and O. I. Topchieva), 703
Complexing and Hydrothermal Ore Deposition (H. C. Helgeson), *review* by E. D. Lacy, 967
Composition of the Metallic Phases in some Stone and Stony-Iron Meteorites (S. J. B. Reed), 374
Compound : An Unidentified, in the Serum of Children with Kwashiorkor (Protein-Calorie Malnutrition) (Dr. R. G. Whitehead), 389
Compounds : Hydroxycinnamic Acids and Related, 928
Inhibiton of Uptake of Tritiated-noradrenaline in the Intact Rat Brain by Imipramine and Structurally Related (Dr. J. Glowinski and Dr. J. Axelrod), 1318
Comprehensive Biochemistry, Vol 15 (edited by Prof. M. Florkin and Prof. E. H. Stotz), *review* by Dr. D. T. Elmore, 219
Comptes rendus du 3ème Congrès d'Eucarpia, *review*, 978
Computation of Liquidus Relationships in Multicomponent Silicate Systems (Prof. F. G. Smith), 370
Concise Inorganic Chemistry (J. D. Lee), *review* by Prof. J. R. Partington, 511
Concrete : Glued Formwork for, 1139
"Concrete Quality", symposium on, 24
Concrete Research : Progress in (H. B. Milner), 233
Concrete Surfaces : Pop-outs on, 929
Condouris, Prof. G. A., and Shakalis, A. : Potentiation of the Nerve-Depressant Effect of Local Anæsthetics by Carbon Dioxide, 57
Conduction of the Nervous Impulse, The (Prof. A. L. Hodgkin), *review* by Dr. B. Frankenhaeuser, 1238
Cone, Dr. R. A. : Early Receptor Potential of the Vertebrate Retina, 736
Cone, Dr. R. A., and Pak, Dr. W. L. : Isolation and Identification of the Initial Peak of the Early Receptor Potential, 836
Configurational Statistics of Polymeric Chains (M. V. Volkenstein), *review* by Dr. W. R. Moore, 963
Congenital Absence of Pain, 1140
Congo Red : Paper Electrophoresis of Heat-treated Serum Albumin in the Presence of (Prof. S. Tekman and Dr. N. Öner), 287
Conjunctivitis Virus Group : Behaviour in Eggs and Tissue Culture of the Inclusion Blennorrhœa (*LB4*) Strain of the Trachoma-inclusion (Dr. N. M. Larin and J. D. Treharne), 166
Consden, Dr. R. : Paper Chromatography, Vols. 1-3, *review* 414
Conservation of Protons ina Stable Nickel Nucleus (Dr. R. Brandt), 271
Constancy Phenomenon : Illusory Perception as a (Dr. L. B. Brown and Dr. L. Houssiadas), 302 ; (Prof. R. L. Gregory), 302
Continental Drift : Fossil Diptera and (Dr. D. H. Colless), 402
Continuous-flow Micro Double Diffusion Technique with Cellulose Acetate (Mrs. C. M. Johnson, Dr. J. C. N. Westwood and Dr. M. Beaulieu), 1321
Control of Education (J. Vaizey), *review* by N. Morris, 309
Control of Hæmoglobin A and F Synthesis : Hæmoglobin Formation in Fœtal and Adult Erythroid Cells (Dr. E. R. Burka and Prof. P. A. Marks), 659
Controlled-Potential Analysis (G. A. Rechnitz), *review* by J. F. C. Tyler, 219
Convection in the Moon : A Case for (Dr. G. Fielder), 171
Cook, Dr. A. H., *Obituary* of Prof. I. A. Preece, 1035
Cook, Prof. C. Sharp : Mass of the Canyon Diablo Meteoroid, 867
Cook, M. A., et *al.* : Chemical Analysis of Proteins Low in Aromatic Amino-acids, 1088
Cooper, D. W., et *al.* : DAdelaide—a New Transferrin Variant in Man, 102
Cooper, Dr. E. H., and Inman, Dr. D. R. : Ultrastructure of Human Leucocytes synthesizing DNA, 894
Cooper, J. R., and Baxter, M. : Ink Blue as a *p*H Indicator for Certain Biological Systems, 1105
Co-Ordination Chemistry (Prof. J. Chatt), 530
Copius-Peereboom, Dr. J. W. : Thin-layer Chromatography on Polyamide Layers : Separation of Fat Antioxidants, 748
Copley Medal awarded to Prof. S. Chapman, 728, 1129
Coppens, P. : Crystal Structure of Manganese *Cyclo*pentadienide, 1298
Copper, P. : European Mid-Devonian Correlations, 363 ; *corrigendum*, 1038
Copper in Photosynthesis : Site of Action of (Prof. N. I. Bishop), 401
Coppi, B., and Sturrock, Prof. P. A. : New Model of Solar Flares, 61
Copping, Dr. A. M. : Advances in Food Research, Vol. 12, *review*, 218
Vitamins and Coenzymes, *review*, 614
Coppock, Dr. J. T. : An Agricultural Atlas of England and Wales, *review* by J. L. Beveridge, 958
Coprinus lagopus sensu Buller : Recovery of Monokaryons from Veil Cells of Fruit Bodies of (J. W. Cowan), 1113
Copulation in the Nematode *Panagrolaimus rigidus* (Schneider) : Observations on Sexual Attraction and (D. N. Greet), 96
Corbet, Dr. G. B. : A Systematic Revision of the Shrew Genus *Crocidura* in Southern Africa, *review*, 1022
Corfman, Dr. P. A., and Richart, Prof. R. M. : Chromosomes of the Ring Seal, 502
Cornelius, P. : Quantity Equations and System Variation Electricity, 173
Corner, E. J. H. : The Life of Plants, *review* by Prof. R. Good, 958
Corridors of Power (C. P. Snow), *review*, 977
Corrosion and Protection Association, 924
Cortex : Terminal Distribution in the Superior Colliculus of Fibres Originating in the Visual (R. D. Lund), 1293
Corticosteroids : Prevention of Cerebral Œdema induced by Triethyltin in Rabbits by (Dr. J. M. Taylor et *al.*), 891
Structure and Metabolism of (edited by Jorge R. Pasqualini and Max F. Jayle), *review* by Prof. J. Patterson, 411
Corticosteroids, Adrenal and Plasma, and Ascorbic Acid Content during Bone Fracture Healing (A. H. Said), 386
Cortisol-levels : Effect of Electroconvulsive Therapy on Plasma (Dr. J. R. Hodges et *al*), 754
Cortisone-antipyresis in Canine Endotoxin Fever : Hepatic Pyrogen and (Prof. T. Fukuda and K. Murata), 690
Cosenza, Dr. B. J., and Brown, Dr. J. P. : Fatty Acid Composition of Lipids extracted from Three Spherical Bacterial, 802
Cosmic Noise Absorption : A Smooth Type of (Dr. J. Ortner and W. Riedler), 1181
Cosmic-ray-induced Particle Tracks in a Meteorite (M. Maurette, P. Pellas and Dr. R. M. Walker), 821
Cosmological Red-shift (Dr. L. M. Stephenson), 1180
Cougars feeding on Mule Deer : Trophic Level Effect on the Accumulation of Cæsium-137 in (R. C. Pendleton et *al.*), 708
Coumarin by a Micro-Organism : Metabolism of : *O*-Coumaric Acid as an Intermediate between Coumarin and Melilotic Acid (Dr. C. C. Levy), 1059
O-Coumaric Acid as an Intermediate between Coumarin and Melilotic Acid : Metabolism of Coumarin by a Micro-Organism : (Dr. C. C. Levy), 1059
Council for National Academic Awards, The, 1134
Course of Higher Mathematics (V. I. Smirnov), Vols. 1 and 2, *review* by Prof. T. A. A. Broadbent, 970
Cousineau, G. H. ,and Bibring, T. : Percentage Incorporation of Leucine labelled with Carbon-14 into Isolated Mitotic Apparatus during Early Development of Sea Urchin Eggs, 805
Cowan, J. W. : Recovery of Monokaryons from Veil Cells of Fruit Bodies of *Coprinus lagopus* sensu Buller, 1113
Cowley, Prof. J. M. : Electron Diffraction Study of Evaporated Beryllia, 1082
Cows : Levels of Coenzyme *A* in the Liver of Normal Cows and of Cows suffering from Primary Ketosis (Dr. K. G. Hibbitt), 206
Cows, Thyroid Function of Friesian, during the Œstrous Cycle and in Conditions of Ovarian Abnormality (Dr. F. A. Soliman, K. Zaki, M. K. Soliman and M. S. Abdo), 693
Cox, Dr. R. P., and Griffin, Dr. M. J. : Sub-cellular Localization of Rat Kidney Alkaline Phosphatase, 476
Crab *Carcinus maenas* : Distribution of Phthalocyanine Dye (Heliogen Blue *SBL*) in Ultrastructures of Vital Dyed Axons of the (Ja. Ju. Komissarchik and S. V. Levin), 203
Crandall, L. S. : The Management of Wild Mammals in Captivity, *review* by Dr. L. Harrison Matthews, 954
Cranial Epiphyses in Mammals (Prof. A. J. E. Cave), 838
Cranmore, D., and Alpen, Prof. E. L. : Chromosomes of the Domestic Cat, 99
Creed, Dr. R. S. : *Obituary* by Dr. G. S. Dawes, 20
Creer, Dr. K. M. : Palæomagnetic Data and du Toit's Reconstruction of Gondwanaland, 369
Cresswell, R. A. : Austenite/Carbon Reaction in Cast Iron, 465
Crimes, T. P., and Sly, P. G. : Implication of Certain Sedimentary Structures within the Cambrian Succession of the St. Tudwal's Peninsula, South-west Caernarvonshire, 174
Crispens, jun., C. G., and Burns, T. A. : Electron Microscope Investigation of Lactic Dehydrogenase Agent, 1302
Crocidura in Southern Africa : A Systematic Revision of the Shrew Genus (J. Meester), *review* by Dr. G. B. Corbet, 1022
Croft, J. F. : The Mechanics of Aerosols, *review*, 1236
Crop Plants : Effect of Certain Conditions on Yield of (R. G. Fawcett), 858
Crop Yield : Plant Population and (E. F. I. Baker), 856
Crossing-over between Genes on Chromosomes : A New Theory to Explain (Prof. C. C. Lindegren), 322
Crouthamel, Carl E. (edited by) : Analytical Chemistry, Vol. 3, Parts 4-7, *review* by A. A. Smales, 8
Crowther, Dr. A. F. : Cyanine Dyes and Related Compounds, *review*, 312
Croxatto, Héctor, et *al.* : Luteinizing Hormone-like Activity in Human Median Eminence Extracts, 584
Croxatto, Prof. Héctor, and de la Lastra, M. : Ovarian Ascorbic Acid Depleting Activity in Human Brain Extracts, 583
Croxatto, Prof. Horacio, et *al.* : Luteinizing Hormone-like Activity in Human Median Eminence Extracts, 584
Cruickshank, B., et *al.* : Human Histology, *review* by E. H. Leach, 977
"Crustacea", symposium, 925
Crustal Blocks under Tectonic Stresses : Model Studies of Elastic Wave Propagations in (Dr. V. S. Tuman), 65
Cryostat Method for the Extraction of Soluble Tissue Components (D. E. H. Tee, M. Wang and J. Watkins), 682
Crystal Structure of Hydroxyapatite (Dr. M. I. Kay, Prof. R. A. Young and Dr. A. S. Posner), 1050
Crystal Structure of Lamprophyllite (Dr. P. J. Woodrow), 375
Crystal Structure of Manganese *Cyclo*pentadienide (P. Coppens), 1298
Crystal Structure and Electrical Properties of some Cobalt-group Chalcogenides (Dr. F. Hulliger), 644
Crystalline *β*-Nigerose (Dr. F. Yamauchi and K. Matsuda), 1088
Crystallographic Course held in Peking, 1038
Crystals : Mechanical Twinning of (M. V. Klassen-Neklyudova), *review* by Dr. J. H. Brunton, 613
Crystals from the Melt in Glass Tubes : Growth of (D. Kirtisinghe and Dr. R. F. Strickland-Constable), 465

Deciduoma Method : Assay of Gonadotrophins by the (N. Kovačič), 385
Declination Limits : Standard Date Periods with (Dr. H. Heywood), 768
Deleu, Dr. J., and Bohr, Dr. H. : Uptake of Tetracycline by Human Bone *in vitro*, 1103
Deltaic and Shallow-Marine Deposits : Proceedings of the Sixth International Sedimentological Congress, 1963 (edited by L. M. J. U. van Straaten), *review* by Prof. C. F. Davidson, 418
Deltaic and Shallow-water Littoral Marine Deposits (edited by V. S. Yablokov *et al.*), *review* by Prof. C. F. Davidson, 418
Demczynski, S. : Automation and the Future of Man, *review* by A. Albu, 3
Demonstration of Syngeneic Preference *in vitro* (K. E. Hellström and G. Haughton), 661
Denis, A. : Cats of the World, *review* by Dr. L. Harrison Matthews, 1023
Dennis, Dr. R. W. G. : Antibiotic-producing Microscopic Fungi, *review*, 8
Iconographia Mycologica, VIII, IX and X, *review*, 316
Denniston, C., and Johnson, F. M. : Genetic Variation of Alcohol Dehydrogenase in *Drosophila melanogaster*, 906
Dentifrice Fluoride : Distribution and Excretion of (R. Duckworth), 489
Denton, Dr. E. J., appointed to a Royal Society Research Professorship, 925
Deoxyribonucleic Acid : Recovery from Sub-lethal X-ray Damage of Mammalian Cells during Inhibition of Synthesis of (J. H. Kim *et al.*), 598
Specificity of the Interactions between Histones and (E. W. Johns and Prof. J. A. V. Butler), 853
Ultrastructure of Human Leucocytes synthesizing (Dr. E. H. Cooper and Dr. D. R. Inman), 894
DNA in the Nuclei of the Adrenal Medulla of Rats exposed to Cold : Marked Decrease of (M. Viola), 1094
Deoxyribonucleic Acid in Plant Nucleoli (Dr. J. McLeish), 36
DNA is not coupled to Histone in these Protozoa : Antigenicity of *Trypanosome* Nuclei : Evidence that (Dr. J. S. Beck and Dr. P. J. Walker), 194
DNA and of its Complex with Acridine Orange under Streaming Conditions . Optical Rotatory Power of (Dr. S. F. Mason and Dr. A. J. McCaffery), 468
Deoxyribonucleic Acid and Ribonucleic Acid and its Biological Significance : Binding of Proflavine to (Dr. C. Scholtissek and Dr. R. Rott), 39
Department of Scientific and Industrial Research : *Ergonomics for Industry*, No. 6, *Noise in Industry*, 338
National Engineering Laboratory Report No. 165, 733
The Film in Scientific Research : *Report of a Working Party*, 433
Research for Industry, 1963, 307, 334
Road Research 1963, 1040
Road Research Laboratory, Technical Paper No. 67, 234
Report of the Tropical Products Institute, 134
Department of Technical Co-operation. *Research Assistance for the Developing Countries*, (Cmnd. 2433.), 718
Tenth Report from the Estimates Committee, 1963-64, 715, 1121
Depth Surveys in the Mediterranean and Red Sea : Magnetic, Gravity and (T. D Allan *et al.*), 1245
Depolymerase : Breaking of Immunological Paralysis by Injection of a Specific (M. S. Brooke), 1319
Derry, Prof. L. W. : The Science and Technology of Tungsten, Tantalum, Molybdenum, Niobium and Their Alloys, *review*, 966
Dersjant, H., and Balner, Dr. H : Early Lymphatic Regeneration in Thymectomized Radiation Chimeras, 941
Desferrioxamine-B : Prevention of Plutonium Deposition by (Dr. V. H. Smith), 899
Desmethylimipramine Mortality in Mice : Effect of Altered Thyroid Status on (A. J. Prange, jun., *et al.*), 1204
Destruction of Homologous Cells in Tissue Culture by Nuclei of Immune Lymphocytes (Dr. G. J. Svet-Moldavsky and I. J. Chernyakhovskaya), 799
Desty, D. H. : Experimental Methods in Gas Reactions, second edition, *review*, 965
Detection of 'Activated 'Compounds on Paper (D. E. Briggs, Dr. D. J. Millin and M. J. Saltmarsh-Andrew), 286
Detection of an Interstellar Flux of Gamma-rays (Dr. A. E. Metzger, Dr E. C. Anderson, Prof. M. A. van Dilla and Prof. J. R. Arnold), 766
Detection of the Onset of Instability in a Cylindrical Magnetohydrodynamic Flow (J. A. Baylis), 563
Deutan Genes ; Recombination between Protan and : Data on their Relative Positions in Respect of the G6PD Locus (M. Siniscalco *et al.*), 1062
Devanandan, Dr. M. S., *et al.* : Presynaptic Inhibition induced by Muscle Stretch, 996
Developing Countries : British Aid to, 1121
Development Decade : Planning for the, 107
Development of Northern Australia, 26
Devine, J. R., *et al.* : Stability of Granular Dicalcium Phosphate Dihydrate in Soil, 1114
Dhaliwal, Dr. S. S., and Griffiths, Dr. D. A. : Histological Reactions of *Bufo melanostictus* to Culture Filtrates and Mycelial Extracts of a Pathogenic Fungus, 345
Di-t-butyl Nitroxide and Analogues : Sensitization of Anoxic Bacteria to X-rays by (Dr. P. T. Emmerson and Dr. P. Howard-Flanders), 1005
Diabetic Subjects on Incorporation of Glucose I-Carbon-14 into Individual Fatty Acids of Rat Adipose Tissue : Effect of Serum from Normal and (Prof. A. R. Hennes *et al.*), 943
Diagnosis of Auto-immunity (M. N. Rashad, Dr. W. R. M. Morton and N. P. Bishun), 393
Diamond, Dr. S. : Rapid Reaction of Lime with Hydrous Alumina, 183
Diazo-gamma-globulins : Immunochromatographic Partition of Soluble Antigens on Columns of Insoluble (Dr. S. DeCarvalho *et al.*), 265
Dicalcium Phosphate Dihydrate in Soil : Stability of Granular (S. Larsen *et al.*), 1114
Di Chiro, Dr. G. : Movement of the Cerebrospinal Fluid in Human Beings, 290
2, 4-Dichlorophenoxyacetic Acid in the Stem Tissue of *Phaseolus vulgaris* : Metabolic Fate of (Dr. E. W. Thomas *et al.*), 884
Dichotomous Replications of the *Bacillus subtilis* Chromosome during Spore Germination : Synchronous and (M. Oishi *et al.*), 1069
Dickinson, Dr. L., and Stuart-Harris, Prof. C. H. : The Background to Chemotherapy of Virus Diseases *review* by Sir Christopher Andrewes, 959
Dickinson, T., *et al.* : Photodimerization in Crystalline 9-Cyanoanthracene, 876
Diet and Human Bone from San Juan, Puerto Rico : Radium-226 in (N. A. Hallden and Dr. J. H. Harley), 240
Diet and Iodine-131 Injections on the Survival of Dystrophic Mice : Influence of (R. F. Borgman), 389
Dieterman, L. J., *et al.* : Scopoletin, Scopolin and Chlorogenic Acid in Tumours of Interspecific *Nicotiana* Hybrids, 779
Diethylsulphate : Treatment of Seeds with Ethylmethansulphonate and (M. L. Belli and T. Cervigni), 1199
Dietz, Dr. R. S., and Butler, L. W. : Shatter-cone Orientation at Sudbury, Canada, 280
Differential Plasma Turbidity as an Index of Platelet Count (J. F. Newcombe) 87,
Diffusion Constants of Proteins determined by a Multi-unit Analytical Method (A. Polson and G. M. Potgieter), 379
Diffusion Technique with Cellulose Acetate : Continuous-flow Micro Double (Mrs. C. M. Johnson *et al.*), 1321
Diglyceride/Triglyceride Interrelationships in Thyroid Tissue : Effect of Pituitary Thyrotrophin on the (Prof. N. Freindel and T. W. Scott), 1313
4-Dimethylaminoazobenzene : Partial Protection by an Ox Liver Extract against Rat Liver Carcinogenesis by (Dr. G. Fare), 1004
9 10-Dimethyl-1,2-Benzanthracene : Tumour Specific Immunity against Murine Epitheliomas induced with (Mrs. M. A. Tuffrey and Dr. J. R. Batchelor), 349
Dingle, J. T., and Lucy, Dr. J. A. : Fat-soluble Vitamins and Biological Membranes, 156
Dinitrophenol of Potassium Absorption in Carrot Root Tissue Cultures : Sensitivity to (A. G. Smithers and Prof. J. F. Sutcliffe), 1330
DiPaolo, Dr. J. A. : Effect of Cigarette-smoke Condensates on Homografts of Neonatal Lung Tissue in Mice, 1159
Dipeptidase Activities : Determination of (L. Josefsson), 783
Dipteran Salivary Glands : Effect of Benzamide and Substituted Benzimidazoles on : Sequential and Reversible Inhibition of Synthesis of Ribonucleic Acid in the Nucleolus and Chromosomes (Dr. J. L. Sirlin and Dr. J. Jacob), 545
Dipyrrylvinyl Pyridines as Trichuricides (Dr. A. P. Phillips and Prof. R. B. Burrows), 892
Dirac, Prof. P. A. M. : Equivalence of the Schroedinger and Heisenberg Pictures, 771
Directional Property of Electrode Surfaces (D. G. Wyatt), 1294
Disarmament and the Role of the Scientist, 1233
Discharge Patterns of Elements in Cat Cerebellar Cortex, and their Responses to Iontophoretically Applied Drugs (I. McCance and Dr. J. W. Phillis), 844

Discovery or Invention? (Inaugural Lecture delivered by Prof. I. D. Rattee), 1017
Distribution of Cobalt-60 in the Rat as influenced by Chelating Agents (Dr. D. Khuong Lê), 696
Distribution and Excretion of Dentifrice Fluoride (R. Duckworth), 489
Distribution and Motions of OH near the Galactic Centre (J. G. Bolton, F. F. Gardner, R. X. McGee and B. J. Robinson), 30
Disulphide Bonds of Soy Bean Trypsin Inhibitor : Reduction and Re-oxidation of the (R. F. Steiner), 579
Dithiocarbamate Fungicide : Influence of Excreted Substance from Leaves on Decomposition of Zineb, a (Prof. A. Kovács and N. J. A. Cucchi), 1090
Diurnal Nutation of the Earth : Nearly (Dr. R. O. Vicente and Sir Harold Jeffreys), 120
Diurnal Rhythms : The Physiology of (J. E. Harker), *review* by Dr. F. J. Ebling, 817
Dixon, G. J., *et al.* : Antiviral Activity of Gliotoxin and Gliotoxin Acetate, 1333
Dixon, Dr. P. S. : *Asparagopsis* in Europe, 902
Dizygotic Twins with XX/XY Chimerism (Dr. I. A. Uchida, H. C. Wang and Dr. M. Ray), 191
Djerassi, Prof. C., *et al.* : Interpretation of Mass Spectra of Organic Compounds, *review* by Dr. F. G. Mann, 965
Structure Elucidation of Natural Products by Mass Spectrometry, Vol. I, *review* by Dr. J. Harley-Mason, 1237
Doane, W. M., *et al.* : A Unique Sugar Orthoester, 186
Dodd, Prof. M. C., *et al.* : Chemical Aspects of Inhibitors of Rh$_0$(D) Antibody, 549
A New Class of Antimicrobial Agents, 697
Dodds, T. C., *et al.* : Human Histology, *review* by E. H. Leach, 977

EAGLE, D. J. : Simple Estimation of Soluble Salts in Glasshouse Soils, 1227
Early Lymphatic Regeneration in Thymectomized Radiation Chimeras (Dr. H. Balner and H. Dersjant), 941
Earth : Nearly Diurnal Nutation of the (Dr. R. O. Vicente and Sir Harold Jeffreys), 120
Speculation on the Origin and Non-symmetry of Two Thin Layers *D''* and *F* Embracing the Liquid Core inside the (Dr. V. S. Tuman), 1146
Earth Conditions: Synthesis of Pyrophosphate under Primitive (Prof. S. L. Miller and M. Parris), 1248
Earth Satellites : Torques and Attitude Sensing in (edited by F. Singer), *review* by W. G. Hughes 973
Earth's Moment of Inertia : Changes in the (Prof. S. K. Runcorn), 823
Earthquake, Grand Banks, of 1929 and the 'Instantaneous' Cable Failures (S. S. Gupta), 674
Earwig, *Labidura riparia truncata* (Dermaptera : Labiduridae) : Independent Development of the Male Gonads and Vasa Deferentia, and the Genitalia of the Australian (Dr. E. T. Giles), 1109
East African Common Services Organization. Annual Report of the East African Marine Fisheries Research Organization, 1963, 529
Eberhardt, L. L. : Variability of the Strontium-90 and Cæsium-137 Burden of Native Plants and Animals, 238
Ebling, Dr. F. J. : The Physiology of Diurnal Rhythms, *review*, 817
Eccles, Sir John, *et al.* : Golgi Cell Inhibition in the Cerebellar Cortex, 1265
Eccles, Sir John : The Physiology of Synapses, *review* by Prof. A. S. V. Burgen, 412
Eccles, R. M., *et al.* : Presynaptic Inhibition induced by Muscle Stretch, 996
Echinoids : Axial Organ and Fluid Circulation in (Prof. N. Millott and Dr. H. G. Vevers), 1216
Hæmal System of Regular (M. P. M. Burton), 1218
Eckenfelder, Prof. W. W., *et al.* (edited by) : Advances in Water Pollution Research, Vols. 1-3, *review* by A. L. Downing, 817
Eclipse of the Moon, December 19, 925
Ecology of Rocky Shores (Dr. J. R. Lewis), *review* by Prof. C. M. Yonge, 313
Economic Development (Prof. J. K. Galbraith), *review* by R. Brightman, 1024
Economics and Sociology of Industry (Prof. P. S. Florence), *review* by Prof. T. W. Hutchison, 718
Eddington, The Arthur Stanley, Memorial Lecture, will be given by Dame Kathleen Lonsdale, 231
Edels, Prof. H. : Physics of Atomic Collisions, *review*, 980
Education : Responsibility and, 409
Education, the Financing of, 22
Education and Environment (S. Wiseman), *review* by J. Bradley, 976
Education and Research in Oral Science in the Massachusetts Institute of Technology, 631
Educational and Social Failure : Some Further Observations (J. Bradley), 132
Efremov, G., *et al.* : Abnormal Hæmoglobin in Sheep, 700
Egan, H. : Symposium on Instrumentation for the Detection and Determination of Pesticides and their Residues in Foods (Residue Reviews, Vol. 5), *review*, 419
Egerton, Dr. G. S. : Photosensitizing Properties of Dyes and White Pigments, 1153
Eggs : Use of a Fluorescent Brightener for tracing the Passage of *Salmonella* in (Dr. A. M. Paton and Prof. J. C. Ayres), 803
Eggs and Tissue Culture of the Inclusion Blennorrhœa (*LB4*) Strain of the Trachoma-inclusion Conjunctivitis Virus Group : Behaviour in (Dr. N. M. Larin and J. D. Treharne), 166
Ehrenberg, L., *et al.* : Tritium Labelling of Antibodies, 796
Ehrlich, J., *et al.* : Antiviral Activity of Gliotoxin and Gliotoxin Acetate, 1333
Ehrlich Ascites Carcinoma Cells Grown in Mice on a Meat Diet : Metabolism of (J. Ilan and R. M. Johnstone), 1061
Ehrlich Ascites Tumour Cells : Isolation of a Mucopeptide from the Surface of (O. K. Langley and Dr. E. J. Ambrose), 53
Eidinoff, Prof. M. L., *et al.* : Recovery of Sub-lethal X-ray Damage of Mammalian Cells during Inhibition of Synthesis of Deoxyribonucleic Acid, 598
Einstein-shift Photoelectrically : On a Possibility of measuring the (M. Frick), 1076
Ejaculation in the Bull and Ram : Mechanism of Erection and (J. W. Watson), 95
El Agib, A. A. R. : A General Expression for the Isentropic Stagnation Temperature of a Fluid, 989
Elastic Wave Propagations in Crustal Blocks under Tectonic Stresses : Model Studies of (Dr. V. S. Tuman), 65
Elastolysate Test : A Specific (Prof. M. Yenson, H. Öz and N. Baban), 473
Electric Current : The *in situ* Detection of an Ionospheric (Dr. K. Burrows and Dr. S. H. Hall), 721
Electric Currents on Bone *in vivo* : Effects of (Prof. C. A. L. Bassett, R. J. Pawluk and R. O. Becker), 652
Electric Fields : Aggregation of Ice Crystals in Strong (Dr. J. Latham and C. P. R. Saunders), 1293
Electrical Conduction in Thin Aggregated Metal Films (Dr. R. M. Hill), 35
Electrical Engineering : Tensors in (J. W. Lynn), *review* by Dr. W. J. Gibbs, 112
Electrical Network Theory : Matric and Tensor Analysis in (S. Austen Stignant), *review*, 114
Electrical Research Association, 43rd Annual Report, 1963, 28
Electrical Research Association (Prof. J. Greig), 28
Electricity : Quantity Equations and System Variation in (P. Cornelius), 173
Electrochemistry, fifth Seminar, 1141
Electroconvulsive Therapy on Plasma Cortisol-levels : Effect of (Dr. J. R. Hodges, Dr. M. Jones, Dr. A. Elithorn and Dr. P. Bridges), 754
Electrode Surfaces : Directional Property of (D. G. Wyatt), 1294
Electroencephalogram and a Stabilized Retinal Image : Alpha-frequency of (C. R. Evans and Dr. G. K. Smith), 303
Electroencephalograph during 'Feigned' Sleep in the Opossum (Dr. A. C. Norton, A. V. Beran and (the late) Prof. G. A. Misrahy), 162
Electrolyte-depleted Muscle Fibres : Membrane Potential of (Dr. R. P. Kernan), 83
Electron Diffraction Study of Evaporated Beryllia (Prof. J. M. Cowley), 1082
Electron Flux at 1,000 km Altitude from Electron Content Measurement at Mid-latitudes : Downward (P. R. Arendt and H. Soicher), 983
Electron Microscope Investigation of Lactic Dehydrogenase Agent (C. G. Crispens, jun., and T. A. Burns), 1302
Electron-microscopical Localization of Products from Histochemical Reactions used to detect Cholinesterase in Muscle (Dr. R. Miledi), 293
Electron Microscopy : Modern Developments in (edited by B. M. Siegel), *review* by L. M. Brown, 979
Sub-units of the Catalase Molecule seen by (Dr. R. C. Valentine), 1262
"Electron Microscopy in Far East and Oceania", second regional conference, 1258
Electron Paramagnetic Resonance in Spinach Chloroplasts at Low Temperature (Prof. P. Sogo, R. Faucett and T. Holzer), 1076
Electron Spin Resonance of β-Phenylhydroxylamino-β-methyl-pentane-δ-phenyl-imine Oxide (Dr. V. S. Griffiths and G. R. Parlett), 69
Electron Spin Resonance Signals from Surviving Tumour Tissues and from their Corresponding Normal Tissues : Differences observed between (Dr. J. R. Mallard and Dr. M. Kent), 1192
Electron Spin Resonance Spectrometer : Use of Long Cavities for Aqueous Biological Tissue Samples in an (M. Kent and Dr. J. R. Mallard), 396
Electron Temperature in a Laser-heated Plasma (E. Archbold and T. P. Hughes), 670
Electron Transfer in Irradiated Vacuum Cavity Chambers (Dr. T. E. Burlin and S. R. Husain), 563
Electron Transport Pathway of Nitrate Reductase : Use of Mutants to study the (G. J. Sorger), 575
"Electronic States of Biological Macromolecules", Informal open meeting, 1038
Electronic Structure of Molecules (J. W. Linnett), *review* by Prof. A. Maccoll, 979
"Electronics Design", conference on, 1258
L'Electronique dans les Appareils de Contrôle Nucléaire, Tome I (Georges Nicolo), *review* by J. F. Hogg, 8
Electrons : Pulsed Radiolysis of *Cyclo*hexane Solutions : Evidence for Reactions of (Dr. G. Scholes *et al.*), 1187

Electrons, Low-energy, in an Irradiated Vacuum Cavity Chamber : Measurement of the Emission of (Dr. T. E. Burlin and S. R. Husain), 1078
Electropherograms : Detection of Enzymes in Agar (Dr. C. Poort and W. J. W. van Venrooy), 684
Electrophoresis : An Investigation of Soluble Ribonucleic Acid by Zone (Dr. E. G. Richards and Dr. W. B. Gratzer), 878
Qualitative Estimation of Erythrocyte Catalase by Starch-gel (Dr. E. Kleihauer and Mrs. G. Brandt), 478
Electrophoresis of an Insect Inorganic Pyrophosphatase (Dr. E. N. Lambremont and R. M. Schrader), 883
Electrophoretic Behaviour of Serum Angiotensinase (Dr. D. Klaus and Dr. P. Biron), 381
Electrophoretic Patterns of Lysed Fibrin formed by Homologous and Heterologous Thrombin (Dr. F. Nour-Eldin), 995
Electrophoretic and Chromatographic Heterogeneity of Pituitary Hormones : Possible Cause of (Dr. M. Sluyser), 574
Electroplating : Handbook of Industrial (E. A. Ollard and E. B. Smith), third edition, *review* by Capt. J. Fox-Williams, 816
Electroshock Seizures in Rats at High Altitude : Brain Maturation Measured by (Prof. L. M. Heim and Prof. P. S. Timiras), 1157
Eley, Prof. D. D. : Progress in the Science and Technology of the Rare Earths, Vol. I, *review*, 1018
Elithorn, Dr. A., *et al.* : Effect of Electroconvulsive Therapy on Plasma Cortisol-levels, 754
El Khalifa, Dr. M. D. : Aminothioamides as Protectors against the Effect of Gamma-rays in *Allium cepa*, 708
Elliott, P., *et al.* : The Chinese Water-balance Escapement, 1175
Ellipsometer Recordings of Changes in Optical Thickness of Adsorbed Films associated with Surface Activation of Blood Clotting (Dr. L. Vroman and A. Lukosevicius), 701
Ellis, Prof. G. R. A. : Spectra of the Galactic Radio Emissions, 171
Ellis, G. R. A., and Hamilton, P. A. : Absorption of Radio Waves in the Galaxy, 272
Ellis, Dr. J. R. : Chromosomes and Human Malformation, 930
Elmore, Dr. D. T. : Comprehensive Biochemistry, Vol. 15, *review*, 219
Elucidation of the Biosynthetic Pathway of Thyroidal 3 : 5 : 3′ Triiodothyronine by Means of Isotope Position Experiments (Dr. L. G. Plaskett and Dr. C. F. Barnaby), 1271
Embryo : Species Specificity of the Immunogenic Complexes of the Tapeworm Hexacanth (Dr. M. A. Gemmell), 705
Embryo and Endosperm of *Prunus persica* : Kinins in the (Prof. L. E. Powell and C. Pratt), 602
Embryonic Development : Effects of Histones on (Prof. J. Brachet), 1218
Embryonic Hypersensitivity and its Relation to the Level of Differentiation of the Chick : Duration of (Prof. P. J. Van Alten), 797
Embryos : Effect of the Implantation Site on the Development of Grafted Limb Bud Mesoderm in Chick (R. Amprino and D. A. Bonetti), 298
Embryos from Anthers of *Datura* : *In vitro* Production of (S. Guha and S. C. Maheshwari), 497
Embryos of *Amyema*, *Amylotheca*, and *Scurrula* on Synthetic Media : Growth of (Dr. B. M. Johri and Dr. Y. P. Singh Bajaj), 1220
Emeléus, H. J., and Sharpe, A. G. (edited by) : Advances in Inorganic Chemistry and Radiochemistry, Vol. 5, *review* by Dr. D. W. A. Sharp, 418
Emmerson, Dr. P. T., and Howard-Flanders, Dr. P. : Sensitization of Anoxic Bacteria to X-rays by Di-t-butyl Nitroxide and Analogues, 1005
Encephalitogenic Protein from Bovine Cord : Isolation of a Highly Purified (Dr. R. F. Kibler *et al.*), 1273
Encephalomyelitis in Rats and Chickens treated with Reserpine : Suppression of Experimental Allergic (Prof. B. D. Janković, Dr. M. Draškoci, D. Paunović and L. Popesković), 1101
Encephalomyocarditis Virus and the Synthesis of Single- and Double-stranded RNA by the Isolated Polymerase : Development of Ribonucleic Acid Polymerase in Cells infected with (Dr. E. Horton *et al.*), 247
Endosperm of *Prunus persica* : Kinins in the Embryo and (Prof. L. E. Powell and C. Pratt), 602
Endotoxin : Patterns of Interferon Appearance in Mice injected with Bacteria or Bacterial (Prof. W. R. Stinebring and Prof. J. S. Youngner), 712
Endotoxin Fever : Heptatic Pyrogen and Cortisone-antipyresis in Canine (Prof. T. Fukuda and K. Murata), 690
Endotoxin Shock : Development of Shock-inducing Factor in Canine (Prof. T. Fukuda *et al.*), 585
"Energy Transfer in Radiation Processes", symposium, 830
Eng, Dr. L-I. L. : Alkaline Phosphatase Activity of the Leucocytes in Animals, 191
Eng, Dr. L-I. L., and Chin, J. : Abnormal Hæmoglobin and Glucose-6-phosphate Dehydrogenase Deficiency in Malayan Aborigines, 291
Eng, Dr. L-I. L., and Giok, P-O. H. : Glucose-6-phosphate Dehydrogenase Deficiency in Indonesia, 88
English, C. T., *et al.* : A Second Example of ---/--- Blood or Rh_{null}, 892
Enterline, Prof. H. T., *et al.* : Sedimentation Rate of Cells in Metaphase as compared with Cells in Interphase, 1225
Enteropneusta : Choanocytes in the Skin of *Harrimania kupfferi* (Dr. A. Nørrevang), 398
Entomological Society of Canada : 1964 Gold Medal Awarded, 1038
Environment : Imprinting to a Static Feature of the Home (A. Taylor and K. F. Taylor), 1117
Environmental Group, inaugural meeting, 730
Environmental Stress and Biological Ageing (Dr. J. M. Ordy, C. Rolsten, Dr. T. Samorajski and Dr. R. L. Collins), 724
Enyi, B. A. C. : Factors affecting the Emergence of Primary Tillers from the True Leaves of the Main Shoot of a Rice Plant, 495
Enzymatic Basis of the Respiratory Stimulation during Phagocytosis (Dr. R. H. Cagan and Prof. M. L. Karnovsky), 255
Enzymatic Changes in Muscle due to Ageing : Structural and (Dr. A. K. Susheela), 296
Enzymatic Inhibitors (Potassium Cyanide and Sodium Fluoride) on Muscle Fibre Sensitivity to Potassium Ion : Action of (Prof. G. Valette and K. Ozan), 586
Enzymatic Oxidation of Galactose-6-phosphate (T. Inouye, J. A. Schneider and Prof. D. Y. Hsia), 1304
Enzyme : Lysogenic Conversion in *Staphylococcus aureus*, to a Change in the Production of Extracellular 'Tween'-splitting (Dr. K. Rosendal *et al.*), 1222
Enzyme Catalysis : Mechanisms of (Prof. G. G. Hammes), 342
Enzyme Preparation from Iron-chlorotic Barley (*Hordeum vulgaris*) Seedlings : Catalase Activity of a Crude (S. Kotaka *et al.*), 1198
Enzymes : Degradation of Type XIV *Pneumococcus* Polysaccharide by Induced (Dr. S. A. Barker *et al.*), 938
Enzymes in Agar Electropherograms : Detection of (Dr. C. Poort and W. J. W. van Venrooy), 684
Enzymes in Blood Plasma (B. Hess), *review* by Dr. H. Lehmann, 215
Epidemic Theory : Generalization of (Dr. W. Goffman and Dr. V. A. Newill), 225
Epidemics and Rumours (D. J. Daley and Prof. D. G. Kendall), 1118
Epilepsy in Africans, 735
Epinephrine to affect Glycogen-levels in the Isolated Rat Liver : Failure of Physiological Concentrations of (Prof. J. E. Sokal and Dr. E. J. Sarcione), 881
Epiphyses in Mammals : Cranial (Prof. A. J. E. Cave), 838
Epiphysis of *Xenophus laevis* : Uptake of Labelled Precursors of Melatonin by the (H. M. Charlton), 1093
Epitheliomas induced with 9,10-Dimethyl-1,2-Benzanthracene : Tumour Specific Immunity against Murine (Mrs. M. A. Tuffrey and Dr. J. R. Batchelor), 349
Epstein, Dr. S. S., *et al.* : Charge-transfer Complex Formation, Carcinogenicity and Photodynamic Activity in Polycyclic Compounds, 750
Equatorial Undercurrent in the Western Indian Ocean (Dr. J. C. Swallow), 436
Equivalence of the Schroedinger and Heisenberg Pictures (Dr. H. S. Perlman), 771 ; (Prof. P. A. M. Dirac), 771
Erb, jun., W. H., *et al.* : Sedimentation Rate of Cells in Metaphase as compared with Cells in Interphase, 1225
Erection and Ejaculation in the Bull and Ram : Mechanism of (J. W. Watson), 95
Eren, J., *et al.* : Carbon dioxide dependent Morphogenesis in *Arthrobotrys conoides*, 804
Ericsson, R. J., *et al.* : Progesterone and 6-Chloro-Δ^6-17-Acetoxyprogesterone as Inhibitors of Spermatogenesis in the Rabbit, 261
Erma, V. A., *et al* : Evidence of Whistler Guidance by Magneto-ionic Ducts of Poory-defined Structure, 1182
Erythroblasts in Baboons : Reticulo-endothelial Cells as 'Nurses' for Plasma Cells and (Dr. H. Foy and A. Kondi), 293
Erythrocyte Catalase by Starch-gel Electrophoresis : Qualitative Estimation of (Dr. K. Kleihauer and Mrs. G. Brandt), 478
Erythrocytes : Adenosine-triphosphatase and Potassium Retention in X-irradiated (D. K. Myers and L. Levy), 1324
Lactic Dehydrogenase Isozymes and Ageing of (J. Rosa and F. Schapira), 883
Erythrocytes with the Individual's Age : Changes in the Human A Antigen of (Dr. F. J. Grundbacher), 192
Erythrocytes and the Liquefying of Clotted Amphibian Blood *in vitro* (Dr E. Hachett and C. Hann), 590
Erythroid Cells : Control of Hæmoglobin A and F Synthesis : Hæmoglobin Formation in Fœtal and Adult (Dr. E. R. Burka and Prof. P. A. Marks), 659
Simple Separation of Rabbit Marrow Myeloid Cells from (Prof. J. W. Archdeacon *et al.*), 996
Erythromycin and Tetracycline in Human Bone-marrow Cultures : Effects of (Dr. M. R. Vas, Dr. B. Bain and Prof. L. Lowenstein), 1100
Erythropoietic Response in the Rhesus Monkey : Effects of Hypothalamic Stimulation on the (Prof. E. A. Mirand *et al.*), 1163
Erythropoietin : Ability of Tamarins to Produce and Respond to (Prof. E. A. Mirand *et al.*), 1064
E. coli : Action of D-Tryptophan on (M. Hatanaka), 202
E. coli obtained by the Lytic Enzyme isolated from Phage T_2 : Sphæroplasts of (D. M. Goldfarb *et al.*), 1331
Essex Hall Lecture by Prof. J. Rotblat, 1233
Esso Magazine (13, No. 3, 1964), 1139
Ester and Sodium Salt : Isotope Effects in the Infra-red Spectra of some Carbon-14-labelled Acids, an (B. H. Baxter and A. F. C. Horsler), 675
Esterase Activity of Pepsin (L. A. Lokshina, Prof. V. N. Orekhovich and V. A. Sklyankina), 580
Esters of Trimethoxybenzoic Acid : Inhibition of Synthesis of Acetylcholine by some (Dr. S. P. Bhatnagar *et al.*), 485
Estimating the Malthusian Parameter from Census Data (L. P. Lefkovitch), 810
Estimation of Half-lives from Meteoritic Data (Dr. M. E. Lipschutz), 1289
Ethanol : Iodine as a Scavenger for Hydrogen Atoms in Irradiated (N. T. Barker and Prof. J. H. Green), 872
Ethylene : Genesis and Biogenesis of (Dr. M. Lieberman and Dr. L. W. Mapson), 343
Ethylene by Carnations : Effect of Damage and Fungal Infection on the Production of (W. H. Smith *et al.*), 92
Ethylene Oxide an Antagonist of Ethylene in Metabolism (M. Lieberman, S. Asen and Dr. L. W. Mapson), 756
Ethylene Production by a Sub-cellular Fraction from Tomatoes : Effects of Nitrogen, and of Respiratory Inhibitors, on (M. Meheriuk and Prof. M. Spencer), 43
Ethylmethansulphonate and Diethylsulphate : Treatment of Seeds with (M. L. Belli and T. Cervigni), 1199
Etkin, W. (edited by) : Social Behaviour and Organization among Vertebrates, *review* by Dr. W. H. Thorpe, 513
Ettlinger, Dr. G., and Moffatt, A. : Lateral Preferences in the Monkey, 606
European Atomic Energy Community, seventh annual report, 833
European Mid-Devonian Correlations (P. Copper), 363 ; *Corrigendum*, 1038
Evans, C. R., and Smith, Dr. G. K. : Alpha-frequency of Electroencephalogram and a Stabilized Retinal Image, 303
Evans, Dr. C. R., and Tarney, Dr. J. : Isotopic Ages of Assynt Dykes, 638
Evans, Dr. J. E. : The Optical Model of Elastic Scattering, *review*, 211
Evans, Dr. S., *et al.* : Radio Echo Sounding of Polar Ice Sheets, 420
Evenari, Prof. M. : Hardening Treatment of Seeds as a means of increasing Yields under Conditions of Inadequate Moisture, 1010
Evolution : Classification and Human (edited by Sherwood L. Washburn), *review* by Sir Wilfrid Le Gros Clark, 951
Evolution of Man (G. H. R. von Koenigswald), *review* by J. Hawkes, 952
Evolutionary and Genetic Biology of Primates (edited by John Buettner-Janusch), Vols. I and 2, *review* by Sir Solly Zuckerman, 949
Excitons : Theory of (R. S. Knox), *review* by R. Loudon, 1024
Excreted Substance from Leaves on Decomposition of Zineb, a Dithiocarbamate Fungicide : Influence of (Prof. A. Kovács and N. J. A. Cucchi), 1090
Excretion of Dentifrice Fluoride : Distribution and (R. Duckworth), 489
Exocrine Secretion from the Isolated Rabbit Pancreas (Dr. S. S. Rothman), 84
Experimental Methods in Gas Reactions, second edition (Sir Harry Melville and B. G. Gowenlock), *review* by D. H. Desty, 965
Experimental Post-traumatic Dystrophy in the Rabbit (Dr. P. Krediet), 538
Extracellular 'Tween'-splitting Enzyme : Lysogenic Conversion in *Staphylococcus aureus*, to a Change in the Production of (Dr. K. Rosendal *et al.*), 1222
Extra-terrestrial Synthesis of Straight-chain Hydrocarbon : Possible Mechanism for the (Dr. C. B. Johnson and Prof. A. T. Wilson), 181
Extrathermal Electrical Conductivity Measurements in a Magnetoplasmadynamic Generator (I. R. McNab), 275
Eye Collagen : Shrinkage Temperature of (Dr H. Stringer and J. Parr), 1307
Eye, Formation of Isorhodopsin in the Frog's, during Continuous Illumination (T. Reuter), 784
Eyles, Dr. V. A. : Minerals and Rocks, *review*, 719
The Study of Fossils, *review*, 719
Les volcans et leur Activité, second edition, *review*, 719
Eyring, LeRoy (edited by) : Progress in the Science and Technology of the Rare Earths, Vol. I, *review* by Prof. D. D. Eley, 1018
Eyssen, Dr. H., *et al.* : Influence of Basic Antibiotics on Serum- and Liver-cholesterol Concentrations in Chicks, 1306

FABULOUS Isotopes, The (R. McKown), *review* by Dr. W. L. Sumner, 1241
Factors affecting the Emergence of Primary Tillers from the True Leaves of the Main Shoot of a Rice Plant (B. A. C. Enyi), 495

Factors influencing the Radio-Protection of Tissue Culture Cells by Sulphydryl Compounds (A. J. Vergroesen, Miss L. Budke and Prof. J. A. Cohen), 246
Fage, Prof. L. : *Obituary* by Dr. I. Gordon, 1253
Fahmy, Dr. M. J., and Fahmy, Dr. O. G. : Mutagenicity of Ionic Polymers and Leukæmogenic Viruses Relative to Nucleic Acids in *Drosophila melanogaster*, 46
Fahmy, Dr. O. G., and Fahmy, Dr. M. J. : Mutagenicity of Ionic Polymers and Leukæmogenic Viruses Relative to Nucleic Acids in *Drosophila melanogaster*, 46
Falkowski, F., *et al.* : A Second Example of – – –/– – – Blood or Rh$_{null}$, 892
Fall-out in Australia during 1963 : Total Beta Activity in Global, 23
Fall-out, Water and *Unio* Mussels of Lake Maggiore, 1960-63 : Manganese-54 Concentration in (P. Gaglione and Prof. O. Ravera), 1215
Familial Trends of Cancer, 734
Family Planning Association 33rd annual report, 23
Fare, Dr. G. : Partial Protection by an Ox Liver Extract against Rat Liver Carcinogensis by 4-Dimethylaminoazobenzene, 1004
Farnesene in the Natural Coating of Apples : Occurrence of (Dr. K. E. Murray, Dr. F. E. Huelin and J. B. Davenport), 80
Farrar, E., *et al.* : A Simple Mass Spectrometer for the Analysis of Argon at Ultra-high Vacuum, 531
Fast Flux Reversal in Laminated Nickel-Iron Thin Films (Dr. F. B. Humphrey and Dr. H. Clow), 769
Fat Antioxidants : Separation of : Thin-Layer Chromatography on Polyamide Layers (Dr. J. W. Copius-Peereboom), 748
Fat-soluble Vitamins and Biological Membranes (Dr. J. A. Lucy and J. T. Dingle), 156
Fatty Acid Composition of Lipids extracted from Three Spherical Bacteria (Dr. J. P. Brown and Dr. B. J. Cosenza), 802
Fatty Acid Release : Salicylate, a Powerful Inhibitor of Free (A. Bizzi *et al.*), 1205
Fatty Acids : Lipids in the Skin of Mice Deficient in Essential (A. N. Nasr), 1305
Lowering Effect of Neostigmine on Plasma Free (Dr. K. I. Colville *et al.*), 888
"Fatty Acids", seminar, 1258
Fatty Acids of Beef Heart Sphingomyelin (Dr. A. C. Schram, Prof. R. H. Wilson, A. P. Boer and V. E. Doty). 782
Fatty Acids of Rat Adipose Tissue : Effect of Serum from Normal and Diabetic Subjects on Incorporation of Glucose 1-Carbon-14 into Individual (Prof. A. R. Hennes *et al.*), 943
Fatty Liver by Administration of Adenosine Triphosphate : Prevention of (Dr. D. E. Hyams and Prof. K. J. Isselbacher), 1196
Faucett, R., *et al.* : Electron Paramagnetic Resonance in Spinach Chloroplasts at Low Temperature, 1076
Fauna and Flora of the Rivers, Lakes and Reservoirs of the U.S.S.R. (V. I. Zhadin and S. V. Gerd), *review* by D. F. Westlake, 957
Faust, M. A., and Pramer, Prof. D. : Staining Technique for the Examination of Nematode-trapping Fungi, 94
Fawcett, A. S., *et al.* : Water Structure around Silver Iodide Sol Particles, 775
Fawcett, Dr. C. H. : Auxin Activity of Certain Oximes, 1200

Faynot, J. M., and Du Castel, F. : Some Irregularities observed simultaneously in the Upper and Lower Ionosphere at Middle Latitudes, 984
Ferguson, C. W. : Annual Rings in Big Sagebrush *Artemisia tridentata*, *review* by Dr. C. R. Metcalfe, 514
Ferguson, Dr. H. I. S., *et al.* : Laser Excitation of Powdered Solids, 1295
Fergusson, J. D. : Tumours of the Kidney and Ureter, *review*, 1241
Fermi, Enrico, The Professorship of Physics awarded to Prof. T. D. Lee, 827
Ferrite Powders : Microwave Faraday Rotation in (Dr. P. Swarup and N. Kumar), 947
Ferrocene-containing Polymers : Polycondensation of Ferrocene with Aldehydes (E. W. Neuse), 179
Ferrocyanide in Aqueous Solution : Phosphate-mediated Dehydrogenation of Alcohol in the Photochemistry of (Mrs. M. Shirom and Prof. G. Stein), 778
Fertilizer : Urea as a, 230
Feuer, L. S. : The Scientific Intellectual, *review* by G. Buchdahl, 814
Fibre Optics Spectrophotometer for *in vivo* Oximetry (Dr. N. S. Kapany and N. Silbertrust), 138
Fibres Originating in the Visual Cortex : Terminal Distribution in the Superior Colliculus of (R. D. Lund), 1283
Fibrin Clots : Coenzyme Q_6 Derivative from (Prof. P. H. Kopper), 292
Fibrin Clots in Solutions of Heparin : Solubility of (Prof. D. C. Triantaphyllopoulos and Dr. E. Triantaphyllopoulos), 1096
Fibrin formed by Homologous and Heterologous Thrombin : Electrophoretic Patterns of Lysed (Dr. F. Nour-Eldin), 995
Fibrin Monomer during Clotting : Release of Carbohydrate from (A. Rosenberg and R. H. Carman), 994
Fibroblast Line : Collagen and Cell Protein Synthesis by an Established Mammalian (Prof. H. Green and Prof. B. Goldberg), 347
Field Crops : Pests of (F. G. W. Jones and M. G. Jones), *review* by A. H. Strickland, 416
Field Technique for the Concentration of Rainfall within the Individual Seedling Root Range (P. H. Hosegood and P. Howland), 1230
Fielder, Dr. G. : A Case for Convection in the Moon, 171
Figueroa, E., and Pfeifer, A. : Incorporation of ^{14}C-Glucose and ^{14}C-Glucose 6-phosphate into Glycogen and CO_2 by Rat Liver Slices, 576
Filippi, G., *et al.* : Recombination between Protan and Deutan Genes ; Data on their Relative Positions in Respect of the G6PD Locus, 1062
Films in Research and Teaching : Use of, 433
Finch, R. D. : Single Sweep Oscillograph Traces of Sonoluminescence, 770
Findler, N. V. : Machine Learning from Noisy Information, 103
Fine, Dr. B. C., and Molloy, J. O. : Effects of Insecticide Synergists on Duration of Sleep induced in Mice by Barbiturates, 789
Fine Structure of Native Cellulose Microfibrils (Dr. R. St. John Manley), 1155
Fine Structure of Tyloses (R. C. Foster), 494
Finkler, A. E., and Hall, Dr. C. A. : Abnormal Transport of Vitamin B_{12} in Plasma in Chronic Myelogenous Leukæmia, 1207
Finter, N. B. : A Rich Source of Mouse Interferon, 1114
Fischer, D. W., and Baun, W. L. : Influence of Chemical Combination on Aluminium *K* Diagram and Non-diagram Lines, 642
Fischer, Prof. E., *et al.* : Effect of Methylamphetamine on the Psychomotor Depression produced by Adrenaline in Mice, 695
Fischer, W. H., and Perdue, C. R. : Shock-induced Freezing of 'Activated' Supercooled Water, 764
Fish and River Pollution (Dr. J. R. E. Jones), *review* by Dr. J. W. Jones, 1125
Fisher, Dr. P. C., *et al.* : Upper Limit to Jupiter's X-ray Flux on September 30, 1962, 982
Fishes : Genera of Fishes and a Classification of (D. S. Jordan), *review* by Dr. P. H. Greenwood, 7
Recent Reviews of Fossil (Dr. R. J. G. Savage), 735
Fitch, F. J., *et al.* : Age of Caledonian Orogeny and Metamorphism in Britain, 358
Fitzsimons, Dr. J. T. : Drinking caused by Constriction of the Inferior Vena Cava in the Rat, 479
Flaks, A. : Toxicity of Whole Tobacco Tar, 592
Flammarion Book of Astronomy, The, *review* by Patrick Moore, 815
Flanders, Prof. S. E. : Dual Ontogeny of the Male *Coccophagus gurneyi* Comp. (Hymenoptera : Aphelinidae) : A Phenotypic Phenomenon, 944
Fleece Evolution in Domestic Sheep (Dr. M. L. Ryder), 555
Flight, Generalized Hovering, Correlation for Insects (Prof. G. Houghton), 666
Flight Orientation in a Beetle : Nervous Control of (A. J. Burton), 1333
Flora of the Rivers, Lakes and Reservoirs of the U.S.S.R. : Fauna and (V. I. Zhadin and S. V. Gerd), *review* by D. F. Westlake, 957
Florence, Prof. P. S. : Economics and Sociology of Industry, *review* by Prof. T. W. Hutchison, 718
Florey, Sir Howard : The Royal Society, 1129
Florkin, M., and Dollfus, A. (edited by) : Life Sciences and Space Research II, *review* by D. G. King-Hele, 971
Florkin, Prof. M., and Stotz, Prof. E. H. (edited by) : Comprehensive Biochemistry, Vol. 15, *review* by Dr. D. T. Elmore, 219
Flügge, S. (Herausgegeben von) : Handbuch der Physik, Band 27, *review* by Prof. D. R. Bates, 114
Fluid : A General Expression for the Isentropic Stagnation Temperature of a (A. A. R. El Agib), 989
Fluid Circulation in Echinoids : Axial Organ and (Prof. N. Millott and Dr. H. G Vevers), 1216
Fluorescent Brightener for tracing the Passage of *Salmonella* in Eggs : Use of a (Dr. A. M. Paton and Prof. J. C. Ayres), 803
Fluorine : Catalysed Reaction of Xenon with (Dr. B. G. Baker and Dr. P. G. Fox), 466
Fluorine Compounds and Inert Gas Narcosis : Solubility Relations of (R. A. Dawe *et al.*), 789
Fluorobenzene in Aqueous and Other Solutions : Photochemistry and Radiation Chemistry of (Dr. I. Loeff *et al.*), 1300
Fluttering Flight Mechanisms in Insects and Birds (Prof. G. Houghton), 447
Foam Fractionation of Cationic Surfactants : Effect of Inorganic Acids and Bases (Prof. R. B. Grieves and D. Bhattacharyya), 441
Fogle, B. : Noctilucent Clouds in the Southern Hemisphere, 14
Folkers, Dr. K., and Wagner, Dr. A. F. : Vitamins and Coenzymes, *review* by Dr. A. M. Copping, 614
Font, J., *et al.* : Beta-galactosidase of *Helix pomatia*, 686
Fontijn, Dr. A., and Miller, Dr. W. J. : Negative Ion Formation in the Atomic Oxygen-Acetylene Reaction, 679
Food Irradiation Processes with Microbiological Objectives : Tentative Classification of (Dr. H. E. Goresline *et al.*), 237
Food Research : Advances in, Vol. 12 (edited by C. O. Chichester and E. M. Mrak), *review* by Dr. A. M. Copping, 218
Food Research Institute (Agricultural Research Council), Director appointed, 1036
Foot-and-Mouth Disease Virus : Virus Specific Ribonucleic Acids in Baby Hamster Kidney Cells Infected with (Dr. F. Brown and B. Cartwright), 855
Foot-and-Mouth Disease Virus by Guanidine Hydrochloride : Inhibition of Multiplication of (Dr. C. R. Pringle), 1012
Foraminifera between the Sarns, Cardigan Bay : Live and Dead (Dr. J Haynes), 774
Forbidden Lines from Atomic Sulphur (Dr. J. W. McConkey, D. J. Burns, Prof. L. Herman), 1180
Force associated with the Temperature Gradient on a Small Particle suspended in a Plasma (J. R. Brock), 69
Forest Fire Control : Soviet Progress in (edited by N. P. Kurbatskii), *review* by Dr. C. J. Taylor, 957
Formation of Isorhodopsin in the Frog's Eye during Continuous Illumination (T. Reuter), 784
Formation and Decomposition of Alkaline 'Pernitrite' (Dr. H. M. Papée and Dr. G. L. Petriconi), 142
Formazan Reaction as a Confirmatory Test for Aldehyde Groups in Histochemistry (Dr. P. J. Stoward and Dr. L. Mester), 488
Formwork for Concrete : Glued, 1139
Forsyth, F. R., and Lockhart, C. L. : Influence of Fungicides on the Tomato and Growth of *Botrytis cinerea* Pers, 1107
Forward Scattering of Light from a Laboratory Plasma (U. Ascoli-Bartoli, J. Katzenstein and L. Lovisetto), 672
Foskett, D. J. : Science, Humanism and Libraries, *review* by R. Brightman, 417
Fossil Diptera and Continental Drift (Dr. D. H. Colless), 402
Fossil Fishes : Recent Reviews of (Dr. R. J. G. Savage), 735
Fossil Plants of the Carboniferous Rocks of Great Britain (Second Section), 1257
Fossils in the Much Quartzite : Graptolites from the Kashmir Himalayas, also a Note on the Discovery of (Prof. M. R. Sahni and V. J. Gupta), 1081
Foster, R. C. : Fine Structure of Tyloses, 494
Fowler, Dr. P. H., appointed to a Royal Society Research Professorship, 630
Fox, Dr. P. G., and Baker, Dr. B. G. : Catalyzed Reaction of Xenon with Fluorine, 466
Fox, R. H., *et al.* : Isolation of a Highly Purified Encephalitogenic Protein from Bovine Cord, 1273
Fox-Williams, Capt. J. : Handbook of Industrial Electroplating, third edition, *review*, 816
Foy, Dr. H., and Kondi, A. : Reticulo-endothelial Cells as 'Nurses' for Plasma Cells and Erythroblasts in Baboons, 293
Fracture Healing : Serum Calcium and Phosphorus in Rabbits during, with Reference to Parathyroid Activity (Dr. F. A. Soliman and S. Y. S. Hassan), 693
Fram, Dr. D. H., *et al.* : Methylhistamine and Histamine in the Urine of Women during the Elaboration of Œstrogen, 1165
France : *The State and Education in France*, 524
Franck-Condon Factors : Interpolation of (Prof. R. W. Nicholls), 373
Frankel, Dr. J. W. : Neutralizing Antibody Responses of Guinea-Pigs to Inactivated Rubella Virus Vaccine, 655
Frankenhaeuser, Dr. B. : The Conduction of the Nervous Impulse, *review*, 1238
Franks, Rt. Hon. Lord : British Institute of Management, *British Business Schools*, 611
Frazer, M. J., and Gerrard, Dr. W. : Significance of the Solubility of Hydrogen Halides in Mercaptans and Thioethers, 1299
Free Radicals : Chlorine Hyperfine Splittings in Phenoxy (B. T. Allen and W. Vanneste), 991
Free Radicals in Flash Photolysis : Identification of (Dr. G. Herzberg and Dr. D. N. Travis), 988 ; (Dr. W. D. McGrath and T. Morrow), 988
Freezing : Melting and (Prof. A. R. Ubbelohde), 1046
Freezing of 'Activated' Supercooled Water : Shock-induced (W. H. Fischer and C. R. Perdue), 764
Freinkel, Prof. N., and Scott, T. W. : Effect of Pituitary Thyrotrophin on the Diglyceride/Triglyceride Interrelationships in Thyroid Tissue, 1313
Freudenthal, A. M., *et al.* (edited by) : High Temperature Structures and Materials : Proceedings of the Third Symposium on Naval Structural Mechanics, 1963, *review* by Prof. A. J. Kennedy, 414
Freundlich, Prof. E. F. : *Obituary* by Prof. Z. Kopal, 727
Frick, M. : On a Possibility of measuring the Einstein-shift Photoelectrically, 1076
Friends of the Lake District : *Traffic in the Lake District*, 508
Frog Muscle : Volume Change accompanying Passive Stretch of (Prof. R. J. Baskin and P. Paolini), 694

Frog's Eye during Continuous Illumination : Formation of Isorhodopsin in the (T. Reuter), 784
Frost-resistant Insect : A Large Amount of Trehalose in a (E. Asahina and K. Tanno), 1222
Frozen Aqueous Systems at 77°K : Reversible Photochemical Bleaching in (P. N. Moorthy and Prof. J. J. Weiss), 776
Frozen Rocks : An Introduction to the Theory of the Formation of (I. A. Tyutyunov), *review* by Dr. E. I. Hamilton, 816
Fruit Bodies of *Coprinus lagopus* sensu Buller : Recovery of Monokaryons from Veil Cells of (J. W. Cowan), 1113
Fruit Proanthocyanidins : Presence of Several Phenolic Components in (S. Ito and Prof. M. A. Joslyn), 475
Fruits and Vegetables : Phenolics in Normal and Diseased (Dr. M. K. Seikel), 337
Frumento, Dr. A. S., and Mullins, Dr. L. J. : Potassium-free Effect in Squid Axons, 1312
Fuchs, N. A. : The Mechanics of Aerosols, *review* by J. F. Croft, 1236
Fucose-containing, Trisaccharide from Human Blood-group Lea Substance Isolation of a Serologically Active, (V. P. Rege *et al.*), 740
Fujimori, E. : Modified Phycoerythrin from *Porphyridium cruentum* treated with *p*-Chloro-mercuribenzoate, 1091
Fukuda, Prof. T., *et al.* : Development of Shock-inducing Factor in Canine Endotoxin Shock, 585
Fukuda, Prof. T., and Murata, K. : Hepatic Pyrogen and Cortisone-antipyresis in Canine Endotoxin Fever, 690
Fukuma, A., *et al.* : Anthropological Observations of Blood Groups in Hiroshima, 87
Fuller, Dr. A. T. : The Mathematical Theory of Optimal Processes, *review*, 1124
Fumarate to Succinate in Yeast : Mitochondrial and Cytoplasmic Enzymes for the Reduction of (Dr. C. Rossi *et al.*), 167
Funakoshi, H., and Matuura, R. : Peptizing Action of Some Polar Substances on the Benzene Solution of Cobalt Oleate, 186
Fundamental Particles (K. Nishijima), *review* by Dr. R. G. Moorhouse, 979
Fungal Infection on the Production of Ethylene by Carnations : Effect of Damage and (W. H. Smith, Dr. D. F. Meigh and J. C. Parker), 92
Fungi : Antibiotic-producing Microscopic (V. I. Bilai), *review* by Dr. R. W. G. Dennis, 8
Staining Technique for the Examination of Nematode-trapping (M. A. Faust and Prof. D. Pramer), 94
Fungi in the Rhizosphere : Occurrence of Nematode-trapping (E. A. Peterson and H. Katznelson), 1111
Fungicide : Influence of Excreted Substance from Leaves on Decomposition of Zineb, a Dithiocarbamate (Prof. A. Kovàcs and N. J. A. Cucchi), 1090
Fungicides on the Tomato and Growth of *Botrytis cinerea* Pers. : Influence of (C. L. Lockhart and F. R. Forsyth), 1107
Fungus : Histological Reactions of *Bufo melanostictus* to Culture Filtrates and Mycelial Extracts of a Pathogenic (Dr. S. S. Dhaliwal and Dr. D. A. Griffiths), 345
Funnell, Dr. B. M., and Harrison, Dr. C. G. A. : Relationship of Palæomagnetic Reversals and Micropalæontology in Two Late Cænozoic Cores from the Pacific Ocean, 566
Furniture Development Council, fifteenth annual report, 128
Future of Botany (Prof. R. D. Preston), 12

Gaglione, P., and Ravera, Prof. O. : Manganese-54 Concentration in Fall-out, Water, and *Unio* Mussels of Lake Maggiore, 1960-63, 1215
35-Gc/s, 70-Gc/s and 94-Gc/s Cytherean Radiation (Prof. C. W. Tolbert and Prof. A. W. Straiton), 1242
Gajdusek, Dr. D. C., and Gibbs, jun., Dr. C. J. : Attempts to Demonstrate a Transmissible Agent in Kuru, Amyotrophic Lateral Sclerosis, and other Sub-acute and Chronic Nervous System Degenerations of Man, 257
Galactic Centre : Distribution and Motions of OH near the (J. G. Bolton *et al.*), 30
Galactic Centre Region : Microwave Observations of the (Dr. A. Maxwell and Dr. D. Downes), 865
Galactic Radio Emissions : Spectra of the (Prof. G. R. A. Ellis), 171
Galactose-6-phosphate : Enzymatic Oxidation of (T. Inouye *et al.*), 1304
Beta-galactosidase of *Helix pomatia* (R. Got, A. Marnay, P. Jarrige and J. Font), 686
Galapagos Tortoise and Marine Iguana Deep Body Temperatures measured by Radio Telemetry (Prof. R. S. Mackay), 355
Galaxy : Absorption of Radio Waves in the (Prof. G. R. A. Ellis and P. A. Hamilton), 272
Galbraith, Prof. J. K. : Economic Development, *review* by R. Brightman, 1024
Gallagher, Dr. C. H., *et al.* : Toxicity of *Phalaris tuberosa* for Sheep, 542
Gametophytic Plants induced from Single Cells of Moss Callus (M. Ward), 400
Gamkrelidze, R. V., *et al.* : The Mathematical Theory of Optimal Processes, *review* by Dr. A. T. Fuller, 1124
Gamma-emitters in a Fin Whale (Prof. C. Osterberg, W. Pearcy and N. Kujala), 1006
Gamma-globulin Allotypes : Rabbit (U. Grodecka), 595
Gamma-irradiation : Early Response of *Pinus thunbergii* to Acute (J. P. OKunewick *et al.*), 394
Gamma-radiation emitted during Proton Bombardment : Determination of Carbon in Steels by Measurement of the Prompt (T. B. Pierce *et al.*), 571
Gamma-rays : Detection of an Interstellar Flux of (Dr. A. E. Metzger *et al.*), 766
Gamma-rays in *Allium cepa* : Aminothioamides as Protectors against the Effect of (Dr. M. D. El Khalifa), 708
d-Gamma-tocopherol on the Incidence of Teratogeny in Vitamin E-deficient Rats : Effect of (Prof. D. W. King), 785
Gammack, Dr. D. B., *et al.* : Lipid-Protein Unit in Myelin, 553
Type of Antibody Response in Mice immunised with Transplantable Tumours, 391
Garattini, Prof. S., *et al.* : Salicylate, a Powerful Inhibitor of Free Fatty Acid Release, 1205
Gardner, D. L., *et al.* : Human Histology, *review* by E. H. Leach, 977
Gardner, F. F., *et al.* : Distribution and Motions of OH near the Galactic Centre, 30
Gardner, H. J. : Brown (β) Titanium Trichloride, 282
Garner, Prof. F. H., *Obituary* by Prof. J. T. Davies, 626
Garrett-Jones, D. : Prognosis for Interruption of Malaria Transmission through Assessment of the Mosquito's Vectorial Capacity, 1173
Garten, V. A., and Head, R. B. : Hydrogen-bonding Patterns and Ice Nucleation, 573
Gas Reactions : Experimental Methods in, second edition, (Sir Harry Melville and B. G. Gowenlock), *review* by D. H. Desty, 965
Gaseous Nitrogen changes in the Soil : Plant : Atmosphere System : A Gas-tight Growth Chamber for Investigating (P. J. Ross *et al.*), 444
Gas-tight Growth Chamber for Investigating Gaseous Nitrogen Changes in the Soil : Plant : Atmosphere System (P. J. Ross, Dr. A. E. Martin and Dr. E. F. Henzell), 444
Gastrin, The Antral Hormone : (Dr. H. Gregory *et al.*), 931
Gavin, J., *et al.* : Blood Group Antigen Xg^a in Gibbons, 1322
Xg Blood Groups of Chinese, 1002
Gay, Prof. H., *et al.* : Autoradiographic Evidence of Synthesis of an Arginine-rich Histone during Spermiogenesis in *Drosophila melanogaster*, 1008
Geake, Dr. J. E. : Lunar Luminescence, 855
Gemmæ of *Marchantia polymorpha* : Relationship between Nuclear Volume and Radiosensitivity of Different Cell Types in (M. W. Miller and Dr. A. H Sparrow), 596
Gemmell, Dr. M. A. : Species Specificity of the Immunogenic Complexes of the Tapeworm Hexacanth Embryo, 705
Gemser-Runia, J., and Nijenhuis, Dr. L. E. : Xg^a Investigations of the Family of a Child with a Ring X Chromosome, 792
Genera of Fishes and a Classification of Fishes (D. S. Jordan), *review* by Dr. P. H. Greenwood, 7
General Post Office : Retirement and Appointment of Director, 728
"General Relativity and Gravitation", international conference, 24
Generalization of Epidemic Theory (Dr. W. Goffman and Dr. V. A. Newill), 225
Generation of Giant Pulses from a Neodymium Laser by a Reversibly Bleachable Absorber (B. H. Soffer and Dr. R. H. Hoskins), 276
Genes : Recombination between Protan and Deutan : Data on their Relative Positions in Respect of the G6PD Locus (M. Siniscalco *et al.*), 1062
Genes on Chromosomes : A New Theory to Explain Crossing-over between (Prof. C. C. Lindegren), 322
Genesis and Biogenesis of Ethylene (Dr. M. Lieberman and Dr. L. W. Mapson), 343
Genetic Assimilation of Behaviour in *Drosophila melanogaster* : Confirmation of apparent (P. Arnold and Dr. N. Moray), 504
Genetic Morphism : Schizophrenia as a (Sir Julian Huxley *et al.*), 220
Genetic Type of the Source Material for Common Leads (A. Masuda), 373
Genetic Variation of Alcohol Dehydrogenase in *Drosophila melanogaster* (F. M. Johnson and C. Denniston), 906
Genetical Research in an Area of High Natural Radioactivity in South India (Prof. H. Grüneberg), 222
Genetically Controlled Variation in Pteridine Content of *Pieris brassicae* L. (Dr. R. Harmsen), 1111
Genetics of Bacteria and their Viruses (Dr. W. Hayes), *review* by Dr. B. A. D. Stocker, 6
Genetics of Plasmids in *Salmonella typhimurium* (Mrs. E. Dubnau and Prof. B. A. D. Stocker), 1112
Genetics and Breeding of Rice (Prof. M. F. Chandraratna), *review* by Dr. E. H. Roberts, 217
Genitalia of the Australian Earwig, *Labidura riparia truncata* (Dermaptera : Labiduridae). : Independent Development of the Male Gonads and Vasa Deferentia, and the (Dr. E. T. Giles), 1109
Gent, Dr. W. L. G., *et al.* : Lipid-Protein Unit in Myelin, 553
Geo-Botanical Surveying : Short Guide to (S. V. Viktorov *et al.*), *review* by W. D. Clayton, 419
Geographers and the Tropics (edited by Robert W. Steel and R. M. Prothero), *review* by Prof. L. Dudley Stamp, 510
Geological Structures : Kink-bands and Related (B. Marshall), 772 ; (Dr. T. B. Anderson), 772
Geological Survey of Great Britain and the Museum of Practical Geology, 730
Geology of British Guiana : A New Interpretation of the (Dr. R. B. McConnell, Dr. E. Williams, Dr. R. T. Cannon and Dr. N. J. Snelling), 115
Geometrical Rearrangement of Aggregated Chlorophyll *in vivo* during the Greening Process (Dr. S. S. Brody), 470
Gerd, S. V., and Zhadin, V. I. : Fauna and Flora of the Rivers, Lakes and Reservoirs of the U.S.S.R., *review* by D. F. Westlake, 957
Gerhardt, Prof. P., and Scherrer, Dr. R. : Molecular Sieving by Cell Membranes of *Bacillus megaterium*, 649
Germplasm : The Architecture of the (Prof. V. Grant), *review* by Dr. H. K. Whitehouse, 978
Gerold, J. L., and Laarman, J. J. : Selection of some Strains of *Anopheles atroparvus* with Different Behavioural Responses to Contacts with DDT, 500
Gerrard, Dr. W. : Synthesis of Organosilicon Monomers, *review*, 512, 830
Gerrard, Dr. W., and Frazer, M. J. : Significance of the Solubility of Hydrogen Halides in Mercaptans and Thioethers, 1299
Gerrard, Dr. W., and Hudson, Dr. H. R. : Carbonium Ion Mechanism and Results of Solvolysis of (+)-2-Bromo-octane, 876
Gershanovitch, V. N., *et al.* : Sphæroplasts of E. coli obtained by the Lytic Enzyme isolated from Phage T_2, 1331
Gershenson, D. E., and Greenberg, D. A. : Anaxagoras and the Birth of Physics, *review* by Mrs. M. B. Hall, 968
Anaxagoras and the Birth of Scientific Method, *review* by Mrs. M. B. Hall, 968
Ghiselli, Prof. E. E., and Brown, Prof. C. W. : Personnel and Industrial Psychology second edition, *review* by Dr. W. L. Sumner, 418
Ghose, Dr. T., and Tso, S. C. : Uptake of Protein by Regenerating Liver Cells, 1210
Giacconi, Prof. R., *et al.* : Two Sources of Cosmic X-rays in Scorpius and Sagittarius, 981
Gibberellic Acid on the Growth and Multiplication of Some Soil Micro-organisms and Unicellular Green Algae : Effect of (S. Saono), 1328
Gibberellin-like Substances in Peanut (*Arachis hypogaea*) : Auxin and (A. Gordin-Sharir and Prof. P. F. Wareing), 1308
Gibberellin Production by Plant Organs : Agar diffusion Technique for estimating (R. L. Jones and Dr. I. D. J. Phillips), 497
Gibbons : Blood Group Antigen Xg^a in (J. Gavin *et al.*), 1322
Gibbs, jun., Dr. C. J., and Gajdusek, Dr. D. C. : Attempts to Demonstrate a Transmissible Agent in Kuru, Amyotrophic Lateral Sclerosis, and other Sub-acute and Chronic Nervous System Degenerations of Man, 257
Gibbs, Dr. W. J. : Tensors in Electrical Engineering, *review*, 112
Gibbsite in Altered Granitic Rock in North Wales (D. F. Ball), 673
Gibson, Prof. A. F., and Burgess, Prof. R. E. (edited by) : Progress in Semiconductors, Vol. 8, *review* by Dr. B. Donovan, 513
Gibson, F. C., and Watson, R. W. : Jets from Imploding Bubbles, 1296
Giddings, Prof. J. L. : The Archæology of Cape Denbigh, *review* by M. C. Burkitt, 1125
Giles, Dr. E. T. : Independent Development of the Male Gonads and Vasa Deferentia, and the Genitalia of the Australian Earwig, *Labidura riparia truncata* (Dermaptera : Labiduridae), 1109
Gilman, J. P. W., and Basrur, P. K. : Blood Culture Method for the Study of Bovine Chromosomes, 1335
Giok, P-O. H., and Eng, Dr. L-I. L. : Glucose-6-phosphate Dehydrogenase Deficiency in Indonesia, 88
Giron, Dr. D. J., and Heliman, Dr. A. : Purification of Poliovirus by DEAE 'Sephadex A-25', 263
Glaser, P. E., and Salisbury, J. W. (edited by) : Lunar Surface Layer, *review* by Prof. Z. Kopal, 974
Glasgow University Exploration Society Expedition to Mingulay (J. F. Robertson, J. B. Rankin, Dr. D. R. Bowes and A. M. Hopgood), 25
Glasshouse Soils : Simple Estimation of Soluble Salts in (D. J. Eagle), 1227
Glass Surfaces : Interaction of Phosphorus-32 and Carbon-14-labelled Tritolyphosphate with (Dr. M. E. Schrader and I. Lerner), 759
Glazebrook, G. W., *et al.* : Simple Separation of Rabbit Marrow Myeloid Cells from Erythroid Cells, 996
Glen, Dr. R., awarded the Canadian Entomological Society's Gold Medal, 1038

Glial Multiplication in the Adult Rat Brain : Autoradiographic Examination of the Effects of Enriched Environment on the Rate of (Prof. J. Altman and G. D. Das), 1161
Gliotoxin and Gliotoxin Acetate : Antiviral Activity of (Dr. W. A. Rightsel *et al.*), 1333
7 S Globulin Immunologically Identical to 19 S gamma-1 (beta-2)-*M*-globulin, a New Protein of Horse Serum (Dr. G. Sandor, S. Korach and P. Mattern), 795
Glossina morsitans : Effect of Two Chemosterilants on (P. R. Chadwick), 299
Glowacki, E. R., and Millette, R. L. : *In vivo* Maturation of Immature Reticulocytes transfused into a Normal Rabbit, 1207
Glowinski, Dr. J., and Axelrod, Dr. J. : Inhibition of Uptake of Tritiated-noradrenaline in the Intact Rat Brain by Imipramine and Structurally Related Compounds, 1318
α-D-Glucosamine, L-Glucose and D-Xylose : First Receptor in Intestinal Sugar Transport : the Effect of Phloridzin and of Cetrimide on the Intestinal Absorption of (S. L. Hart and Dr. J. A. Nissim), 51
Glucose 1-Carbon-14 into Individual Fatty Acids of Rat Adipose Tissue : Effect of Serum from Normal and Diabetic Subjects on Incorporation of (Prof. A. R. Hennes *et al.*), 943
Glucose-6-phosphate Dehydrogenase Deficiency in Indonesia (Dr. L-I. Luan Eng and P-O. H. Giok), 88
Glucose-6-phosphate Dehydrogenase Deficiency in Malayan Aborigines : Abnormal Hæmoglobin and (Dr. L-I. L. Eng and J. Chin), 291
^{14}C-Glucose and ^{14}C-Glucose 6-phosphate into Glycogen and CO_2 by Rat Liver Slices : Incorporation of (H. Figueroa and A. Pfeifer), 576
L-Glucose and D-Xylose : First Receptor in Intestinal Sugar Transport : the Effect of Phloridzin and of Cetrimide on the Intestinal Absorption of α-D-Glucosamine, (S. L. Hart and Dr. J. A. Nissim), 51
Glued Formwork for Concrete, 1139
Glutathione and Serotonin of Mice against Whole-body Irradiation : Protection with 2-β-Aminoethylisothiourea, (Dr. J. R. Maisin), 196
Glyceraldehyde-3-Phosphate Dehydrogenase : Structure of (Dr. H. C. Watson and Dr. L. J. Banaszak), 918
Glycerol Medium : Pigment Formation by *Acetobacter acetigenum* in a Lactate-buffered (Prof. K. Ramamurti and C. P. Jackson), 402
Glycogen and CO_2 by Rat Liver Slices : Incorporation of ^{14}C-Glucose and ^{14}C-Glucose 6-phosphate into (H. Figueroa and A. Pfeifer), 576
Glycogen-levels in the Isolated Rat Liver : Failure of Physiological Concentrations of Epinephrine to affect (Prof. J. E. Sokal and Dr. E. J. Sarcione), 881
Glycogen Synthesis : Mechanisms of Regulation of Hepatic (Prof. D. F. Steiner), 1171
Glycolysis in Ciliary Body : Inhibition of Ouabain of (Dr. M. V. Riley), 380
Glycolysis and Respiration of Transformed *BHK21* Cells (M. Broadfoot, P. Walker, Dr. J. Paul, Dr I. Macpherson and Prof. M. Stoker), 79

Heterozygous for Different Rare Abnormal Hæmoglobins : Oxygen Equilibria of Red Cell Hæmolysates of Adult Individuals, (Prof. T. H. J. Huisman and J. M. Achillhorn van Veen), 701
Hevea brasiliensis : Boron Toxicity in (Dr. V. M. Shorrocks), 599
Hewer, H. R. : Seals of the World, *review*, 978
Hexacanth Embryo : Species Specificity of the Immunogenic Complexes of the Tapeworm (Dr. M. A. Gemmell), 705
Hexammine Nickel Chloride : Annealing Behaviour of Recoil Cobalt-57 Atoms in (K. Yoshihara), 1296
Heymann, Dr. D. : Origin of the Canyon Diablo No. 2 and No. 3 Meteorites, 819
Heyn, C. C. : Annual Species of *Medicago*, *review* by R. D. Meikle, 316
Heywood, Dr. H. : Solar Radiation on Inclined Surfaces, 669
Standard Date Periods with Declination Limits, 768
Hibbitt, Dr. K. G. : Levels of Coenzyme *A* in the Liver of Normal Cows and of Cows suffering from Primary Ketosis, 206
Hibernating Mammals : Uptake of Potassium at Low Temperatures in Kidney Cortex Slices of (Prof. J. S. Willis), 691
High Energy Nuclear Physics : Why Should We Study (Prof. C. F. Powell), 421
High-intensity Flash Discharge as a Source of Radiant Energy for Sterilizing Insects (D. F. Riordan), 1332
High-pressure Polymorph of Zirconium Pyrophosphate (Dr. C. B. Sclar, L. C. Carrison and Dr. C. M. Schwartz), 573
High Temperature Dyeing, 1260
High Temperature in *Rhodnius prolixus* (Stal.) : Effects of (A. Y. K. Okasha), 1221
High Temperature Structures and Materials : Proceedings of the Third Symposium on Naval Structural Mechanics, 1963 (edited by A. M. Freudenthal, B. A. Boley and H. Liebowitz), *review* by Prof. A. J. Kennedy, 414
Higher Education in Britain, 22
Hilgert, Dr. I., *et al.* : Role of Debris of Tumour Ascitic Fluid in Transplantation Immunity, 704
Hill, Prof. A. V. : *Obituary* of Dr. L. E. Bayliss, 327
Hill, Dr. R. M. : Electrical Conduction in Thin Aggregated Metal Films, 35
Hinshelwood, Sir Cyril : The Chemical Origin of Life, *review*, 949
Hiorth, G. E. : Quantitative Genetik, *review* by Prof. W. Williams, 614
Hiroshima : Anthropological Observations of Blood Groups in (T. Tsuchiya *et al.*), 87
Hirst, Dr. D. M., *et al.* : Iron-deficient Low-temperature Pyrrhotite, 175
Hirst, Sir Edmund : Awarded the Gunning Victoria Jubilee Prize, 1258
Histaminase Activity : Rapid Spectrophotometric Micromethod for Determination of (P. N. Aarsen and A. Kemp), 1195
Histamine in the Urine of Women during the Elaboration of Œstrogen : Methylhistamine and (Prof. J. P. Green *et al.*), 1165
Histidine of the Inhibition of *Prototheca* Growth due to 3-Amino-1,2,4-triazole : Reversal by (Dr. P. J. Casselton), 93
Histochemical Evidence on Localization of Succinic Dehydrogenase in the Synapse of the Central Nervous System of Rabbit, Rat and Guinea-pig : (Dr. T. Kumamoto and Prof. G. H. Bourne), 295
Histochemical Reactions used to detect Cholinesterase in Muscle : Electron-microscopical Localization of Products from (Dr. R. Miledi), 293
Histochemistry : Formazan Reaction as a Confirmatory Test for Aldehyde Groups in (Dr. P. J. Stoward and Dr. L. Mester), 488
Histological Reactions of *Bufo melanostictus* to Culture Filtrates and Mycelial Extracts of a Pathogenic Fungus (Dr. S. S. Dhaliwal and Dr. D. A. Griffiths), 345
Histone in these Protozoa : Antigenicity of Trypanosome Nuclei : Evidence that DNA is not coupled to (Dr. J. S. Beck and Dr. P. J. Walker), 194
Histones on Embryonic Development : Effects of (Prof. J. Brachet), 1218
Histones and Deoxyribonucleic Acid : Specificity of the Interactions between (E. W. Johns and Prof. J. A. V. Butler), 853
History of Chemistry, Vol. 4 (Prof. J. R. Partington), *review* by Prof. A. R. Hall, 967
History of Woodworking Tools (W. L. Goodman), *review* by Miss Joan Liversidge, 314
Histotopochemistry of Ascorbic Acid in Tendon Fibres (Dr. F. Bartoš), 1104
Hoare, Dr. J. P. : Some Double-layer Capacity Measurements on Platinum Electrodes, 71
Hodges, Dr. J. R., *et al.* : Effect of Electroconvulsive Therapy on Plasma Corisol-levels, 754
Hodgkin, Prof. A. L. : The Conduction of the Nervous Impulse, *review* by Dr. B. Frankenhauser, 1238
Hodgkin, Prof. D. C. : Awarded the Nobel Prize for Chemistry, 922
Hodgson, Dr. E., *et al.* : Metabolism of Nicotine by Tobacco-feeding Insects, 300
Hodgson, P. E. : The Optical Model of Elastic Scattering, *review* by Dr. J. E. Evans, 211
Hoedemaker, Dr. F. S., *et al.* : Dream Deprivation : an Experimental Reappraisal, 1337
Hoffer, Prof. A., *et al.* : Schizophrenia as a Genetic Morphism, 220
Hofmann, J. E., *et al.* : Autoxidation of Carbanions in Azoxybenzene, 376
Hogg, J. F. : L'Électronique dans les Appareils de Contrôle Nucléaire, Tome I, *review*, 8
Holdgate, Dr. M. W. : Pacific Basin Biogeography, a Symposium, *review*, 1236
Holford, Sir William : Architecture, Technology and South Kensington, 616
Holly, Prof. R. G., *et al.* : Lysozyme Content of Human Milk, 76
Holzer, T., *et al.* : Electron Paramagnetic Resonance in Spinach Chloroplasts at Low Temperature, 1076
Hominid Phylogeny : A Comparison between the Olduvai Hominines and those of Java and some Implications for (Prof. P. V. Tobias and Prof. G. H. R. von Koenigswald), 515
Homografts of Neonatal Lung Tissue in Mice : Effect of Cigarette-smoke Condensates on (Dr. J. A. DiPaolo), 1159
Homologous Cells in Tissue Culture by Nuclei of Immune Lymphocytes : Destruction of (Dr. G. J. Svet-Moldavsky and I. J. Chernyakhovskaya), 799
Homology and Analogy : Paralogy, a Concept Complementary to (I. J. Hunter), 604
Homopolar Generator : Tests with Solid Brushes on the Canberra (Dr. R. A. Marshall), 1079
Homovanillic Acid in the Human Brain : Distribution of (Dr. H. Bernheimer), 587
Homozygous Gunn Rat : Serum Enzymes in the Jaundiced (Dr. T. Hargreaves and B. Thom), 1323
Hooke and 'Boyle's Law' : Newton, (Prof. I. B. Cohen), 618
Hop (*Humulus lupulus* L.) : Occurrence and Dispersal of *Verticillium* Conidia in Xylem Sap of the (Dr. G. W. F. Sewell and J. F. Wilson), 901
Hopf, H. C., *et al.* : Trigeminus Reflex in Young Infants, 1312
Hopgood, A. M., *et al.* : The Glasgow University Exploration Society Expedition to Mingulay, 25
Hopkins, C. R., and King, Dr. P. E. : Occurrence of Microvilli and Micropinocytosis in Trophocyte of *Bombus*, 298
Hopkinson, D. A., *et al.* : Phosphoglucomutase Polymorphism in Man, 742
Hopton, Dr. J. W., *et al.* : Degradation of Type XIV *Pneumococcus* Polysaccharide by Induced Enzymes, 938
Hordeum vulgaris Seedlings : Catalase Activity of a Crude Enzyme Preparation from Iron-chlorotic Barley (S. Kotaka *et al.*), 1198
Hormonal Effects as a Result of Chronic Morphinization : Reversal of (Prof. E O'F Walsh, C. H. Lee Peng and M. L. Ng), 698
Horridge, Dr. G. A. : Multimodal Interneurones of Locust Optic Lobe, 499
Horse Serum : 7 *S* Globulin, Immunologically Identical to 19 *S* Gamma-1 (beta-2)-*M*-globulin, a New Protein of (Dr. G. Sandor *et al.*), 795
Horsler, A. F. C., and Baxter, B. H. : Isotope Effects in the Infra-red Spectra of some Carbon-14-labelled Acids, an Ester and Sodium Salt, 675
Horton, Dr. E., *et al.* : Development of Ribonucleic Acid Polymerase in Cells Infected with Encephalomyocarditis Virus and the Synthesis of Single- and Double-stranded RNA by the Isolated Polymerase, 247
Horwood-Barrett, S., *et al.* : Rapid Induction by Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin, 1316

Hsia, Prof. D. Y., *et al.* : Enzymatic Oxidation of Galactose-6-phosphate, 1304
Hudson, Dr. H. R., and Gerrard, Dr. W. : Carbonium Ion Mechanism and Results of Solvolysis of (+)-2-Bromo-octane, 876
Huelin, Dr. F. E., *et al.* : Occurrence of Farnesene in the Natural Coating of Apples, 80
Hufschmidt, H. J., *et al.* : Trigeminus Reflex in Young Infants, 1312
Hughes Medal awarded to Prof. A. Salam, 728, 1130
Hughes, T. P., and Archbold, E. : Electron Temperature in a Laser-heated Plasma, 670
Hughes, W. G. : Torques and Attitude Sensing in Earth Satellites, *review*, 973
Huisman, Prof. T. H. J., and Schillhorn van Veen, J. M. : Oxygen Equilibria of Red Cell Hæmolysates of Adult Individuals, Heterozygous for Different Rare Abnormal Hæmoglobins, 701
Hulliger, Dr. F. : Crystal Structure and Electrical Properties of some Cobalt-group Chalcogenides, 644
New Representatives of the $NbAs_2$ and $ZrAs_2$ Structures, 775
$TiAs_2$-type Phases, 991
Human Biology (G. A. Harrison, J. S. Weiner, J. M. Tanner and N. A. Barnicot), *review* by Sir Julian Huxley, 950 ; *erratum*, 1141
Human Histology (B. Cruickshank, T. C. Dodds and D. L. Gardner), *review* by E. H. Leach, 977
"Human Palaeopathology", symposium on, 1141
Human Tumours Secreting Catecholamines (Prof. H. Hermann and Prof. R. Mornex), *review* by Dr. A. B. Anderson, 613
Humic Acids : Oxidation-reduction Potentials and Capillary Activities of (Dr. S. A. Visser), 581
Humphrey, Dr. F. B., and Clow, Dr. H. : Fast Flux Reversal in Laminated Nickel-Iron Thin Films, 769
Humphries, Dr. E. C. : The John Innes Institute, 232
Régulateurs Naturels de la Croissance Végétale, *review*, 1240
Hunt, J. C., *et al.* : Plasma Angiotensinase Activity in Human Hypertension, 1096
Hunter, I. J. : Paralogy, a Concept Complementary to Homology and Analogy, 604
Hunter, jun., Prof. O. B., *et al.* : A Second Example of ---/--- Blood or Rhnull, 892
Huntsman, R. G., *et al.* : A New Hæmoglobin — J_a Oxford Found during a Survey of an English Population, 269
Hurricane Development : Tidal Components in (D. A. Bradley), 136
Husain, S. R., and Burlin, Dr. T. E. : Electron Transfer in Irradiated Vacuum Cavity Chambers, 563
Measurement of the Emission of Low-energy Electrons in an Irradiated Vacuum Cavity Chamber, 1078
Saturation Characteristics of a Spherical Ionization Chamber and a Determination of Boag's Constant for Air, 670
Hutchison, Prof. T. W. : Economics and Sociology of Industry, *review*, 718
Hutt, C., *et al.* : Arousal and Childhood Autism, 908
Hutt, S. J., *et al.* : Arousal and Childhood Autism, 908
Hutten, Dr. E. H. : The Act of Creation, *review*, 975
Huxley, Sir Julian : Human Biology, *review*, 950 ; *erratum*, 1141
Huxley, Sir Julian, *et al.* : Schizophrenia as a Genetic Morphism, 220
Hyams, Dr. D. E., and Isselbacher, Prof. K. J. : Prevention of Fatty Liver by Administration of Adenosine Triphosphate, 1196
Hydatid Disease in New Zealand, 629
Hyde, F. W., *et al.* : Spaced-site Observations of Jupiter in 1963, 637
Hyderabad : M_2 Component at (Dr. S. Balakrishna and B. R. Lakshmi), 774
Hydra : Some Biological and Biochemical Properties of the Polarizing Factor in (G. E. Lesh and A. L. Burnett), 492
Hydration of Calcium Sulphate Hemihydrate (M. J. Ridge), 70
bis-Hydrazides and Related Compounds, 430
Hydrocarbon : Possible Mechanism for the Extra-terrestrial Synthesis of Straight chain (Dr. C. B. Johnson and Prof. A. T. Wilson), 181
Hydrocyanic Acid Content and Nitrogen-fixing Capacity of Guar (Dr. O. L. Oke), 405
Hydrogen Atoms in Irradiated Ethanol : Iodine as a Scavenger for (N. T. Barker and Prof. J. H. Green), 872
Hydrogen Bond in Phenols : Proton Magnetic Resonance of the (Dr. G. Pala), 1190

Hydrogen Bonding Patterns and Ice Nucleation (V. A. Garten and R. B. Head), 573
Hydrogen Halides in Mercaptans and Thioethers : Significance of the Solubility of (M. J. Frazer and Dr. W. Gerrard), 1299
Hydrogen on Hydrogen-Montmorillonite : Bonding of (Prof. I. Th. Rosenqvist and P. Jørgensen), 176
Hydrogen in the Radiolysis of Methanol Vapour : Production of (Dr. G. M. Meaburn, Dr. F. W. Mellows and Dr. A. Reiffsteck), 1301
Hydrogeology (J. B. Lamarck), *review* by Prof. S. I. Tomkeleff, 961
Hydroxyapatite : Crystal Structure of (Dr. M. I. Kay *et al.*), 1050
Hydroxycinnamic Acids and Related Compounds, 928
Hydroxyindole-*O*-methyl-Transferase, Melatonin, and Serotonin in a Metastatic Parenchymatous Pinealoma : Demonstration of (Dr. R. J. Wurtman, Dr. J. Axelrod and Dr. R. Toch), 1323
Hydroxyl Radical : Infra-red Absorption of the (J. F. Ogilvie), 572
Hymenoptera : Alarm Substances and Alarm Behaviour in Social (Dr. U. W. Maschwitz), 324
Hyperglycæmia and Hypothalamic Activation : Urethane (Dr. H. Reinart), 889
Hyperpolarization of a Neurone Membrane by Barium (Dr. S. Nishi and H. Soeda), 761
Hypertension : Plasma Angiotensinase Activity in Human (Dr. P. Biron *et al.*), 1096
Hypertensive Substance in the Serum of Rats : A Non-dialysable, Heat-stabile, (Dr. Th. Kenner and Dr. W. Waldhäusl), 581
Hypothalamic Activation : Urethane Hyperglycæmia and (Dr. H. Reinert), 889
Hypothalamic Stimulation on the Erythropoietic Response in the Rhesus Monkey : Effects of (Prof. E. A. Mirand and Dr. J. T. Grace, jun., G. S. Johnston and G. P. Murphy), 1163
Hypothermia on the Radioprotective Effects of β-Mercaptoethylamine : Influence of (Dr. E. Magdon), 484

IBM Scholarships, 1141
Ice Crystals in Strong Electric Fields : Aggregation of (Dr. J. Latham and C. P. R. Saunders), 1293
Ice Nucleation : Hydrogen-bonding Patterns and (V. A. Garten and R. B. Head), 573
Ice Shelf : Radio Echo Sounding through an (M. E. R. Walford), 317
Iconographia Mycologica, VIII, IX and X (O. Verona and T. Benedek), *review* by R. W. G. Dennis, 316
Identification of a Kinetin-like Substance from Pea Seedlings, *Pisum sativum* (P. K. Biswas), 297
Identity of *Pseudomonas* Cytochrome Oxidase with Pseudomonas Nitrite Reductase (Dr. T. Yamanaka), 253
Iggo, Prof. A. : Temperature Discrimination in the Skin, 481
Ilan, J., and Johnstone, R. M. : Metabolism of Ehrlich Ascites Carcinoma Cells Grown in Mice on a Meat Diet, 1061
Illite : Far Infra-red Spectra of Montmorillonite, Kaolinite and (Prof. E. E. Angino), 569
Illumination : Formation of Isorhodopsin in the Frog's Eye during Continuous (T. Reuter), 784
Illusory Perception as a Constancy Phenomenon (Dr. L. B. Brown and Dr. L. Houssiadas), 302 ; (Prof. R. L. Gregory), 302
Image of Chile, 914
Imipramine and Structurally Related Compounds : Inhibition of Uptake of Tritiated-noradrenaline in the Intact Rat Brain by (Dr. J. Glowinski and Dr. J. Axelrod), 1318
Immune Responses *in vivo* : Effect of Actinomycin *C* on (I. N. Brown), 487
Immunity : Role of Debris of Tumour Ascitic Fluid in Transplantation (Dr. I. Hilgert *et al.*), 704
Immunized Pigs : Techniques for the Measurement *in vitro* of Tissue Sensitization in (D. Allan *et al.*), 895
Immunized Rabbits : Cell-bound and Cell-binding Antibody in the Peripheral Blood of (Dr. E. Sorkin), 794
Immunochromatographic Partition of Soluble Antigens on Columns of Insoluble Diazo-gamma-globulins (Dr. S. DeCarvalho, A. J. Lewis, Dr. H. J. Rand and J. R. Uhrick), 265
Immunogenic Complexes of the Hexacanth Tapeworm Embryo : Species Specificity of the (Dr. M. A. Gemmell), 705
Immunological Paralysis by Injection of a Specific Depolymerase : Breaking of (M. S. Brooke), 1319
Immunological Response to Implanted Adult Dwarf Tapeworms (Prof. R. M. Coleman and L. M. deSa), 397
Immunologically Identical to 19 *S* Gamma-1 (beta-2)-*M*-globulin, a New Protein of Horse Serum : 7 *S* Globulin, (Dr. G. Sandor *et al.*), 795
Immunology, Research in (WHO Technical Report Series No. 286), 830
'Immunosympathectomized' Rat : Sources of Noradrenaline in the (Dr. M. Vogt), 1315
'Impact Contamination' of the Ilokoia Carbonaceous Chondrite (Prof. G. Mueller), 567
Imperial Chemical Industries, Ltd. (Petrochemical and Polymer Laboratory), 920
Implantation Site on the Development of Grafted Limb Bud Mesoderm in Chick Embryos : Effect of the (R. Amprino and D. A. Bonetti), 298
Implanted Adult Dwarf Tapeworms : Immunological Response to (Prof. R. M. Coleman and L. M. deSa), 397
Imploding Bubbles : Jets from (R. W. Watson and F. C. Gibson), 1296
Imprinting to a Static Feature of the Home Environment (A. Taylor and K. F. Taylor), 1117
Imrie, K. S., *et al.* : Rotation Rate of Venus measured by Radar Observations, 1964, 63
Incorporation of ^{14}C-Glucose and ^{14}C-Glucose 6-phosphate into Glycogen and CO_2 by Rat Liver Slices (E. Figueroa and A. Pfeifer), 576
Increase of Muscle Permeability to Aldolase in Several Experimental Atrophies (C. Pellegrino and C. Bibbiani), 483
Indanetrione Hydrate Solutions : Stability of (Dr. S. Jacobs), 71
India : Scientific Societies in (A. Rahman *et al.*), 1250
India at Mid-passage, 22
Indian Brain Research Association, 1037
Indian Institute of Technology, Delhi, 729
Indian Journal of Cancer, I, No. 1, October, 1963, 429
Indian Ocean : Equatorial Undercurrent in the Western (Dr. J. C. Swallow), 436
Indian Science : Organization and Administration of, 528
Induction of Immunity and of Unresponsiveness to Parental Marrow Grafts in Adult F_1 Hybrid Mice (Dr. Cudkowicz and Dr. J. H. Stimpfling), 450
Industrial Archæology, 229
Industrial Research in Britain, 334
Industrial Research and Development, 1036
Industrial Safety, fourth world congress, 330
Industry : Economics and Sociology of (Prof. P. S. Florence), *review* by Prof. T. W. Hutchison, 718
Polymer Research for (W. Heap), 1030
Inert Gas Narcosis : Solubility Relations of Fluorine Compounds and (R. A. Dawe *et al.*), 789
Infants : Trigeminus Reflex in Young (H. C. Hopf *et al.*), 1312
Inferior Vena Cava in the Rat : Drinking caused by Constriction of the (Dr. J. T. Fitzsimons), 479
Influence of Motivation, Perception and Attention on Age-related Changes in Short-term Memory (J. Inglis), 103
Influenza Virus : Action of Phospholiphase *C* on (Dr. Hiromichi Mizutani and Hiroko Mizutani), 781
Influenza Virus Ribonucleic Acid to the Action of Actinomycin *D* : Resistance of Synthesis of (Dr. A. G. Bukrinskaya), 205
Information : Machine Learning from Noisy (N. V. Findler), 103
Infra-nuclear Distribution of Transaminases (Dr. K. M. Wang and Prof. T-Y. Wang), 880
Infra-red Absorption of the Hydroxyl Radical (J. F. Ogilvie), 572
Infra-red Spectra of Montmorillonite, Kaolinite and Illite : Far (Prof. E. E. Angino), 569
Infra-red Spectra of some Carbon-14-labelled Acids, an Ester and Sodium Salt : Isotope Effects in the (B. H. Baxter and A. F. C. Horsler), 675
Inglis, J. Influence of Motivation, Perception and Attention on Age-related Changes in Short-term Memory, 103
Ingram, Dr. D. L. : Heat and Life, *review*, 615
Ingram, Dr. M., *et al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
Ingram, Dr. T. T. S. : Cerebral Function in Infancy and Childhood, third revised German edition, *review*, 413
Inheritance by Handedness and Cerebral Dominance : Model of the (Mrs. M. Annett), 59
Inhibition of Interferon Biosynthesis by Actinomycin *D* (Prof. R. R. Wagner), 49
Inhibition of Protein Synthesis by Acridine Orange (Dr. A. V. Zelenin and Mrs. E. A. Liapunova), 45
Inhibition of Uptake of Tritiated-noradrenaline in the Intact Rat Brain by Imipramine and Structurally Related Compounds (Dr. J. Glowinski and Dr. J. Axelrod), 1318
Ink Blue as a ph Indicator for Certain Biological Systems (M. Baxter and J. R. R. Cooper), 1105
Inman, Dr. D. R., and Cooper, Dr. E. H. : Ultrastructure of Human Leucocytes Synthesizing DNA, 894
Innes, The John. Institute (Dr. E. C. Humphries), 232
Innes, John. Institute : Fifty-fourth Annual Report, 1963, 232
Inorganic Ultramicroanalysis (I. P. Alimarin and M. N. Petrikova), *review* by Dr. D. T. Lewis, 514
Inouye, T., *et al.* : Enzymatic Oxidation of Galactose-6-phosphate, 1304
Insect : A Large Amount of Trehalose in a Frost-resistant (E. Asahina and K. Tanno), 1222
Insect Inorganic Pyrophosphatase : Electrophoresis of an (Dr. E. N. Lambremont and R. M. Schrader), 883
Insecticide Synergists on Duration of Sleep induced in Mice by Barbiturates : Effect of (Dr. B. C. Fine and J. O. Molloy), 789
Insects : Generalized Hovering-Flight for (Prof. G. Houghton), 666
High-intensity Flash Discharge as a Source of Radiant Energy for Sterilizing (D. F. Riordan), 1332
The Life of (Prof. V. B. Wigglesworth), *review* by Prof. G. C. Varley, 955
Insects as Vectors of Red Ring Disease : Role of (E. A. C. Hagley), 905
Insects and Birds : Fluttering Flight Mechanisms in (Prof. G. Houghton), 447
In situ Detection of an Ionospheric Electric Current (Dr. K. Burrows and Dr. S. H. Hall), 721
Isolation of a Highly Purified Encephalitogenic Protein from Bovine Cord (Dr. R. F. Kibler, R. H. Fox and Prof. R. Shapira), 1273
Instability of Temperate ice-sheets owing to a Feed-back Mechanism (M. L. Liboutry), (203, 627) ; *corrigendum*, 231
Institute of Mathematics and its Applications, the first inaugural presidential adress, 231
Institute of Physics and the Physical Society : Conference on "Optics in Process Control", 732
Second Annual Conference on "Solid-State Physics", 732
Institute of Statisticians : Election of Officers, 333
Institution of Civil Engineers : Mr. R. M. Wynne-Edwards, presidential address, 730
Institution of Mining and Metallurgy, president for 1965-66, elected, 431
Institution of the Rubber Industry : Twentieth Foundation Lecture, 830
Insulin : Uncouplers of Oxidative Phosphorylation and Teratogenic Activity of (Prof. W. Landauer and E. M. Clark), 285
Interaction between Lower and Upper Tropical Tropospheres (C. R. V. Raman and Y. Ramanathan), 31
Interaction of Cytochrome *c* with Yeast D(-) Lactic Oxidase (Dr. C. Gregolin, Dr. P. Scalella and Dr. A. D'Alberton), 1302
Interaction of Phosphorus-32 and Carbon-14-labelled Tritolyphosphate with Glass Surfaces (Dr. M. E. Schrader and I. Lerner), 759
Interactions of Peroxidases and Catalases between *Phaseolus vulgaris* and *Pseudomonas phaseolicola* (Halo Blight of Bean), (Prof. K. Rudolph and Prof. M. A. Stahmann), 474
Interdiffusion in Zirconium-Aluminium and Zircaloy-Aluminium System (G. P. Tiwari and B. D. Sharma), 178
Interferon : A Rich Source of Mouse (N. B. Finter), 1114
Interferon Appearance in Mice injected with Bacteria or Bacterial Endotoxin : Patterns of (Prof. W. R. Stinebring and Prof. J. S. Youngner), 712
Interferon Biosynthesis by Actinomycin *D* : Inhibition of (Prof. R. R. Wagner), 49
Interferon Information Exchange Group, 627
Intergalactic Gas as a Possible Absorber of Extra-galactic Radio Noise (Dr. D. W. Sciama), 767
Interhemispheric Transfer of Avoidance Conditioning : Lateralization and One-trial (Dr. R. B. Ross and Dr. I. S. Russell), 909
Intermediary Reactions in the Water-splitting Part of Photosynthesis (V. Bültemann, H. Rüppel and Prof. H. T. Witt), 646
Intermetallic Compound Formation : Poisoning of the Surface of Platinum Metals by (W. R. Buck, III and H. Leidheiser, jun.), 177
Intermolecular Potential Energy Functions for Simple Molecules (J. H. Dymond, M. Rigby and Dr. E. B. Smith), 678
International Commission on Zoological Nomenclature, 331, 429
International Encyclopedia of Physical Chemistry and Chemical Physics : Topic II : Vol. I, (edited by M. Blackman), *review* by Dr. G. L. Squires 5
International Geological Congress, twenty-second session, 431
International Union for Conservation of Nature : *Liquid Assets*, 628
International Years of the Quiet Sun, 1964-65 (Prof. W. J. G. Beynon), 621
Interphase : Sedimentation Rate of Cells in Metaphase as compared with Cells in (Dr. D. A. Arvan *et al.*), 1225
Interpolation of Franck-Condon Factors (Prof. R. W. Nicholls), 373
Interpretation of Mass Spectra of Organic Compounds (Dr. H. Budzikiewicz, Prof. C. Djerassi and Dr. D. H. Williams), *review* by Dr. F. G. Mann, 965
Interstellar Flux of Gamma-rays : Detection of an (Dr. A. E. Metzger *et al.*), 766
Interstellar OH Lines : Spectrum and Relative Intensities of (A. H. Barrett and A. E. E. Rogers), 62

Intestinal Absorption : Mechanism of : The Concept of a Spectrum of Intracellular Plasma (Dr. J. A. Nissim), 148
Intestinal Crypt Lesions in Neonatally Thymectomized Hamsters (Dr. R. C. Hard, Prof. C. Martinez and Prof. R. A. Good), 455
Intestinal Sugar Transport, First Receptor in : the Effect of Phloridzin and of Cetrimide on the Intestinal Absorption of α-D-Glucosamine, L-Glucose and D-Xylose (S. L. Hart and Dr. J. A. Nissim), 51
Intracellular Sodium and Potassium Concentrations in Plant and Animal Cells : Effect of Calcium on (Prof. G. A. Morrill et *al.*), 641
Intravital Fluorescence Microscopy in the Qualitative Evaluation of the Interaction of Acridine Orange with Nucleic Acid in Intact Living Human Organs (Dr. M. Sherif), 390
Introduction to Infra-red and Raman Spectroscopy (N. B. Colthup, L. H. Daly and S. E. Wiberley), *review* by Dr. L. J. Bellamy, 962
Introduction to Satellite Geodesy (Prof. Lal. Mueller), *review* by D. G. King-Hele, 514
Introduction to the Theory of the Formation of Frozen Rocks (I. A. Tyutyunov), *review* by Dr. E. I. Hamilton, 816
Invention and Discovery, 1017
Inverse Compton Effect as a Possible Cause of the X-Ray Radiation of Solar Flares (Dr. L. W. Acton), 64
In vitro Culture of Seedlings of *Striga senegalensis* Benth (S. N. C. Okonkwo), 1108
In vitro Cytotoxic Effect of Lymphoid Cells from Mice Immunized with Allogeneic Tissue (Dr. T. Vainio, Dr. O. Koskimies, Dr. P. Perlmann, Mrs. H. Perlmann and Prof. G. Klein), 453
In vitro Production of Embryos from Anthers of *Datura* (S. Guha and S. C. Maheshwari), 497
In vivo Maturation of Immature Reticulocytes transfused into a Normal Rabbit (R. L. Millette and E. R. Glowacki), 1207
Iodine as a Scavenger for Hydrogen Atoms in Irradiated Ethanol (N. T. Barker and Prof. J. H. Green), 872
Iodine-131 Injections on the Survival of Dystrophic Mice : Influence of Diet and (R. F. Borgman), 389
Iodine-131 Sources : Low-background Beta Counters for (Dr. C. F. Barnaby), 68
Ion Gyrofrequency Phenomenon observed in Satellites (R. L. Smith et *al.*), 274
Ion Molecule Reaction : Production of $C_2O_4^+$ in an (Dr. J. F. Paulson et *al.*), 377
Ionic Polymers and Leukæmogenic Viruses Relative to Nucleic Acids in *Drosophila melanogaster* : Mutagenicity of (Dr. O. G. Fahmy and Dr. M. J. Fahmy), 46
Ionization Chamber and a Determination of Boag's Constant for Air : Saturation Characteristics of a Spherical (Dr. T. E. Burlin and S. R. Husain), 670
Ionization of Mercury by Alkali Positive Ions (Prof. R. M. Chaudhri, H. A. Khan, K. A. Shoaib and M. M. Chaudhri), 987
Ionizing Radiation given by Alcohols to *Salmonella typhimurium LT2* : Relationship between Chemical Structure and the Extent of Protection against (A. B. Sidle), 597
Ionosphere at Middle Latitudes : Some Irregularities observed simultaneously in the Upper and Lower (F. Du Castel and J. M. Faynot), 984
Ionospheric Electric Current : The *in situ* Detection of an (Dr. K. Burrows and Dr. S. H. Hall), 721
Iontophoretically Applied Drugs : Discharge Patterns of Elements in Cat Cerebellar Cortex, and their Responses to (I. McCance and Dr. J. W. Phillis), 844
Iralu, Dr. V. : Production of *Trypanosoma cruzi* Cysts *in vitro*, 486
Ireland, W. : Signal Strength Variations of Satellite Signals, 368
Irish Meteorological Service : Director appointed, 333
Irish Tubificidae, 732
Iron, Cast : Austenite/Carbon Reaction in (R. A. Cresswell), 465
Iron-chlorotic Barley (*Hordeum vulgaris*) Seedlings : Catalase Activity of a Crude Enzyme Preparation from (S. Kotaka et *al.*), 1198
Iron-deficient Low-temperature Pyrrhotite (F. J. Sawkins, Prof. A. C. Dunham and Dr. D. M. Hirst), 175
Iron-deficient Rats : Achromotricia in (R. P. Cusack and Dr. W. D. Brown), 582
Iron and Steel Industry, 828
Iron and Steel Institute, Medal of the, awarded to the Cleveland Institution of Engineers, 231
Irradiated Cercariæ : *Schistosoma mansoni* : Humoral Transfer of Protective Factors produced by (Dr. A. Perlowagora-Szumlewicz), 1009
Irradiated Vacuum Cavity Chamber : Measurement of the Emission of Low-energy Electrons in an (Dr. T. E. Burlin and S. R. Husain), 1078
Irradiated Vacuum Cavity Chambers : Electron Transfer in (Dr. T. E. Burlin and S. R. Husain), 563
Irradiation : Protection with 2-β-Aminoethylisothiourea, Glutathione and Serotonin of Mice against Wholebody (Dr. J. R. Maisin), 196
Irradiation Processes with Microbiological Objectives : Tentative Classification of Food (Dr. H. E. Goresline et *al.*), 237
Irving, B. A. : Effect of Grain Boundaries on the Diffusional Growth of Oxides on Metals, 1082
Irwin, S., et *al.* : Inhibition of Phenylquinone-induced Writhing by Narcotic Antagonists, 189
Isentropic Stagnation Temperature of a Fluid : A General Expression for the (A. A. R. El Agib), 989
Isidore of Seville, 331
Iso-immune Cytolysis using Radiolabelled Target Cells : Applications of (Dr. A. R. Sanderson), 250
Isolation of Methylcobalamin from Natural Source Material (Dr. K. Lindstrand), 188
Isolation of a Mucopeptide from the Surface of Ehrlich Ascites Tumour Cells (O. K. Langley and Dr. E. J. Ambrose), 53
Isolation of a Serologically Active, Fucose-containing, Trisaccharide from Human Blood-group Lea Substance (V. P. Rege, T. J. Painter, W. M. Watkins and Prof. W. T. J. Morgan), 740
Isolation and Identification of the Initial Peak of the Early Receptor Potential (Dr. W. L. Pak and Dr. R. A. Cone), 836
Isolation and Significance of *Streptococcus faecalis sensu strictu* (G. C. Mead), 1224
Isorhodopsin in the Frog's Eye during Continuous Illumination : Formation of (T. Reuter), 784
Isotope Effects in the Infra-red Spectra of some Carbon-14-labelled Acids, an Ester and Sodium Salt (B. H. Baxter and A. F. C. Horsler), 675
Isotope Position Experiments : Elucidation of the Biosynthetic Pathway of Thyroidal 3 : 5 : 3'Triiodothyronine by Means of (Dr. L. G. Plaskett and Dr. C. F. Barnaby), 1271
Isotopic Ages of Assynt Dykes (Dr. C. R. Evans and Dr. J. Tarney), 638
Isotopic Investigations of Nitrogen Fixation in Non-legume Root Nodules (Dr. G. Bond), 600
Isozymes : Effect of Amitosis on the Distribution of Human Lactic Acid Dehydrogenase (Dr. E. D. Wachsmuth), 681
Isozymes of Salivary Amylase (Prof. J. Muus and J. M. Vnenchak), 283
Isozymes and Ageing of Erythrocytes : Lactic Dehydrogenase (J. Rosa and F. Schapira), 883
Isselbacher, Prof. K. J., and Hyams, Dr. D. E. : Prevention of Fatty Liver by Administration of Adenosine Triphosphate, 1196
Ito, S., and Joslyn, Prof. M. A. : Presence of Several Phenolic Components in Fruit Proanthocyanidins, 475
Ivanov, A. V. : Pogonophora, *review* by Dr. S. M. Manton, 1020
Ives, The Frederic, Medal for 1964 awarded, 526

JACKSON, Dr. A. L., et *al.* : Antibody Production by Leucocytes in Peripheral Blood, 1320
Jackson, C. P., and Ramamurti, Prof. K. : Pigment Formation by *Acetobacter acetigenum* in a Lactate-buffered Glycerol Medium, 402
Jacob, Dr. J., and Sirlin, Dr. J. L. : Sequential and Reversible Inhibition of Synthesis of Ribonucleic Acid in the Nucleolus and Chromosomes : Effect of Benzamide and Substituted Benzimidazoles on Dipteran Salivary Glands, 545
Jacobs, A. S., and Ranney, Dr. H. M. : Simultaneous Occurrence of Hæmoglobins C and Lepore in an Afro-American, 163
Jacobs, P., et *al.* : Procedure for the Standardization of Tissue Culture Media, 146
Jacobs, Dr. S. : Stability of Indanetrione Hydrate Solutions, 71
Jacobson, A., et *al.* : Dream Deprivation : an Experimental Reappraisal, 1337
Janíček, G., and Hrdlička, Dr. J. : Volatile Amines as Components of Toasted Oat Flakes, 1201
Janisch, Dr. R. : Sub-microscopic Structure of Injured Surface of *Paramecium caudatum*, 200
Janković, Prof. B. D., et *al.* : Suppression of Experimental Allergic Encephalomyelitis in Rats and Chickens treated with Reserpine, 1101
Janota-Bassalik, L., and Wright, Prof. L. D. : Pimelic Acid as a By-product of Azelaic Acid Degradation by *Pseudomonas* sp., 501
Janowski, Z., and Speakman, Prof. J. B. : Heat-yellowing of Wool and Silk, 779
Janz, Prof. G. J., et *al.* : Transport Processes in Low-melting Fused Salts, 1188
Jarai, Dr. M., et *al.* : Biochemical Chlorination of *Streptomyces aureofaciens*, 1307
Jarrige, P., et *al.* : Beta-galactosidase of *Helix pomatia*, 686
Jaundiced Homozygous Gunn Rat : Serum Enzymes in the (Dr. T. Hargreaves and B. Thom), 1323
Jaward, M. J., et *al.* : Succinate Metabolism in *Salmonella typhimurium*, 1285
Jayakar, S. D., and Spurway, Dr. H. : Biomodality of Laying-Hatching Times in *Testudo elegans* Schoepff (Chelonia), 603
Jayle, Max F., and Pasqualini, Jorge R. (edited by) : Structure and Metabolism of Corticosteroids, *review* by Prof. J. Patterson, 411

Mays, C. M., *et al.* : Trophic Level Effect on the Accumulation of Cæsium-137 in Cougars feeding on Mule Deer, 708
Mazes, 'Unrewarded' Exploration and Learning of Complex, by Wild and Domestic Mice (Prof. D. H. Brant and Prof. J. L. Kavanau), 267
Meaburn, Dr. G. M., *et al.* : Production of Hydrogen in the Radiolysis of Methanol Vapour, 1301
Mead, G. C. : Isolation and Significance of *Streptococcus faecalis sensu strictu*, 1224
Means, Dr. W. D., and Rogers, Dr. J. : Orientation of Pyrophyllite Synthesized in Slowly Strained Materials, 244
Measurement of the Emission of Low-energy Electrons in an Irradiated Vacuum Cavity Chamber (Dr. T. E. Burlin and S. R. Husain), 1078
Meat Diet : Metabolism of Ehrlich Ascites Carcinoma Cells Grown in Mice on a (J. Ilan and R. M. Johnstone), 1061
Mechanical Twinning of Crystals (M. V. Klassen-Neklyudova), *review* by Dr. J. H. Brunton, 613
Mechanics of Aerosols, The (N. A. Fuchs), *review* by J. F. Croft, 1236
Mechanism for Nitrogen-increased Shoot/Root Ratios (Dr. S. R. Wilkinson and Prof. A. J. Ohlrogge), 902
Mechanism of Enzyme Catalysis (Prof. G. G. Hammes), 342
Mechanism of Erection and Ejaculation in the Bull and Ram (J. W. Watson), 95
Mechanism of Intestinal Absorption : The Concept of a Spectrum of Intracellular Plasma (Dr. J. A. Nissim), 148
Mechanism of β-Ketoadipate Formation by Bacteria (L. N. Ornston and Prof. R. Y. Stanier), 1279
Mechanisms of Regulation of Hepatic Glycogen Synthesis (Prof. D. F. Steiner), 1171
Medawar, Dr. P. B., and Brent, Dr. L. : Nature of the Normal Lymphocyte Transfer Reaction, 90
Median Eminence Extracts : Luteinizing Hormone-like Activity in Human (H. Croxatto *et al.*), 584
Medicago : The Annual Species of (C. C. Heyn), *review* by R. D. Meikle, 316
Medical Research Council : *Current Medical Research*, 1256
Fellowships in Medicine, 230
New Research Units and Groups, 128
Medical Research and the World Health Organization (Dr. G. Lapage), 232
Medicine : Radioactive Metal Mobilization in (Prof. A. Catsh), *review* by Dr. H. Spencer, 112
Medicines, New, 732
Mediterranean and Red Sea : Magnetic, Gravity and Depth Surveys in the (T. D. Allan *et al.*), 1245
Mee, Dr. L. K., *et al.* : Inactivation of Chymotrypsin in Aqueous Solution by Atomic Hydrogen, 1056
Meester, J. : A Systematic Revision of the Shrew Genus *Crocidura* in Southern Africa, *review* by Dr. G. B. Corbet, 1022
Meheriuk, M., and Spencer, Prof. M. : Effects of Nitrogen, and of Respiratory Inhibitors, on Ethylene Production by a Sub-cellular Fraction from Tomatoes, 43
Meigh, Dr. D. F., *et al.* : Effect of Damage and Fungal Infection on the Production of Ethylene by Carnations, 92
Meikle, R. D. : Annual Species of *Medicago*, *review*, 316
Sertum Anglicum, 1788, *review*, 311
Meiosis in *Ascobolus immersus* : 'Selfers' and High Mutation Rate during (A. Paszewski and S. Surzycki), 809
Melatonin, and Serotonin in a Metastatic Parenchymatous Pinealoma : Demonstration of Hydroxyindole-*o*-methyl Transferase, (Dr. R. J. Wurtman *et al.*), 1323
Melatonin by the Epiphysis of *Xenopus laevis* : Uptake of Labelled Precursors of (H. M. Charlton), 1093
Mellitic Acid : Metabolism of Coumarin by a Micro-Organism : *O*-Coumaric Acid as an Intermediate between Coumarin and (Dr. C. C. Levy), 1059
Mellor's Comprehensive Treatise on Inorganic and Theoretical Chemistry, Vol. 8, Supplement 1, *review* by Prof. J. R. Partington, 511
Mellows, Dr. F. W., *et al.* : Production of Hydrogen in the Radiolysis of Methanol Vapour, 1301
Melting and Freezing (Prof. A. R. Ubbelohde), 1046
Melville, Sir Harry, and Gowenlock, B. G. : Experimental Methods in Gas Reactions, second edition, *review* by D. H. Desty, 965
Membrane Potential of Electrolyte-depleted Muscle Fibres (Dr. R. P. Kernan), 83
"Membrane Problems", symposium, 526
Membranes : Fat-soluble Vitamins and Biological (Dr. J. A. Lucy and J. T. Dingle), 156
Memory : Influence of Motivation, Perception and Attention on Age-related Changes in Short-term (J. Inglis), 103
Semantic and Acoustic Similarity in Short-term (A. D. Baddeley), 1116
Mendelsohn, E. : Heat and Life, *review* by Dr. D. L. Ingram, 615
Mendenhall, jun., A. L., and Mendenhall, Dr. R. M. : Lung Alveolar Surfactant, Lung Elasticity, and Lung Stability, 747
Mendenhall, Dr. R. M., and Mendenhall, jun., A. L. : Lung Alveolar Surfactant, Lung Elasticity, and Lung Stability, 747
Meningopneumonitis Viral Antigenic Preparations : Comparative Immunological, Biological and Biophysical Behaviour of (G. C. Parikh and Prof. I. L. Shechmeister), 1013
Mentall, J. E., *et al.* : Laser Excitation of Powdered Solids, 1295
Menzel, Prof. D. H., *et al.* : Stellar Interiors, *review* by Dr. R. J. Tayler, 972
Menzel, Prof. R. W., and Perkins, F. O. : Maintenance of Oyster Cells *in vitro*, 1106
Meprobamate injected into the Gravid Rat : Postnatal Behavioural Effects of (Dr. M. Kletzkin *et al.*), 1206
Mercaptans and Thioethers : Significance of the Solubility of Hydrogen Halides in (M. J. Frazer and Dr. W. Gerrard), 1299
β-Mercaptoethylamine : Influence of Hypothermia on the Radioprotective Effects of (Dr. E. Magdon), 484
Mercury by Alkali Positive Ions : Ionization of (Prof. R. M. Chaudhri *et al.*), 987
Mercury *tert*-Butyl Mercury Mercaptide : Polymeric Structure of (Prof. N. R. Kunchur), 468
Mercury in Mouse Brain after Inhalation of Mercury Vapour and after Intravenous Injection of Mercury Salt, (Dr. M. Berlin and L. G. Johansson), 85
Merrill, Dr. P. W. : Space Chemistry, *review* by J. A. Dawe, 971
Mesocricetus auratus Waterhouse : Cyclical Behavioural Activity in Pregnant Golden Hamster (M. P. M. Richards), 1327
Mesoderm in Chick Embryos : Effect of the Implantation Site on the Development of Grafted Limb Bud (R. Amprino and D. A. Bonetti), 298
Messel, Prof. H., and Gold, Prof. T. : A New Joint American-Australian Astronomy Center, 18
Mester, Dr. L., and Stoward, Dr. P. J. : Formazan Reaction as a Confirmatory Test for Aldehyde Groups in Histochemistry, 488
Metabolic Effects of Oxytocin in the Chicken (Dr. Y. Kook, K. B. Cho and K. O. Yun), 385
Metabolic Fate of some Chlorinated Phenoxyacetic Acids in the Stem Tissue of *Avena sativa* (E. W. Thomas, Dr. B. C. Loughman and R. G. Powell), 286
Metabolic Fate of 2,4-Dichlorophenoxyacetic Acid in the Stem Tissue of *Phaseolus vulgaris* (Dr. E. W. Thomas, Dr. B. C. Loughman and Dr. R. G. Powell), 884
Metabolic Reactions Research Unit, 128
Metabolism : Ethylene Oxide an Antagonist of Ethylene in (M. Lieberman *et al.*), 756
Metabolism of Coumarin by a Micro-Organism : *O*-Coumaric Acid as an Intermediate between Coumarin and Melilotic Acid (Dr. C. C. Levy), 1059
Metabolism of Ehrlich Ascites Carcinoma Cells Grown in Mice on a Meat Diet (J. Ilan and R. M. Johnstone), 1061
Metabolism of Nicotine by Tobacco-feeding Insects (Dr. L. S. Self, Dr. F. E. Guthrie and Dr. E. Hodgson), 300
Metal Films : Adsorption of Krypton and Xenon on Evaporated (Z. Knor and V. Ponec), 466
Electrical Conduction in Thin Aggregated (Dr. R. M. Hill), 35
Metal Ion Catalysis in the Hydrolysis of Potassium Ethyl Oxalate (Dr. R. W. Hay and N. J. Walker), 1189
Metal Oxides : Scavenging of 'Dissolved' Organic Matter from Sea-water with Hydrated (Dr. P. M. Williams and A. Zirino), 462
Metallic Phases in some Stone and Stony-Iron Meteorites : Composition of the (S. J. B. Reed), 374
Metallic Sheen in *Pseudomonas aeruginosa* (Dr. A. H. Wahba), 502
Metals : Effect of Grain Boundaries on the Diffusional Growth of Oxides on (B. A. Irving), 1082
Metamorphism in Britain : Age of Caledonian Orogeny and (Dr. T. G. Miller), 358 ; (F. J. Fitch *et al.*), 358
Metamorphosis : Thalidomide and Induced Amphibian (Dr. J. R. Tata), 939
Metaphase as compared with Cells in Interphase : Sedimentation Rate of Cells in (Dr. D. A. Arvan *et al.*), 1225
'Metarchon' : A New Term for a Class of Non-toxic Pest Control Agents (R. H. Wright), 603
Meta-stable Ions in Double-focusing Mass Spectrometers (Dr. J. H. Beynon, R. A. Saunders and A. E. Williams), 67
Metcalfe, Dr. C. R.: Annual Rings in Big Sagebrush, *Artemisia tridentata*, *review*, 514
Meteorite : Cosmic-ray-induced Particle Tracks in a (M. Maurette *et al.*), 821
Organized Element Distribution in Relation to Size in the Orgueil (Dr. G. Claus and Dr. E. A. Suba-C.), 118
Meteorite : Woolgorong Stony, 925
Meteorites : Composition of the Metallic Phases in some Stone and Stony-Iron (S. J. B. Reed), 374
Origin of (B. J. Levin), 946
Origin of the Canyon Diablo No. 2 and No. 3 (Dr. D. Heymann), 819

Meteoritic Data : Estimation of Half-lives from (Dr. M. E. Lipschutz), 1289
Meteoroid : Mass of the Canyon Diablo (Prof. C. Sharp Cook), 867
Meteorological Factors in Radiocommunications at very Short Wave-lengths (Dr. R. L. Smith-Rose), 518
Methanol Vapour : Production of Hydrogen in the Radiolysis of (Dr. G. M. Meaburn *et al.*), 1301
Methoden der Organischen Chemie, Band XII/1, VI/2, and XIV/2 (von Houben-Weyl, Herausgegeben von Eugen Müller), *review* by Dr. F. G. Mann, 1122
Methylamphetamine on the Psychomotor Depression produced by Adrenaline in Mice : Effect of (Prof. E. Fischer, R. L. Ludmer and S. R. Kruglikoff), 695
20-Methylcholanthrene : Existence in the Thymus of a Factor protecting the Skin of the Mouse against the Induction of Skin Cancers induced by (Prof. J. Maisin), 1211
Methylcholanthrene-induced Mouse Sarcomas : Effect on Tumour Growth in Syngeneic Recipients of Antibodies against Tumour-specific Antigens in (G. Möller), 846
Methylcobalamin from Natural Source Material: Isolation of (Dr. K. Lindstrand), 188
Methylhistamine and Histamine in the Urine of Women during the Elaboration of Œstrogen (Prof. J. P. Green, Dr. D. H. Fram and Prof. N. Kase), 1165
Methyl Linolenate as an Essential Nutrient for the Cabbage Looper, *Trichoplusia ni* (Hübner) (G. M. Chippendale, S. D. Beck and Prof. F. M. Strong), 710
3-Methylxanthosine (Dr. M. Adler and Prof. A. B. Gutman), 681
Metzger, Dr. A. E., *et al.* : Detection of an Interstellar Flux of Gamma-rays, 766
Meyerott, A. J., *et al.* : Upper Limit to Jupiter's X-ray Flux on September 30, 1962, 982
Michael, B. D., *et al.* : Pulsed Radiolysis of *Cyclo*hexane Solutions : Evidence for Reactions of Electrons, 1187
Microbial Classification, 425
Microbiological Objectives : Tentative Classification of Food Irradiation Processes with (Dr. H. E. Goresline *et al.*), 237
Microdroplet Assay of Human Serum Cytotoxins (Dr. P. I. Terasaki and J. D. McClelland), 998
Microfibrils : Fine Structure of Native Cellulose (Dr. R. St. John Manley), 1155
Microfilm Readers in Petrography : Applications of (H. B. Milner), 1262
Micro-organism : Metabolism of Coumarin by a : *O*-Coumaric Acid as an Intermediate between Coumarin and Melilotic Acid (Dr. C. C. Levy), 1059
Polysaccharide resembling Alginic Acid from a *Pseudomonas* (Dr. A. Linker and Dr. R. S. Jones), 187
Micro-organisms : Preservation of the Heterozygous Diploid Condition in Industrial (Dr. K. D. Macdonald), 404
Micropalæontology in Two Late Cænozoic Cores from the Pacific Ocean : Relationship of Palæomagnetic Reversals and (Dr. C. G. A. Harrison and Dr. B. M. Funnell), 566
Micropinocytosis in Trophocyte of *Bombus* : Occurrence of Microvilli and (C. R. Hopkins and Dr. P. E. King), 298
Micropulsation Activity : Simultaneous Measurements and Spectral Analysis of (R. L. Komack *et al.*), 534
Microscopy : Relationship between Radiation Dose and Giant Cells in the Surviving Cell Population of Mouse Marrow as Determined by Interference (H. Lee and Prof. V. Richards), 656
Microscopy, Intravital Fluorescence, in the Qualitative Evaluation of the Interaction of Acridine Orange with Nucleic Acid in Intact Living Human Organs (Dr. M. Sherif), 390
Micro-slide Method permitting Autoradiography of Hæmolysin-producing Cells (Dr. K. Berglund), 89
Microvilli and Micropinocytosis in Trophocyte of *Bombus* : Occurrence of (C. R. Hopkins and Dr. P. E. King), 298
Microwave Faraday Rotation in Ferrite Powders (Dr. P. Swarup and N. Kumar), 947
Microwave Observations of the Galactic Centre Region (Dr. A. Maxwell and Dr. D. Downes), 865
Mid-Devonian Correlations : European (P. Copper), 363, *corrigendum*, 1038
Mildew : Toxicity of Captan Analogues to Oat Powdery (D. V. Richmond *et al.*), 1329
Miledi, Dr. R. : Electron-microscopical Localization of Products from Histochemical Reactions used to detect Cholinesterase in Muscle, 293
Miles, Dr. R. S. : A Reinterpretation of the Visceral Skeleton of *Acanthodes*, 457
Milk : An Inhibitory Substance present in (Dr. G. C. Cheeseman and D. J. Jayne-Williams), 688
Lysozyme Content of Human (R. C. Chandan *et al.*), 76
Milk and its Genetic Basis : Ratio of Potassium to Lactose in Cows' (J. P. Walsh and Dr. J. A. F. Rook), 353
Millar, Dr. I. T., *et al.* : Tetracyanoethylene Complexes as Indicators of the Carbonyl Inductive (—I) Effect in Sterically Hindered Aromatic Ketones, 282
Miller, D. S., and Payne, P. R. : Nitrogen Balance Experiments : Some Theoretical Considerations, 480
Miller, F. A., *et al.* : Antiviral Activity of Gliotoxin and Gliotoxin Acetate, 1333
Miller, Dr. J. A., *et al.* : Age of Caledonian Orogeny and Metamorphism in Britain, 358
Miller, Dr. J. F. A. P., *et al.* : Pathogenesis of the Post-Neonatal Thymectomy Wasting Syndrome, 151
Miller, K. W., *et al.* : Solubility Relations of Fluorine Compounds and Inert Gas Narcosis, 789
Miller, M. W., and Sparrow, Dr. A. H. : Relationship between Nuclear Volume and Radiosensitivity of Different Cell Types in Gemmæ of *Marchantia polymorpha* L., 596
Miller, Prof. S. L., and Parris, M. : Synthesis of Pyrophosphate under Primitive Earth Conditions, 1248
Miller, Dr. T. G. : Age of Caledonian Orogeny and Metamorphism in Britain, 358
Miller, Dr. W. J., and Fontijn, Dr. A. : Negative Ion Formation in the Atomic Oxygen-Acetylene Reaction, 679
Millette, R. L., and Glowacki, E. R. : *In vivo* Maturation of Immature Reticulocytes transfused into a Normal Rabbit, 1207
Millin, Dr. D. J., *et al.* : Detection of 'Activated' Compounds on Paper, 286
Millott, Prof. N., and Vevers, Dr. H. G. : Axial Organ and Fluid Circulation in Echinoids, 1216
Mills, C. F., and Passmore, R. (general editors) : Proceedings of the Sixth International Congress of Nutrition, *review* by Dr. W. R. Aykroyd, 961
Milner, H. B. : Applications of Microfilm Readers in Petrography, 1262
Problems of Noise, 338
Production and Uses of Natural Graphite, *review*, 218
Progress in Concrete Research, 233
Milward, G. E., and Wroe, P. H. S. : Office Economy by O and M, *review* by T. H. Hawkins, 977
Minerals : Effect of Release of Compression on Magnetization of Rocks and Assemblies of Magnetic (Dr. T. Nagata and H. Kinoshita), 1183 ; (Dr. F. D. Stacey), 1183
Minerals and Rocks (Prof. J. F. Kirkaldy), *review* by Dr. V. A. Eyles, 719
Mingulay : The Glasgow University Exploration Society Expedition to (J. F. Robertson *et al.*), 25
Minimal Salt Load required to induce Secretion from the Nasal Salt Glands of Sea Gulls (Prof. L. Z. McFarland), 1202
Ministry of Agriculture : Agricultural Bacteriology Division, 923
Ministry of Aviation : Chief Scientist Appointed, 923
Director of Engine Research and Development, 228
Ministry of Labour, Manpower Studies No. 1 : *The Pattern of the Future*, 609
Minuria integerrima (DC) Benth : Somatic Apospory and Polyembryony in (Prof. G. L. Davis), 94
Minz, Dr. B., and Noel, Dr. P. : Effect of Rhinencephalic Lesions on Cardiovascular Reactions to Noradrenaline, 82
Mirand, Prof. E. A., *et al.* : Ability of Tamarins to Produce and Respond to Erythropoietin, 1064
Effects of Hypothalamic Stimulation on the Eryhtropoietic Response in the Rhesus Monkey, 1163
Mironov, B. F., *et al.* : Synthesis of Organosilicon Monomers, *review* by Dr. W. Gerrard, 512, 830
Mirsky, Alfred E., and Brachet, Jean (edited by) : The Cell : Biochemistry, Physiology, Morphology, Vol. 6, *review* by Prof. J. M. Mitchison, 956
Mishchenko, E. F., *et al.* : The Mathematical Theory of Optimal Processes, *review* by Dr. A. T. Fuller, 1124
Misrahy, Prof. G. A. (the late), *et al.* : Electroencephalograph during 'Feigned' Sleep in the Opossum, 162
Mitchell, H. H. : Comparative Nutrition of Man and Domestic Animals, Vols. 1 and 2, *review* by Dr. D. P. Cuthbertson, 113
Mitchison, Prof. J. M. : The Cell : Biochemistry, Physiology, Morphology, Vol. 6, *review*, 956
Mitochondrial Phosphohistidine by Radioactive Inorganic Phosphate : Rate of (Prof. E. C. Slater and A. Kemp, jun.), 1268
Mitochondrial and Cytoplasmic Enzymes for the Reduction of Fumarate to Succinate in Yeast (Dr. C. Rossi, J. Hauber and Dr. T. P. Singer), 167
Mitochondrion (A. L. Lehninger), *review* by Sir Hans Krebs, 303
Mittwoch, Dr. U. : Sex Chromosomes and Sex Chromatin, 1032
Mizutani, Hiroko, and Mizutani, Hiromichi : Action of Phospholipase *C* on Influenza Virus, 781
Mizutani, Hiromichi, and Mizutani, Hiroko : Action of Phospholipase *C* on Influenza Virus, 781
Mocquot, Dr. G., *et al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
Model of the Inheritance by Handedness and Cerebral Dominance (Mrs. M Annett), 59
Model Studies of Elastic Wave Propagations in Crustal Blocks under Tectonic Stresses (Dr. V. S. Tuman), 65
"Modern Aspects of Stereochemistry", Symposium, 1038
Modern Developments in Electron Microscopy (edited by B. M. Siegel), *review* by L. M. Brown, 979
Moffat, J. G., *et al.* : Role of Bradykinin in the Development of Acute Pancreatitis, 1212
Moffett, A., and Ettlinger, Dr. G. : Lateral Preference in the Monkey, 606
Mohiuddin, Prof. A., *et al.* : Possible Explosions in Absorptive Cells of the Jejunum, 1214
Mokoia Carbonaceous Chondrite : 'Impact Contamination' of the (Prof. G. Mueller), 567
Molecular Excitations in Liquid Helium (Prof. L. B. Borst), 870
Molecular Oxygen in Aqueous Systems : Rotation Structure in the Chemiluminescence Spectrum of (Dr. A. U. Khan and Prof. M. Kasha), 241
Molecular Sieving by Cell Membranes of *Bacillus megaterium* (Dr. R. Scherrer and Prof. P. Gerhardt), 649
Molecular Structure of π-allyl-palladium Acetate (Dr. M. R. Churchill and Prof R. Mason), 777
Molecules : Intermolecular Potential Energy Functions for Simple (J. H. Dymond *et al.*), 678
New Cellulose Derivatives for the Isolation of Biologically Active (H. H Weetall and Dr. N. Weliky), 896
Moller, G. : Effect on Tumour Growth in Syngeneic Recipients of Antibodies against Tumour-specific Antigens in Methylcholanthrene-induced Mouse Sarcomas, 846
Molloy, J. O., and Fine, Dr. B. C. : Effects of Insecticide Synergists on Duration of Sleep induced in Mice by Barbiturates, 789
Mollusca : Physiology of, Vol. 1 (edited by K. M. Wilbur and C. M. Yonge), *review* by Dr. W. T. W. Potts, 818
Molluscicidal Activity of Surface-active Agents on the Snail *Biomphalaria sudanica* ; a Vector of Bilharzia (Dr. S. A. Visser), 492
Molluscicide 1-(*p*-Nitrophenyl)-2-amidineurea Hydrochloride (T 72). : A New (J. Venulet and G. O. Schlutz), 900
Molluscs : Active Transport of Alkaline Earth Ions as Physiological Base of the Accumulation of some Radionuclides in Freshwater (O. van der Borght and S. van Puymbroeck) 533
Molomut, Dr. N., *et al.* : Inhibition of a Transplantable Murine Leukæmia by a Lymphocytopenic Virus, 1003
Moloney Virus : Mouse Antibody Production Test for the Assay of the (Dr. E. Klein and Prof. G. Klein), 339
Molybdenum, Niobium and Their Alloys : The Science and Technology of Tungsten, Tantalum, (edited by N. E. Promisel), *review* by Prof. L. W. Derry, 966
Monarda (Labiatae) : Dependency of Pollination on Patterns in (R. W. Scora), 1011
Mongolism : Urinary Excretion of Beta-Amino-Isobutyric Acid and Taurine in (Prof. G. O. Goodman *et al.*), 650
Monkey : Lateral Preferences in the (Dr. G. Ettlinger and A. Moffett), 606
Monocotyledonous Plants : Transfer of Lily Curl Stripe by a Leaf Union Method Applicable to (Prof. F. P. McWhorter and Dr. T. C. Allen, jun.), 604
Monokaryons from Veil Cells of Friut Bodies of *Coprinus lagopus* sensu Buller . Recovery of (J. W. Cowan), 1113
26-Month Oscillation in Atmospheric Properties and the Apparent Solar Diameter (Prof. R. E. Newell), 278
Montmorillonite, Kaolinite and Illite : Far Infra-red Spectra of (Prof. E. E. Angino), 569
Monuments and Buildings of Antiquity in the Near East, 333
Moon : A Case for Convection in the (Dr. G. Fielder), 171
Colour on the (N. W. Scott), 1075
Moore, J. A. (edited by) : Physiology of the Amphibia, *review* by Dr. C. L. Smith, 1022
Moore, Patrick : Astronomy with Binoculars, *review*, 1019
The Flammarion Book of Astronomy, 815
Pictorial Astronomy, *review*, 1019
Moore, Dr. R. M., *et al.* : Toxicity of *Phalaris tuberosa* for Sheep, 542
Moore, Dr. W. R. : Configurational Statistics of Polymeric Chains, *review*, 963
Newer Methods of Polymer Characterization, *review*, 963
The Chemistry of Cationic Polymerization, *review*, 963
Moorhouse, Dr. R. G. : Fundamental Particles, *review*, 979
Moorthy, P. N., and Weiss, Prof. J. J. : Reversible Photochemical Bleaching in Frozen Aqueous Systems at 77°K, 776
Moray, Dr. N., and Arnold, P. : Confirmation of Apparent Genetic Assimilation of Behaviour in *Drosophila melanogaster*, 504

Morelli, C., et *al.* : Magnetic, Gravity and Depth Surveys in the Mediterranean and Red Sea, 1245
Morgan, Prof. W. T. J., et *al.* : Isolation of a Serologically Active, Fucose-containing, Trisaccharide from Human Blood-group Lea Substance, 740
Moultz, Dr. A. R. : Awarded the Scientific Products Foundation for 1964, 1038
Morley, J. S., et *al.* : The Antral Hormone Gastrin, 931
Mornex, Prof. R., and Hermann, Prof. H. : Human Tumours Secreting Catecholamines, *review* by Dr. A. B. Anderson, 613
Moroson, H., and Gregoriades, A. : Sensitive Chemical Actinometer for Ultraviolet Radiation, 676
Morphinization : Reversal of Hormonal Effects as a Result of Chronic (Prof. E. O'F. Walsh et *al.*), 698
"Morphogenesis and Differentiation in Relation to Cellular Fine Structure", symposium, 925
Morphology of Synthetic Fibres ; a Study on Drawn Polyethylene (I. L. Hay and Dr. A. Keller), 862
Morrill, Prof. G. A., et *al.* : Effect of Calcium on Intracellular Sodium and Potassium Concentrations in Plant and Animal Cells, 641
Morris, N. : The Control of Education, *review*, 309
Morrow, T., and McGrath, Dr. W. D. : Identification of Free Radicals in Flash Photolysis, 988
Morton, Dr. W. R. M., et *al.* : Diagnosis of Auto-immunity, 393
Mosaic Membrane Systems : Porosity Mosaics : Auxiliary Electrodes in (Prof. C. W. Carr and Prof. K. Sollner), 878
Mosher, R. L., et *al.* : Production of $C_2O_4^+$ in an Ion-molecule Reaction, 377
Moshier, R. W. : Analytical Chemistry of Niobium and Tantalum, *review* by Prof. J. R. Partington, 511
Mosquito's Vectorial Capacity : Prognosis for Interruption of Malaria Transmission through Assessment of the (C. Garrett-Jones), 1173
Moss Callus : Gametophytic Plants Induced from Single Cells of (M. Ward), 400
Mossel, Dr. D. A. A., et *al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
Motivation, Perception and Attention on Age-related Changes in Short-term Memory : Influence of (J. Inglis), 103
Moudrianakis, E. N., and Beer, Prof. M. : Selective Reagent for the Study of Base Sequence in Nucleic Acids, 685
Mouse Antibody Production Test for the Assay of the Moloney Virus (Dr. E. Klein and Prof. G. Klein), 339
Mouse, Wild House, (*Mus musculus domesticus* Rutty 1772) : Hæmoglobin Types of the (H. Heinecke and M. Wagner), 1099
Movement of the Cerebrospinal Fluid in Human Beings (Dr. G. Di Chiro), 290
Mrak, E. M., and Chichester, C. O. (edited by) : Advances in Food Research, Vol. 12, *review* by Dr. A. M. Copping, 218
Mucopeptide from the Surface of Ehrlich Ascites Tumour Cells : Isolation of a (O. K. Langley and Dr. E. J. Ambrose), 53
Mueller, Prof. G. : 'Impact Contamination' of the Mokoia Carbonaceous Chondrite, 567
Mueller, Prof. I. I. : Introduction to Satellite Geodesy, *review* by D. G. King-Hele, 514
Muirden, J. : Astronomy with Binoculars, *review* by Patrick Moore, 1019
Muller, P. (edited by) : Space Research IV : Proceedings of the International Space Science Symposium, 1963, *review* by D. G. King-Hele, 315
Mulligan, Prof. J. A. : A Study of Bird Song, *review*, 1239
Mullins, Dr. L. J., and Frumento, Dr. A. S. : Potassium-free Effect in Squid Axons, 1312
Multimodal Interneurones of Locust Optic Lobe (Dr. G. A. Horridge), 499
Mundt, Prof. J. O. : Culture Medium proposed for the Isolation of *Streptococcus faecalis, sensu strictu*, 201
Munk, O., and Nielsen, J. G. : Hadal Fish (Bassogigas profundissimus) with a Functional Swimbladder, 594
Murakami, M., and Brown, Prof. K. T. : Early Receptor Potential of the Vertebrate Retina, 736
Murata, K., and Fukuda, Prof. T. : Hepatic Pyrogen and Cortisone-antipyresis in Canine Endotoxin Fever, 690
Murata, S., et *al.* : Uranium Distribution in Drake Passage Waters, 464
Murphy, G. P., et *al.* : Effect of Hypothalamic Stimulation on the Erythropoietic Response in the Rhesus Monkey, 1163
Murray, Dr. K. E., et *al.* : Occurrence of Farnesene in the Natural Coating of Apples, 80
Murray, Prof. M. R., and Lasfargues, Prof. E. Y. : Cell Differentiation and the Primary Lesion in Mouse Mammary Carcinogenesis, 593
Murray, jun., R. F., et *al.* : A New Variant of Transferrin from Greece, 382
Murty, Dr. M. S. : Pleochroism of Orthopyroxenes, 279
Mus musculus domesticus Rutty 1772 : Hæmoglobin Types of the Wild House Mouse (H. Heinecke and M. Wagner), 1099
Muscle : Electron-microscopical Localization of Products from Histochemical Reactions used to detect Cholinesterase in (Dr. R. Miledi), 293
Volume Change accompanying Passive Stretch of Frog (Prof. R. J. Baskin and P. Paolini), 694
Muscle due to Ageing : Structural and Enzymatic Changes in (Dr. A. K. Susheela), 296
Muscle Fibre Sensitivity to Potassium Ion : Action of Enzymatic Inhibitors (Potassium Cyanide and Sodium Fluoride) on (Prof. G. Valette and K. Ozan), 586
Muscle Fibres : Membrane Potential of Electrolyte-depleted (Dr. R. P. Kernan), 83
Muscle Permeability to Aldolase in Several Experimental Atrophies : Increase of (C. Pellegrino and C. Bibbiani), 483
Muscle Stretch : Presynaptic Inhibition induced by (Dr. M. S. Devanandan et *al.*), 996
Museums Journal, 64, No. 2, 1964, 1139
Mushrooms and Other Common Fungi of the San Francisco Bay Region (R. T. and D. B. Orr), *review* by D. A. Reid, 8
Muskett, Prof. A. E. : Synchytrium, *review*, 415
Mussels, *Unio*, of Lake Maggiore, 1960-63 : Manganese-54 Concentration in Fall-out, Water and (P. Gaglione and Prof. O. Ravera), 1215
Mutagenicity of Ionic Polymers and Leukæmogenic Viruses Relative to Nucleic Acids in *Drosophila melanogaster* (Dr. O. G. Fahmy and Dr. M. J. Fahmy), 46
Mutants of *Salmonella typhimurium* induced by 5-Bromodeoxyuridine (G. W. P. Dawson and P. C. McMahon), 1226
Mutants to Study the Electron Transport Pathway of Nitrate Reductase: Use of (G. J. Sorger), 575
Muus, Prof. J., and Vnenchak, J. M. : Isozymes of Salivary Amylase, 283
Mycoplasma : Establishment of a Turkey Flock Free of 'N' Strain (Prof. R. Yamamoto and C. H. Bigland), 1003
Myelin : Lipid-Protein Unit in (Dr. W. L. G. Gent et *al.*), 553
Myeloid Cells from Erythroid Cells : Simple Separation of Rabbit Marrow (Prof. J. W. Archdeacon et *al.*), 996
Myeloma Proteins : Susceptibility to Papain and Trypsin : Heterogeneity of *H* Chains of (Prof. M. D. Poulik and J. Shuster), 577
Myers, D. K., and Levy, L. : Adenosine-triphosphatase and Potassium Retention in X-Irradiated Erythrocytes, 1324
Maccabaean Prize and Medal 1965, 431
McCaffery, Dr. A. J., and Mason, Dr. S. F. : Optical Rotary Power of DNA and of its Complex with Acridine Orange under Streaming Conditions, 468
McCance, I., and Phillis, Dr. J. W. : Discharge Patterns of Elements in Cat Cerebellar Cortex, and their Responses to Iontophoretically Applied Drugs, 844
McClelland, J. D., and Terasaki, Dr. P. I. : Microdroplet Assay of Human Serum Cytotoxins, 998
McCluer, Prof. R. H., et *al.* : Chemical Aspects of Inhibitors of Rho(D) Antibody, 549
Maccoll, Prof. A. : Electronic Structure of Molecules, *review*, 979
McColl, J. D., *et al.*: Inhibition of Synthesis of Acetylecholine by some Esters of Trimethoxybenzoic Acid, 485
MacConaill, Prof. M. A. : Birefringence of the Spermatozoan Tail, 1103
McConkey, Dr. J. W., et *al.* : Forbidden Lines from Atomic Sulphur, 1180
McConnell, Dr. R. B., et *al.* : New Interpretation of the Geology of British Guiana, 115
McCoy, G., et *al.* : Prevention of Cerebral Œdema Induced by Triethyltin in Rabbits by Cortico-steroids, 891
McCoy, N. H. : The Theory of Rings, *review* by Prof. T. A. A. Broadbent, 980
Macdonald, J. R., et *al.* : Virological Technique, *review*, 1023
Macdonald, Dr. K. D. : Preservation of the Heterozygous Diploid Condition in Industrial Micro-organisms, 404
McDonough, Dr. M. W., and Lowy, Dr. J. : Structure of Filaments produced by Re-aggregation of *Salmonella* Flagellin, 125
Macek, K., and Hais, I. M. (edited by) : Paper Chromatography, Vols. 1-3, *review* by Dr. R. Consden, 414
McFadzean, Dr. J. A., *et al.* : Antiviral Agent, A New : 4-Bromo-3-methylisothiazole-5-carboxaldehyde thiosemicarbazone, M and B 7714, 587
McFarland, Prof. L. Z. : Minimal Salt Load required to induce Secretion from the Nasal Salt Glands of Sea Gulls, 1202
McGee, R. X., et *al.* : Distribution and Motions of OH near the Galactic Centre, 30
McGeer, E. G., et *al.*: Effect of Locally Applied Hemicholinium on the Acetylcholine Content of the Caudate Nucleus, 1309
McGeer, P. L., et *al.*: Effect of Locally Applied Hemicholinium on the Acetylcholine Content of the Caudate Nucleus, 1309
McGill, J. I. : Organization within the Central and Centrifugal Fibre Pathways in the Avian Visual System, 395
McGrath, Dr. W. D., and Morrow, T. : Identification of Free Radicals in Flash Photolysis, 988

Macúch, Prof. P., et *al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
McWhorter, Prof. F. P., and Allen, jun., Dr. T. C. : Transfer of Lily Curl Stripe by a Leaf Union Method Applicable to Monocotyledonous Plants, 604

NAD+-Glycohydrolase of Thyroid Homogenates (Dr. M. L. Maayan), 1169
$NbAs_3$ and $ZrAs_2$ Structures : New Representatives of the (Dr. F. Hulliger), 775
Na Concentration Profile in the Renal Medulla : Derivation of the Partial Differential Equations utilized in a Model describing the (Dr. J. L. Shohet and Prof. G. G. Pinter), 689
Na-Nakorn, Dr. S., et *al.* : Hæmoglobin *H* Disease in Thailand : a Genetical Study, 907
Nagata, Dr. T., and Kinoshita, H. : Effect of Release of Compression on Magnetization of Rocks and Assemblies of Magnetic Minerals, 1183
Narcotic Antagonists : Inhibition of Phenylquinone-Induced Writhing by (Dr. R. I. Taber et *al.*), 189
Nardone, L. J., et *al.* : Rocket Optical Observation of a Day-time Aurora, 461
Nasal Salt Glands of Sea Gulls : Minimal Salt Load required to induce Secretion from the (Prof. L. Z. McFarland), 1202
Nasr, A. N. : Lipids in the Skin of Mice Deficient in Essential Fatty Acids, 1305
National Academic Awards : The Council for, 1134 ; Registrar and Secretary appointed, 427
National Academy of Sciences. See under United States.
National Council for Scientific Policy, Brussels, fourth annual Report, 428
National Council for Technological Awards, report for 1963-64, 229
National Health Service, 429
National Institute of Oceanography, Vol. 11 of Collected Reprints, 731
National Parks, 827
National Physical Laboratory and the National Chemical Laboratory, 1037
National Research Council of Canada, 1964 : *Review of the*, 429
National Science Foundation. See under United States
National Union of Teachers : *The Financing of Education*, 22
First Things First, 1145
Natural Rubber Producers' Research Association, 128
Natural Source Material : Isolation of Methylcobalamin from (Dr. K. Lindstrand), 188
Naturalist : A Great Pathologist and (Dr. G. Lapage), 27
Nature of the Normal Lymphocyte Transfer Reaction (Dr. L. Brent and Dr. P. B. Medawar), 90
Nature of Parasitism (W. P. Rogers), *review* by Prof. B. Dawes, 720 ; *review* by Dr. G. Lapage, 1023
Navon, Dr. G., et *al.* : Inactivation of Chymotrypsin in Aqueous Solution by Atomic Hydrogen, 1056
Nearly Diurnal Nutation of the Earth (Dr. R. O. Vicente and Sir Harold Jeffreys), 120
Neary, Dr. G. J., and Savage, Dr. J. R. K. : Oxygen Effect with 14-MeV Neutrons, 197

Nectria galligena, Bres: Rotting of Apples of the Variety 'Bramley's Seedling' by (Dr. T. R. Swinburne), 493
Negative Ion Formation in the Atomic Oxygen-Acetylene Reaction (Dr. W. J. Miller and Dr. A. Fontijn), 679
Nelson, G. A., and Olsen, O. A. : Biotypes of Potato Wart in Newfoundland, 406
Nematode *Panagrolaimus rigidus* (Schneider) : Observations on Sexual Attraction and Copulation in the (D. N. Greet), 96
Nematode-trapping Fungi : Staining Technique for the Examination of (M. A. Faust and Prof. D. Pramer), 94
Nematode-trapping Fungi in the Rhizosphere : Occurrence of (E A. Peterson and H. Katznelson), 1111
Neodymium-pulsed Laser : Quadruple Frequency Multiplication of a 1.06μ (F. M. Johnson), 985
Neonatal Lung Tissue in Mice : Effect of Cigarette-smoke Condensates on Homografts of (Dr. J. A. DiPaolo), 1159
Neonatally Thymectomized Hamsters : Intestinal Crypt Lesions in (Dr. R. C. Hard *et al.*), 455
Neonatally Thymectomized Mice by Injection of Allogeneic Dispersed Thymus Cells : Facilitation of Host Lymphoid Tissue Development in (Dr. E. J. Yunis *et al.*), 850
Neonatally Thymectomized Mice by 'Successful' Rat Thymus Transplantation : Failure to Reconstitute (Dr. E. J. Yunis, Prof. C. Martinez and Prof. R. A. Good), 664
Neostigmine on Plasma Free Fatty Acids : Lowering Effect of (Dr. K. I. Colville, Dr. R. A. Salvador, L. A. Lindsay and Prof. J. J. Burns), 888
Nerve Axons : Release of Adenine Nucleotide from (Prof. A. S. Kuperman *et al.*), 1000
Nerve-Depressant Effect of Local Anæsthetics by Carbon Dioxide : Potentiation of the (Prof. G. A. Condouris and A. Shakalis), 57
Nervous Control of Flight Orientation in a Beetle (A. J. Burton), 1333
Nervous Impulse : The Conduction of the (Prof. A. L. Hodgkin), *review* by Dr. B. Frankenhaeuser, 1238
Nervous System Degenerations of Man : Attempts to Demonstrate a Transmissible Agent in Kuru, Amyotrophic Lateral Sclerosis, and other Sub-acute and Chronic (Dr. D. C. Gajdusek and Dr. C. J. Gibbs, Jun.), 257
Nesmeyanov, A. N. : Selected Works in Organic Chemistry, *review* by Dr. F. G. Mann, 978
Neuraminidase on Human Serum Alkaline Phosphatases : Differential Action of (Dr. J. C. Robinson and J. E. Pierce), 472
Neuronal Network operating Rhythmically through Recurrent Inhibition : Simulation of a (P. Andersen and T. Rudjorn), 289
Neurone Membrane by Barium : Hyperpolarization of a (Dr. S. Nishi and H. Soeda), 761
Neurophysiological Research in Canada : Wellcome Trust Grant for, 24
Neuse, E. W. : Ferrocene-containing Polymers : Polycondensation of Ferrocene with Aldehydes, 179
Neutralizing Antibody Responses of Guinea-pigs to Inactivated Rubella Virus Vaccine (Dr. J. W. Frankel), 655
14-MeV Neutrons : Oxygen Effect with (Dr. G. J. Neary and Dr. J. R. K. Savage), 197
Newcombe, J. F. : Differential Plasma Turbidity as an Index of Platelet Count, 87
Newell, Prof. R. E. : 26-Month Oscillation in Atmospheric Properties and the Apparent Solar Diameter, 278
Newill, Dr. V. A., and Goffman, Dr. W. : Generalization of Epidemic Theory, 225
New Image for Library Services, 1
New Joint American-Australian Astronomy Center (Prof. T. Gold and Prof. H. Messel), 18
New Model of Solar Flares (Prof. P. A. Sturrock and B. Coppi), 61
New Mould D-Amino-acid Oxidase (Dr. I. Chibata, T. Tosa and R. Sano), 684
Newton, Hooke and 'Boyle's Law' (Prof. I. B. Cohen), 618
New Zealand Department of Scientific and Industrial Research, 527
Nesmeyanov, A. N. : Vapour Pressure of the Chemical Elements, *review* by Prof. J. R. Partington, 511
Ng, M. L., *et al.* : Reversal of Hormonal Effects as a Result of Chronic Morphinization, 698
Nicholls, Prof. R. W. : Interpolation of Franck-Condon Factors, 373
Nicholls, Prof. R. W., *et al.* : Laser Excitation of Powdered Solids, 1295
Nickel : Resistance of Tea Plants to Blister Blight in Soils augmented with (Dr. C. S. Venkata Ram), 1227
Nickel Chloride : Annealing Behaviour of Recoil Cobalt-57 Atoms in Hexammine (K. Yoshihara), 1296
Nickel-Iron Thin Films : Fast Flux Reversal in Laminated (Dr. F. B. Humphrey and Dr. H. Clow), 769
Nickel Nucleus : Conservation of Protons in a Stable (Dr. R. Brandt), 271
Nickerson, B. : Distribution of Alkaline Phosphatase in the Malpighian Tubules of the Desert Locust, 499
Nicolo, Georges : L'Électronique dans les Appareils de Contrôle Nucléaire, Tome I, *review* by J. F. Hogg, 8
Nicotiana Hybrids : Scopoletin, Scopolin and Chlorogenic Acid in Tumours of Interspecific (Prof. T. C. Tso *et al.*), 779
Nicotine by Tobacco-feeding Insects : Metabolism of (Dr. L. S. Self *et al.*), 300
Nielsen, J. G., and Munk, O. : Hadal Fish (*Bassogigas profundissimus*) with a Functional Swimbladder, 594
β-Nigerose : Crystalline (Dr. F. Yamauchi and K. Matsuda), 1088
Night Sky in November, 333 ; December, 630 ; January, 1258
Nijenhuis, Dr. L. E., and Gemser-Runia, J. : Xg^a Investigations of the Family of a Child with a Ring X Chromosome, 792
Nilova, V. K., and Sukhanova, K. M. : Synthesis of Nucleic Acids in *Opalina ranarum* Ehrbg., 459
Niobium : Pyrochlore Minerals as a Potential Source of Reactor-grade (J. M. Bakes *et al.*), 867
Niobium and Their Alloys : The Science and Technology of Tungsten, Tantalum, Molybdenum, (edited by N. E. Promisel), *review* by Prof. L. W. Derry, 966
Nishi, Dr. S., and Soeda H. : Hyperpolarization of a Neurone Membrane by Barium, 761
Nishijima, K. : Fundamental Particles, *review* by Dr. R. G. Moorhouse, 979
Nissim, Dr. J. A. : Mechanism of Intestinal Absorption : The Concept of a Spectrum of Intracellular Plasma, 148
Nissim, Dr. J. A., and Hart, S. L. : First Receptor in Intestinal Sugar Transport : the Effect of Phloridzin and of Cetrimide on the Intestinal Absorption of α-D-Glucosamine, L-Glucose and D-Xylose, 51
Nitrate Reductase : Use of Mutants to study the Electron Transport Pathway of (G. J. Sorger), 575
Nitrite Reductase : Identity of *Pseudomonas* Cytochrome Oxidase with *Pseudomonas* (Dr. T. Yamanaka), 253
Nitrogen Balance Experiments : Some Theoretical Considerations (D. S. Miller and P. R. Payne), 480
Nitrogen Fixation in Non-legume Root Nodules : Isotopic Investigations of (Dr. G. Bond), 600
Nitrogen Fixing Capacity of Guar : Hydrocyanic Acid Content and (Dr. O. L. Oke), 405
Nitrogen-increased Shoot/Root Ratios : Mechanism for (Dr. S. R. Wilkinson and Prof. A. J. Ohlrogge), 902
Nitrogen, and of Respiratory Inhibitors, on Ethylene, Production by a Subcellular Fraction from Tomatoes : Effects of (M. Meheriuk and Prof. M. Spencer), 43
Nitrogenous Substances in Plants : Petiole Bleeding Sap in the Examination of the Circulation of (Dr. J. S. Pate *et al.*), 1073
Nitz-Litzow, D., *et al.* : Participation of Rat Liver Nuclei in Movements of Sodium, 888
Niven, jun., Dr. C. F., *et al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
Noades, J., *et al.* : Blood Group Antigen Xg^a in Gibbons, 1322
Xg Blood Groups of Chinese, 1002
Nobel Prize for Chemistry, 922
Nobel Prize for Physics Awarded, 923
Nociceptive Response in Mice and its Selective Antagonism by Aspirin : Rapid Induction by Acetylcholine, Bradykinin and Potassium of a (Dr. H. O. J. Collier *et al.*), 1316
Noctilucent Clouds in the Southern Hemisphere (B. Fogle), 14
Noel, Dr. P., and Minz, Dr. B. : Effect of Rhinencephalic Lesions on Cardiovascular Reactions to Noradrenaline, 82
Noise : Problems of (H. B. Milner), 338
Nolte, Dr. D. J. : Chiasma Frequency and Gregarization in Locusts, 1110
Nonaboronnonachloride (Dr. A. G. Massey and Dr. D. S. Urch), 877
Non-dialysable, Heat-stabile, Hypertensive Substance in the Serum of Rats (Dr. Th. Kenner and Dr. W. Waldhäusl), 581
Non-legume Root Nodules : Isotopic Investigations of Nitrogen Fixation in (Dr. G. Bond), 600
Non-thermal Biological Effects of Laser Beams (Dr. V. T. Tomberg). 868
Noradrenaline : Effect of Rhinencephalic Lesions on Cardiovascular Reactions to (Dr. B. Minz and Dr. P. Noel), 82
Noradrenaline in the 'Immunosympathectomized' Rat : Sources of (Dr. M. Vogt), 1315
Normanbrook, Rt. Hon. Lord : British Institute of Management, *British Business Schools*, 611
Nørrevang, Dr. A. : Choanocytes in the Skin of *Harrimania kupfferi* (Enteropneusta), 398
Norton, Dr. A. C., *et al.* : Electroencephalograph during 'Feigned' Sleep in the Opossum, 162
Nour-Eldin, Dr. F. : Electrophoretic Patterns of Lysed Fibrin formed by Homologous and Heterologous Thrombin, 995
Nuclear Energy in Western Europe : Long-term Role of, 1256
Nuclear Volume and Radiosensitivity of Different Cell Types in Gemmæ of *Marchantia polymorpha* L. : Relationship between (M. W. Miller and Dr. A. H. Sparrow), 596
Nuclear War : British Defence Policy and (E. J. de Kadt), *review*, 1241
Nucleation and Morphology of Chymotrypsinogen Crystals (J. A. Hamilton, J. A. Koutsky and Dr. A. G. Walton), 1085
Nucleic Acid in Intact Living Human Organs : Intravital Fluorescence Microscopy in the Qualitative Evaluation of the Interaction of Acridine Orange with (Dr. M. Sherif), 390
Nucleic Acids : A Selective Reagent for the Study of Base Sequence in (E. N. Moudrianakis and Prof. M. Beer), 685
Nucleic Acids in *Drosophila melanogaster* : Mutagenicity of Ionic Polymers and Leukæmogenic Viruses Relative to (Dr. O. G. Fahmy and Dr. M. J. Fahmy), 46
Nucleic Acids in *Opalina ranarum* Ehrbg. : Synthesis of (V. K. Nilova and K. M. Sukhanova), 459
Nucleolus and Chromosomes : Sequential and Reversible Inhibition of Synthesis of Ribonucleic Acid in the : Effect of Benzamide and Substituted Benzimidazoles on Dipteran Salivary Glands (Dr. J. L. Sirlin and Dr. J. Jacob), 545
Nucleon–Nucleon Interaction (Prof. R. Wilson), *review* by A. E. Taylor, 980
Nucleoprotein Synthesis in the New-born Mouse (Prof. J. H. D. Bryan), 574
Nucleus Cluster Formation in Solid Decompositions : Kinetic Evidence for (Dr. D. A. Young), 281
Nuffield Foundation, The, Report for 1963-64, 631
Nuffield Provincial Hospitals Trust, Sixth Report, 834
Nutation, Nearly Diurnal, of the Earth (Dr. R. O. Vicente and Sir Harold Jeffreys), 120
Nutrition : Proceedings of the Sixth International Congress of (general editors : C. F. Mills and R. Passmore), *review* by Dr. W. R. Aykroyd, 961
Nutrition Society Meeting, 526
Nyholm, Prof. R. S., *et al.* : Seven Co-ordinate Vanadium Complexes with Metal-to-metal Bonds, 871

OAKLEY, K. Page : The Problem of Man's Antiquity, *review* by J. Hawkes, 952
Oat Flakes : Volatile Amines as Components of Toasted (Dr. J. Hrdlička and G. Janíček), 1201
Oat Powdery Mildew : Toxicity of Captan Analogues to (D. V. Richmond *et al.*), 1329
O'Brien, R. J., *et al.* : Seven Co-ordinate Vanadium Complexes with Metal-to-metal Bonds, 871
Observations on Induction of Resistance to Rous Sarcoma Cell Antigens in Hamsters (Dr. R. Radzichovskaja), 393
Observations on Sexual Attraction and Copulation in the Nematode *Panagrolaimus rigidus* (Schneider) (D. N. Greet), 96
Occupational Health Service, 1256
Ocean Swell : Magnetic Variations produced by (K. C. Maclure *et al.*), 1290
Oceanic Animals : Vertical Distribution of Radionuclides as Measured in (Prof. W. G. Pearcy and C. L. Osterberg), 440
Oceanography in Brazil (Dr. R. I. Currie), 1261
Oceanography in the Caribbean and Eastern Atlantic (Dr. T. J. Hart), 434
Odintsova, M. S., *et al.* : Chloroplast Ribosomes, 1090
Œstrogen : Methylhistamine and Histamine in the Urine of Women during the Elaboration of (Prof. J. P. Green *et al.*), 1165
Œstrous Cycle and in Conditions of Ovarian Abnormality : Thyroid Function of Friesian Cows during the (Dr. F. A. Soliman *et al.*), 693
Office Economy by O and M (G. E. Milward and P. H. S. Wroe), *review* by T. H. Hawkins, 977
Office of Health Economics : Financing Medical Research, 130
Ogilvie, Dr. B. M. : Reagin-like Antibodies in Animals Immune to Helminth Parasites, 91
Ogilvie, J. F. : Infra-red Absorption of the Hydroxyl Radical, 572
OH near the Galactic Centre : Distribution and Motions of (J. G. Bolton *et al.*), 30
Ohlrogge, Prof. A. J., and Wilkinson, Dr. S. R. : Mechanism for Nitrogen-increased Shoot/Root Ratios, 902
Oil Port, an International, 1139
Oil Production in Australia, 230

Pfeiffer, Dr. R. A., and Büchner, Dr. T. : Absence of Late Replication of a Human X-Ring Chromosome, 804
Phage T_2 : Sphæroplasts of *E. coli* obtained by the Lytic Enzyme isolated from (D. M. Goldfarb *et al.*), 1331
Phagocytosis : Enzymatic Basis of the Respiratory Stimulation during (Dr. R. H. Cagan and Prof. M. L. Karnovsky), 255
Phalaris tuberosa for Sheep : Toxicity of (Dr. C. H. Gallagher *et al.*), 542
Pharmaceutical Sciences : Advances in, Vol. I (edited by H. S. Bean *et al.*), *review* by Prof. E. Shotton, 1237
Phaseolus vulgaris : Metabolic Fate of 2,4-Dichlorophenoxyacetic Acid in the Stem Tissue of (Dr. E. W. Thomas *et al.*), 884
Phaseolus vulgaris and *Pseudomonas phaseolicola* (Halo Blight of Bean) : Interactions of Peroxidases and Catalases between (Prof. K. Rudolph and Prof. M. A. Stahmann), 474
Phenolic Components in Fruit Proanthocyanidins : Presence of Several (S. Ito and Prof. M. A. Joslyn), 475
Phenolics in Normal and Diseased Fruits and Vegetables (Dr. M. K. Seikel), 337
Phenols : Proton Magnetic Resonance of the Hydrogen Bond in (Dr. G. Pala), 1190
Phenoxyacetic Acids in the Stem Tissue of *Avena sativa* : Metabolic Fate of some Chlorinated (E. W. Thomas *et al.*), 286
Phenoxy Free Radicals : Chlorine Hyperfine Splittings in (B. T. Allen and W. Vanneste), 991
p-Phenylenediaminetetraacetic Acid absorbed in Porous Glass : Photochromism of (J. A. Chopoorian *et al.*), 180
2-Phenylethanol in Cider : Determination of (M. E. Kieser, Dr. A. Pollard, P. M. Stevens and O. G. Tucknott), 887
β-Phenylhydroxylamino-β-methyl-pentane-δ-phenylimine Oxide : Electron Spin Resonance of (Dr. V. S. Griffiths and G. R. Parlett), 69
Phenylquinone-induced Writhing by Narcotic Antagonists : Inhibition of (Dr. R. I. Taber, D. D. Greenhouse and S. Irwin), 189
Phillips, Dr. A. P., and Burrows, Prof. R. B. : Dipyrrylvinyl Pyridines as Trichuricides, 892
Phillips, G. F. : Laboratory Handbook, *review*, 214
Phillips, Dr. I. D. J., and Jones, R. L. : Agar-diffusion Technique for estimating Gibberellin Production by Plant Organs, 497
Phillips, Dr. J. G., *et al.* : Pictorial Astronomy, *review* by Patrick Moore, 1019
Phillips, J. P. : Spectra Structure Correlation, *review* by Dr. L. J. Bellamy, 962
Phillis, Dr. J. W., and McCance, I. : Discharge Patterns of Elements in Cat Cerebellar Cortex, and their Responses to Iontophoretically Applied Drugs, 844
Philosophy of Science : The Delaware Seminar, Vol. 2, 1962-1963 (edited by Bernard Baumrin), *review* by G. Buchdahl, 111
Phloridzin and of Cetrimide on the Intestinal Absorption of α-D-Glucosamine, L-Glucose and D-Xylose : First Receptor in Intestinal Sugar Transport : the Effect of (S. L. Hart and Dr. J. A. Nissim), 51
Phonons and Phonon Interactions (edited by T. A. Bak), *review* by Dr. L. Pincherle, 1123
Phosphate : Rate of Labelling of Mitochondrial Phosphohistidine by Radioactive Inorganic (Prof. E. C. Slater and A. Kemp, jun.), 1268
Phosphate-mediated Dehydrogenation of Alcohol in the Photochemistry of Ferrocyanide in Aqueous Solution (Mrs. M. Shirom and Prof. G. Stein), 778
Phosphoglucomutase Polymorphism in Man (Dr. N. Spencer, D. A. Hopkinson and Prof. H. Harris), 742
Phosphohistidine by Radioactive Inorganic Phosphate : Rate of Labelling of Mitochondrial (Prof. E. C. Slater and A. Kemp, jun.), 1268
Phospholipase *C* on Influenza Virus : Action of (Dr. Hiromichi Mizutani and Hiroko Mizutani), 781
Phosphorus-32 and Carbon-14-labelled Tritolylphosphate with Glass Surfaces : Interaction of (Dr. M. E. Schrader and I. Lerner), 759
Phosphorus in Rabbits during Fracture Healing, with Reference to Parathyroid Activity : Serum Calcium and (Dr. F. A. Soliman and S. Y. S. Hassan), 693
Photochemical Bleaching in Frozen Aqueous Systems at 77°K : Reversible (P. N. Moorthy and Prof. J. J. Weiss), 776
Photochemistry of Ferrocyanide in Aqueous Solution : Phosphate-mediated Dehydrogenation of Alcohol in the (Mrs. M. Shirom and Prof. G. Stein), 778
Photochemistry and Radiation Chemistry of Fluorobenzene in Aqueous and Other Solutions (Dr. I. Loeff, Dr. L. M. Revetti and Prof. G. Stein), 1300
Photochromism of *p*-Phenylenediaminetetraacetic Acid absorbed in Porous Glass (J. A. Chopoorian, Mrs. K. O. Loeffler, W. F. Marzluff and G. H. Dorion), 180
Photodimerization in Crystalline 9-Cyanoanthracene (Dr. B. Stevens, T. Dickinson and R. R. Sharpe), 876
Photodynamic Activity in Polycyclic Compounds : Charge-Transfer Complex Formation, Carcinogenicity and (Dr. S. S. Epstein *et al.*), 750
Photo electrically : On a Possibility of measuring the Einstein-shift (M. Frick), 1076
Photolysis : Identification of Free Radicals in Flash (Dr. G. Herzberg and Dr. D. N. Travis), 988 ; (Dr. W. D. McGrath and T. Morrow), 988
Photolysis of Benzene in *Cyclo*hexane : a Water-soluble Product giving a Positive Thiobarbituric Acid Test (A. B. Wells), 182
Photo-oxidation of Ascorbic Acid and Photoreduction of its Oxidized Forms : Influence of Red and Far-red Light on the (Dr. L. W. Mapson and Dr. T. Swain), 886
Photosensitizing Properties of Dyes and White Pigments (Dr. G. S. Egerton), 1153
Photosynthesis : Evidence for the Participation of Chlorophyll *b* in the Primary Reaction of (B. Rumberg), 860
Intermediary Reactions in the Water-splitting Part of (V. Bültemann *et al.*), 646
Site of Action of Copper in (Prof. N. I. Bishop), 401
Phthalocyanine Dye (Heliogen Blue *SBL*) in Ultrastructures of Vital Dyed Axons of the Crab *Carcinus maenas* : Distribution of (Ja. Ju. Komissarchik and S. V. Levin), 203
Phycoerythrin from *Porphyridium cruentum* treated with *p*-Chloro-mercuribenzoate : Modified (E. Fujimori), 1091
Physics : Mathematical Methods of (Dr. J. Mathews and Dr. R. L. Walker), *review* by Prof. I. N. Sneddon, 970
Physics of Atomic Collisions (Dr. J. B. Hasted), *review* by Prof. H. Edels, 980
Physiological Clock (Dr. E. Bünning), *review* by Dr. H. Kalmus, 411
Physiology of the Amphibia (edited by J. A. Moore), *review* by Dr. C. L. Smith, 1022
Physiology of Diurnal Rhythms (J. E. Harker), *review* by Dr. F. J. Ebling, 817
Physiology of Mollusca, Vol. I (edited by K. M. Wilbur and C. M. Yonge), *review* by Dr. W. T. W. Potts, 818
Physiology of Synapses (Prof. J. C. Eccles), *review* by Prof. A. S. V. Burgen, 412

Phytohæmagglutinin in Tissue Culture of Normal Human Leucocytes : Dose-response Curve of (Dr. A. A. MacKinney, jun.), 1002
Pictorial Astronomy (Dr. D. Alter, Dr. C. H. Cleminshaw and Dr. J. G. Phillips), *review* by Patrick Moore, 1019
Pierce, J. E., and Robinson, Dr. J. C. : Differential Action of Neuraminidase on Human Serum Alkaline Phosphatases, 472
Pierce, T. B., *et al.* : Determination of Carbon in Steels by Measurement of the Prompt γ-Radiation emitted during Proton Bombardment, 571
Pieris brassicae L. : Genetically Controlled Variation in Pteridine Content of (Dr. R. Harmsen), 1111
Pieters, H. P., *et al.* : Semi-automatic Extraction using a Rotary-Extractor, 588
Semi-automatic Transfer of Volatile Liquids to Paper Chromatograms, 485
Pigment Formation by *Acetobacter acetigenum* in a Lactate-buffered Glycerol Medium (Prof. K. Ramamurti and C. P. Jackson), 402
Pigments : Photosensitizing Properties of Dyes and White (Dr. G. S. Egerton), 1153
Pigs : Techniques for the Measurement *in vitro* of Tissue Sensitization in Immunized (D. Allan *et al.*), 895
Pilet, P. E. : Auxin Transport in Roots, 559
Pilpel, Dr. N. : Soap Micelles at the Oil/Water Interface, 378
Pimelic Acid as a By-product of Azelaic Acid Degredation by *Pseudomonas* sp. (E. Janota-Bassalik and Prof. L. D. Wright), 501
Pincherle, Dr. L. : Phonons and Phonon Interactions, *review*, 1123
Pinealoma : Demonstration of Hydroxyindole-*O*-methyl Transferase, Melatonin, and Serotonin in a Metastatic Parenchymatous (Dr. R. J. Wurtman *et al.*), 1323
Pinter, Prof. G. G., and Shohet, Dr. J. L. : Derivation of the Partial Differential Equations utilized in a Model describing the Na Concentration Profile in the Renal Medulla, 689
Pinus thunbergii to Acute γ-Irradiation : Early Response of (J. P. OKunewick *et al.*), 394
Pirelahi, H., and Abdoh, Dr. Y. : Alkaloid Content of Tobacco Seeds, 791
Piricauda Bubak from India (P. R. Rao and D. Rao), 200
Pistorius, C. W. F. T. : New High-pressure Polymorphs of Sodium Bromide and Sodium Iodide, 467
Pisum sativum Identification of a Kinetin-like Substance from Pea Seedlings (P. K. Biswas), 297
Pituitary Hormones : Possible Cause of Electrophoretic and Chromatographic Heterogeneity of (Dr. M. Sluyser), 574
Pituitary Thyrotrophin on the Diglyceride/Triglyceride Interrelationships in Thyroid Tissue : Effect of (Prof. N. Freindel and T. W. Scott), 1313
Placenta : Antigen Barrier of the Mouse (Dr. D. R. S. Kirby *et al.*), 548
Compensatory Growth of Villi in Postmature Human (Z. P. Zhemkova and O. I. Topchieva), 703
Planning for the Development Decade, 107
Plant : Atmosphere System : A Gas-tight Growth Chamber for Investigating Gaseous Nitrogen Changes in the Soil (P. J. Ross *et al.*), 444
Plant Nucleoli : Deoxyribonucleic Acid in (Dr. J. McLeish), 36
Plant Organs : Agar-diffusion Technique for estimating Gibberellin Production by (R. L. Jones and Dr. I. D. J. Phillips), 497
Plant Population and Crop Yield (E. F. I. Baker), 856
Plant Taxonomy : Recent Researches in (edited by Dr. W. B. Turrill), *review* by Dr. E. V. Watson, 311
"Plant Waxes, Cutin and Associated compounds", meeting on, 830
Plant and Animals Cells : Effect of Calcium on Intracellular Sodium and Potassium Concentrations in (Prof. G. A. Morrill *et al.*), 641
Plants : Influence of Serum of Children and Adolescents on the Growth of (Prof. J. Čižková *et al.*), 1010
Influence of Soil Organic Matter on the Entry of Cæsium-137 into (Dr. D. A. Barber), 1326
Oxygen Diffusion from the Roots of Some British Bog (W. Armstrong), 801
Petiole Bleeding Sap in the Examination of the Circulation of Nitrogenous Substances in (Dr. J. S. Pate *et al.*), 1073
Plants of the Scottish Lower Carboniferous, 333
Plants, Production of Maternal-type, through Crosses to Apomictic Species (Dr. L. E. Aalders), 101
Plants, The Life of (E. J. H. Corner), *review* by Prof. R. Good, 958
Plants and Animals : Variability of the Strontium-90 and Cæsium-137 Burden of Native (L. L. Eberhardt), 238
Plaskett, Dr. L. G., and Barnaby, Dr. C. F. : Elucidation of the Biosynthetic Pathway of Thyroidal 3 : 5 : 3′ Triiodothyronine by Means of Isotope Position Experiments, 1271
Plasma : The Concept of a Spectrum of Intracellular : Mechanism of Intestinal Absorption (Dr. J. A. Nissim), 148
Electron Temperature in a Laser-heated (E. Archbold and T. P. Hughes), 670
Force associated with the Temperature Gradient on a Small Particle suspended in a (J. R. Brock), 69
Forward Scattering of Light from a Laboratory (U. Ascoli-Bartoli *et al.*), 672
Plasma Angiotensinase Activity in Human Hypertension (Dr. P. Biron, R. Landesman and Dr. J. C. Hunt), 1096
Plasma Cells and Erythroblasts in Baboons : Reticulo-endothelial Cells as 'Nurses' for (Dr. H. Foy and A. Kondi), 293
Plasma Corticosteroids and Ascorbic Acid Content during Bone Fracture Healing : Adrenal and (A. H. Said), 386
Plasma Cortisol-levels : Effect of Electroconvulsive Therapy on (Dr. J. R. Hodges *et al.*), 754
Plasma Free Fatty Acids : Lowering Effect of Neostigmine on (Dr. K. I. Colville *et al.*), 888
Plasma in Chronic Myelogenous Leukæmia : Abnormal Transport of Vitamin B_{12} in (Dr. C. A. Hall and A. E. Finkler), 1207
Plasma Turbidity as an Index of Platelet Count : Differential (J. F. Newcombe), 87
Plasmids in *Salmonella typhimurium* : Genetics of (Mrs. E. Dubnau and Prof. B. A. D. Stocker), 1112
Platelet Count : Differential Plasma Turbidity as an Index of (J. F. Newcombe), 87
Platinum Electrodes : Some Double-layer Capacity Measurements on (Dr. J. P. Hoare), 71
Platinum Metals by Intermetallic Compound Formation : Poisoning of the Surface of (W. R. Buck, III, and H. Leidheiser, jun.), 177
Pleochroism of Orthopyroxenes (Dr. R. A. Howie), 279 ; (Dr. M. S. Murty), 279
Plesch, P. H. (edited by) : The Chemistry of Cationic Polymerization, *review* by Dr. W. R. Moore, 963
Plough and a Rotavator : Lateral Drag of Chemicals in Soil by a (L. N. Staniland), 503
Plutonium Deposition by Desferrioxamine-B : Prevention of (Dr. V. H. Smith), 899
Pneumococcus Polysaccharide by Induced Enzymes : Degredation of Type XIV (Dr. S. A. Barker, Dr. G. I. Pardoe, Prof. M. Stacey and Dr. J. Hopton), 938
Pobiner, H., *et al.* : Autoxidation of Carbanions in Azoxybenzene, 376
Pogonophora (A. V. Ivanov), *review* by Dr. S. M. Manton, 1020
Poisoning of the Surface of Platinum Metals by Intermetallic Compound Formation (W. R. Buck, III, and H. Leidheiser, jun.), 177
Poisonous Substances used in Agriculture, 1256
Polar Ice Sheets : Radio Echo Sounding of (J. T. Bailey *et al.*), 420
Polar Substances on the Benzene Solution of Cobalt Oleate : Peptizing Action of Some (H. Funakoshi and R. Matuura), 186
Polarization and Albedo (C. R. Nagaraja Rao), 277
Polarizing Factor in *Hydra* : Some Biological and Biochemical Properties of the (G. E. Lesh and A. L. Burnett), 492
Polarography of Quinazoline (H. Lund), 1087
Poliovirus by DEAE 'Sephadex A-25' : Purification of (Dr. D. J. Giron and Dr. A. Heliman), 263
Pollack, S. S., *et al.* : Luminescence of Orthopyroxenes, 1292
Pollard, Dr. A., *et al.* : Determination of 2-Phenylethanol in Cider, 887
Pollination on Patterns in *Monarda* (Labiatae) : Dependency of (R. W. Scora), 1011
Poison, A., and Potgieter, G. M. : Diffusion Constants of Proteins determined by a Multi-unit Analytical Method, 379
Polyamide Layers : Thin-layer Chromatography on : Separation of Fat Antioxidants (Dr. J. W. Copius-Peereboom), 748
Polychaetes from Scotland (*Annals and Magazine of Natural History*, **6**, No. 71, 1963), 525
Polycondensation of Ferrocene with Aldehydes : Ferrocene-containing Polymers (E. W. Neuse), 179
Polycyclic Compounds : Charge-transfer Complex Formation, Carcinogenicity and Photodynamic Activity in (Dr. S. S. Epstein *et al.*), 750
Polyembryony in *Minuria integerrima* (DC) Benth : Somatic Apospory and (Prof. G. L. Davis), 94
Polyethylene : Morphology of Synthetic Fibres ; a Study on Drawn (I. L. Hay and Dr. A. Keller), 862
Polymer Characterization : Newer Methods of (edited by Bacon Ke), *review* by Dr. W. R. Moore, 963
Polymer Research for Industry (W. Heap), 1030
Polymerase : Development of Ribonucleic Acid Polymerase in Cells infected with Encephalomyocarditis Virus and the Synthesis of Single- and Double-stranded RNA by the Isolated (Dr. E. Horton *et al.*), 247
Polymeric Chains : Configurational Statistics of (M. V. Volkenstein), *review* by Dr. W. R. Moore, 963
Polymeric Structure of Mercury tert-Butyl Mercury Mercaptide (Prof. N. R. Kunchur), 468
Polymerization : The Chemistry of Cationic (edited by P. H. Plesch), *review* by Dr. W. R. Moore, 963
Polymorphism in Man : Phosphoglucomutase (Dr. N. Spencer *et al.*), 742
Polymorphs of Sodium Bromide and Sodium Iodide : New High-pressure (C. W. F. T. Pistorius), 467
Polymyxin B2 and Polymyxin E1 : Structures of (Dr. S. Wilkinson and L. A. Lowe), 185, 993
Polypeptide Chains : Tryptophan Modification in (A. Previero *et al.*), 687
Polysaccharide by Induced Enzymes : Degradation of Type XIV *Pneumococcus* (Dr. S. A. Barker *et al.*), 938
Polysaccharide resembling Alginic Acid from a *Pseudomonas* Micro-organism (Dr. A. Linker and Dr. R. S. Jones), 187
Polythene : Growth of Bovine Parainfluenza Virus in Chick Tissues growing on (Dr. S. C. Arya), 807
Ponder, E., and Ponder, R. V. : Chromatographic Identification of Lysins in Normal Tissues and Tumours of Mice, 995
Ponder, R. V., and Ponder, E. : Chromatographic Identification of Lysins in Normal Tissues and Tumours of Mice, 995
Ponec, V., and Knor, Z. : Adsorption of Krypton and Xenon on Evaporated Metal Films, 466
Ponomarenko, V. A., *et al.* : Synthesis of Organosilicon Monomers, *review* by Dr. W. Gerrard, 512, 830
Ponsonby, J. E. B., *et al.* : Rotation Rate of Venus measured by Radar Observations, 1964, 63
Pontryagin, L. S., *et al.* : The Mathematical Theory of Optimal Processes, *review* by Dr. A. T. Fuller, 1124
Poort, Dr. C., and van Venrooy, W. J. W. : Detection of Enzymes in Agar Electropherograms, 684
Popesković, L., *et al.* : Suppression of Experimental Allergic Encephalomyelitis in Rats and Chickens treated with Reserpine, 1101
Pop-outs on Concrete Surfaces, 929
Population Establishment : Some Aspects of Weevil Behaviour affecting (G. Surtees), 500
Population Explosion : Biological Aspects of the (Prof. A. S. Parkes), 320
Pories, Major W. J., *et al.* : Zinc-65 in Human Hair, 490
Porous Glass : Photochromism of *p*-Phenylenediaminetetraacetic Acid absorbed in (J. A. Chopoorian *et al.*), 180
Porphyridium cruentum treated with *p*-Chloro-mercuribenzoate : Modified Phycoerythrin from (E. Fujimori), 1091
Posner, Dr. A. S., *et al.* : Crystal Structure of Hydroxyapatite, 1050
Post-natal Behavioural Effects of Meprobamate injected into the Gravid Rat (Dr. M. Kletzkin, Dr. H. Wojciechowski and Dr. S. Margolin), 1206
Post-natal Development of the Optic Nerve : Effect of Light Deprivation on the (Prof. C. P. Wendell-Smith), 707
Post-neonatal Thymectomy Wasting Syndrome : Pathogenesis of the (Dr. K. R. McIntire *et al.*), 151
Post-traumatic Dystrophy in the Rabbit : Experimental (Dr. P. Kredlet), 538
Potassium Absorption in Carrot Root Tissue Cultures : Sensitivity to Dinitrophenol of (A. G. Smithers and Prof. J. F. Sutcliffe), 1330
Potassium at Low Temperatures in Kidney Cortex Slices of Hibernating Mammals : Uptake of (Prof. J. S. Willis), 691
Potassium Concentrations in Plant and Animal Cells : Effect of Calcium on Intracellular Sodium and (Prof. G. A. Morrill *et al.*), 641
Potassium Cyanide and Sodium Fluoride on Muscle Fibre Sensitivity to Potassium Ion : Action of Enzymatic Inhibitors— (Prof. G. Valette and K. Ozan), 586
Potassium Ethyl Oxalate : Metal Ion Catalysis in the Hydrolysis of (Dr. R. W. Hay and N. J. Walker), 1189
Potassium-free Effect in Squid Axons (Dr. A. S. Frumento and Dr. L. J. Mullins), 1312
Potassium to Lactose in Cows' Milk and its Genetic Basis : Ratio of (J. P. Walsh and Dr. J. A. F. Rook), 353
Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin : Rapid Induction by Acetylcholine, Bradykinin and (Dr. H. O. J. Collier *et al.*), 1316
Potassium Retention in X-irradiated Erythrocytes : Adenosine-triphosphatase and (D. K. Myers and L. Levy), 1324
Potato Wart in Newfoundland : Biotypes of (O. A. Olsen and G. A. Nelson), 406
Potgieter, G. M., and Polson, A. : Diffusion Constants of Proteins determined by a Multi-unit Analytical Method, 379
Potter, Prof. P. E., and Pettijohn, Prof. F. J. : Paleocurrents and Basin Analysis, *review* by Dr. A. Lees, 212
Potts, Dr. W. T. W. : Physiology of Mollusca, Vol. 1, *review*, 818
Poulik, Prof. M. D., and Shuster, J. : Heterogeneity of *H* Chains of Myeloma Proteins : Susceptibility to Papain and Trypsin, 577
Powell, Prof. C. F. : Why Should We Study High Energy Nuclear Physics?, 421
Powell, Prof. L. E., and Pratt, C. : Kinins in the Embryo and Endosperm of *Prunus persica*, 602

Powell, R. G., *et al.*: Metabolic Fate of some Chlorinated Phenoxyacetic Acids in the Stem Tissue of *Avena sativa*, 286
Metabolic Fate of 2,4-Dichlorophenoxyacetic Acid in the Stem Tissue of *Phaseolus vulgaris*, 884
Power, L., *et al.*: Effect of Serum from Normal and Diabetic Subjects on Incorporation of Glucose 1-Carbon-14 into Individual Fatty Acids of Rat Adipose Tissue, 943
Practical Home Gardner (T. R. N. Lothian), second edition, *review* by J. Souster, 419
Pramer, Prof. D., *et al.*: Carbon dioxide dependent Morphogenesis in *Arthrobotrys conoides*, 804
Pramer, Prof. D., and Faust, M. A.: Staining Technique for the Examination of Nematode-trapping Fungi, 94
Prange, jun., A. J., *et al.*: Effect of Altered Thyroid Status on Desmethylimipramine Mortality in Mice, 1204
Pratt, C., and Powell, Prof. L. E.: Kinins in the Embryo and Endosperm of *Prunus persica*, 602
Pratt, Prof. D., *et al.*: Succinate Metabolism in *Salmonella typhimurium*, 1285
Pratt, Dr. R. T. C., and Curzon, Dr. G.: Origin of Urinary Resorcinol Sulphate, 383
Preece, Prof. I. A.: *Obituary* by Dr. A. H. Cook, 1035
Pregnant Golden Hamster (*Mesocricetus auratus* Waterhouse) Cyclical Behavioural Activity in the (M. P. M. Richards), 1327
Prehistory of East Africa, The (S. Cole), *review* by J. Hawkes, 952
Prekeratin: Amino-acid Composition of (Prof. A. G. Matoltsy), 380
Preliminary Investigation of the Influence of Controlled Atmosphere Storage on the Organic Acids of Apples (D. A. Kollas), 758
Prentice, Dr. T. C., *et al.*: Ability of Tamarins to Produce and Respond to Erythropoietin, 1064
Pre-Pickwell Down Age of the Plateau Beds (Upper Devonian) in South Wales (J. R. L. Allen), 364
Prepuberal Rat Testis: TPNH Oxidation by the (N. A. Schor and A. Perez), 790
Preservation of the Heterozygous Diploid Condition in Industrial Micro-organisms (Dr. K. D. Macdonald), 404
Preston, J., *et al.*: The Antral Hormone Gastrin, 931
Preston, Prof. R. D.: The Future of Botany, 12
Prestressed Concrete: Codes of Practice, 332
Presynaptic Inhibition induced by Muscle Stretch (Dr. M. S. Devanandan, R. M. Eccles and T. Yokota), 996
Previero, A., *et al.*: Tryptophan Modification in Polypeptide Chains, 687
Price, R. J., *et al.*: Influence of Structure on Mechanical Properties of Pyrolytic Carbon, 371
Primary Education in Britain, 1145
Primary Lesion in Mouse Mammary Carcinogenesis: Cell Differentiation and the (Prof. E. Y. Lasfargues and Prof. M. R. Murray), 593
Primates: Evolutionary and Genetic Biology of, Vols. 1 and 2, *review* by Sir Solly Zuckerman, 949
Pringle, Dr. C. R.: Inhibition of Multiplication of Foot-and-Mouth Disease Virus by Guanidine Hydrochloride, 1012
Private Foundations in the United States, 1259
Proanthocyanidins: Presence of Several Phenolic Components in Fruit (S. Ito and Prof. M. A. Joslyn), 475
Problem of Empathy: On the (Edith Stein), *review* by F. I. G. Rawlins, 4
Problem of Man's Antiquity, The (K. Page Oakley), *review* by J. Hawkes, 952
Problems of Noise (H. B. Milner), 338
Procedure for the Standardization of Tissue Culture Media (Dr. L. Hayflick, P. Jacobs and F. Perkins), 146
Proceedings of the Sixth International Congress of Nutrition (general editors: C. F. Mills and R. Passmore), *review* by Dr. W. R. Aykroyd, 961
Procter and Gamble, Ltd., 1257
Production of $C_2O_4^+$ in an Ion-molecule Reaction (Dr. J. F. Paulson, F. Dale and R. L. Mosher), 377
Production of Maternal-type Plants through Crosses to Apomictic Species (Dr. L. E. Aalders), 101
Production of *Trypanosoma cruzi* Cysts *in vitro* (Dr. V. Iralu), 486
Production and Uses of Natural Graphite (A. R. Tron), *review* by H. B. Milner, 218
Proflavine to Deoxyribonucleic Acid and Ribonucleic Acid and its Biological Significance: Binding of (Dr. C. Scholtissek and Dr. R. Rott), 39
Progesterone and 6-Chloro-Δ^6-17-Acetoxyprogesterone as Inhibitors of Spermatogenesis in the Rabbit (R. J. Ericsson *et al.*), 261
Prognosis for Interruption of Malaria Transmission through Assessment of the Mosquito's Vectorial Capacity (C. Garrett-Jones), 1173
Progress in the Science and Technology of the Rare Earths, Vol. 1 (edited by LeRoy Eyring), *review* by Prof. D. D. Eley, 1018
Progress in Semiconductors, Vol. 8 (edited by Prof. A. F. Gibson and Prof. R. E. Burgess), *review* by Dr. B. Donovan, 513
Progress in Solid State Chemistry, Vol. 1 (edited by H. Reiss), *review* by Prof. F. G. A. Stone, 719
Prokhorov, Prof. A. M., awarded the Nobel Prize for Physics, 923
Promisel, N. E. (edited by): The Science and Technology of Tungsten, Tantalum, Molybdenum, Niobium and their Alloys, *review* by Prof. L. W. Derry, 966
Promoting Industrial Research in Britain, 307
Propagation of Stress Waves in Liquids (Dr. D. H. Trevena), 768
Prophylactic Agent against Upper Respiratory Infections: 'Viractin': a (Prof. B. E. Leach *et al.*), 788
Protan and Deutan Genes; Recombination between: Data on their Relative Positions in Respect of the G6PD Locus (M. Siniscalco *et al.*), 1062
Protection with 2-β-Aminoethylisothiourea, Glutathione and Serotonin of Mice against Whole-body Irradiation (Dr. J. R. Maisin), 196
Protein by Regenerating Liver Cells: Uptake of (Dr. T. Ghose and S. C. Tso), 1210
Protein Synthesis by Acridine Orange: Inhibition of (Dr. A. V. Zelenin and Mrs. E. A. Liapunova), 45
Protein Synthesis *in vitro*: Influence of Amino-acid Levels on (Dr. B. M. Hanking and Prof. S. Roberts), 1194
Proteins: Are Peptide Antibiotics Small (Dr. M. Bodanszky and Dr. D. Perlman), 840
Proteins determined by a Multi-unit Analytical Method: Diffusion Constants of (A. Polson and G. M. Potgieter), 379
Proteins Low in Aromatic Amino-acids: Chemical Analysis of (Dr. R. M. Howell *et al.*), 1088
Proteolytic Enzymes in Structural Investigations of Wool Keratin: Use of (B. D. Greenwood and Dr. P. T. Speakman), 144
Proterozoic Climate: Palæomagnetic Results from Northern Canada suggesting a Tropical (Dr. W. A. Robertson), 66
Prothero, R. M., and Steel, R. W. (edited by): Geographers and the Tropics, *review* by Prof. L. Dudley Stamp, 510
Proton Bombardment: Determination of Carbon in Steels by Measurement of the Prompt γ-Radiation emitted during (T. B. Pierce *et al.*), 571
Proton Magnetic Resonance of the Hydrogen Bond in Phenols (Dr. G. Pala), 1190
Protons in a Stable Nickel Nucleus: Conservation of (Dr. R. Brandt), 271
Prototheca Growth due to 3-Amino-1,2,4-triazole: Reversal by Histidine of the Inhibition of (Dr. P. J. Casselton), 93
Protozoa: Antigenicity of Trypanosome Nucleic: Evidence that DNA is not coupled to Histone in these (Dr. J. S. Beck and Dr. P. J. Walker), 194
Prunus persica: Kinins in the Embryo and Endosperm of (Prof. L. E. Powell and C. Pratt), 602
Pseudomonas aeruginosa: Metallic Sheen in (Dr. A. H. Wahba), 502
Pseudomonas Cytochrome Oxidase with *Pseudomonas* Nitrite Reductase: Identity of (Dr. T. Yamanaka), 253
Pseudomonas Micro-organism: A Polysaccharide resembling Alginic Acid from a (Dr. A. Linker and Dr. R. S. Jones), 187
Pseudomonas phaseolicola: (Halo Blight of Bean): Interactions of Peroxidases and Catalases between *Phaseolus vulgaris* and (Prof. K. Rudolph and Prof. M. A. Stahmann), 474
Pseudomonas pyocyanea: Synergistic Action of Penicillins and Cephalosporins against (Dr. L. D. Sabath and Prof. E. P. Abraham), 1066
Pseudomonas sp.: Pimelic Acid as a By-product of Azelaic Acid Degradation by (L. Janota-Bassalik and Prof. L. D. Wright), 501
Psychological Performance associated with Changes in Total Body Water: Changes in (R. J. Kerry and Dr. J. E. Orme), 1115
Psychological States in Rats: Variations in the Rate of Induction of Chemical Carcinogenesis according to Differing (Dr. M. R. Anderson), 55
Psychomotor Depression produced by Adrenaline in Mice: Effect of Methylamphetamine on the (Prof. E. Fischer *et al.*), 695
Pteridine Content of *Pieris brassicae* L.: Genetically Controlled Variation in (Dr. R. Harmsen), 1111
Public Health Paper, No. 25, 1256
Public Health and Medical Subjects: *Reports on*, 629
Pulse Radiolysis, symposium, 333
Pulsed Radiolysis of Cyclohexane Solutions: Evidence for Reactions of Electrons (Dr. G. Scholes, M. Simic, Dr. G. E. Adams, Dr. J. W. Boag and B. D Michael), 1187
Puppi, A., *et al.*: Various Cell Types of the Adrenal Medulla, 591
Purification of Algal Cultures with Caffeine (S. W. Bowne, jun.), 801
Purification of Poliovirus by DEAE 'Sephadex A-25' (Dr. D. J. Giron and Dr. A. Heliman), 263
Pyridines as Trichuricides: Dipyrrylvinyl (Dr. A. P. Phillips and R. B. Burrows), 892
Pyridoxal with C-3 Unsubstituted Indoles: Reaction of (Dr. T. A. Scott), 77
Pyrochlore Minerals as a Potential Source of Reactor-grade Niobium (J. M. Bakes, Dr. P. G. Jeffery and J. Sandor), 867
Pyrolytic Carbon: Influence of Structure on Mechanical Properties of (J. C Bokros, R. J. Price and T. A. Trozera), 371
Pyrolytic Reactions: Kinetics of (M. H. Back and Prof. K. J. Laidler), 1143
Pyrophosphatase: Electrophoresis of an Insect Inorganic (Dr. E. N. Lambremont and R. M. Schrader), 883
Pyrophosphate under Primitive Earth Conditions: Synthesis of (Prof. S. L. Miller and M. Parris), 1248
Pyrophyllite Synthesized in Slowly Strained Materials: Orientation of (Dr. W. D. Means and Dr. J. Rogers), 244
Pyrrhotite: Iron-deficient Low-temperature (F. J. Sawkins *et al.*), 175

QUADRUPLE Frequency Multiplication of a 1.06-μ Neodymium-pulsed Laser (F. M. Johnson), 985
Qualitative Estimation of Erythrocyte Catalase by Starch-gel Electrophoresis (Dr. E. Kleihauer and Mrs. G. Brandt), 478
Quantitative Analysis of Clay Mineral Mixtures by X-ray Diffraction (A. A. Theisen and E. Bellis), 1228
Quantitative Genetik (G. E. Hiorth), *review* by Prof. W. Williams, 614
Quantity Equations and System Variation in Electricity (P. Cornelius), 173
Quartzite: Graptolites from the Kashmir Himalayas, also a Note on the Discovery of Fossils in the Muth (Prof. M. R. Sahni and V. J. Gupta), 1081
Quiet Sun, 1964-65: International Years of the (Prof. W. J. G. Beynon), 621
Quinazoline: Polarography of (H. Lund), 1087

RABAN, P., *et al.*: Rose Bengal De-iodination *in vitro*, 885
Rabbit γ-globulin Allotypes (U. Grodecka), 595
Rabjohn, Prof. N. (edited by): Organic Syntheses, Vol. 4, revised edition of Annual Volumes 30-39, *review* by Dr. F. G. Mann, 1127
Rabotti, G. F., and Raine, W. A.: Brain Tumours induced in Hamsters inoculated intracerebrally at Birth with Rous Sarcoma Virus, 898
Race, Dr. R. R., *et al.*: Blood Group Antigen Xg^a in Gibbons, 1322
Xg Blood Groups of Chinese, 1002
Radar Observations, 1964: Rotation Rate of Venus measured by (J. E. B. Ponsonby *et al.*), 63
Radiant Energy for Sterilizing Insects: High-Intensity Flash Discharge as a Source of (D. F. Riordan), 1332
Radiation: 35-Gc/s, 70-Gc/s and 94-Gc/s Cytherean (Prof. C. W. Tolbert and Prof. A. W. Straiton), 1242
Radiation Chemistry of Fluorobenzene in Aqueous and Other Solutions: Photochemistry and (Dr. I. Loeff *et al.*), 1300
Radiation Chimeras: Early Lymphatic Regeneration in Thymectomized (Dr. H. Balner and H. Dersjant), 941
Radiation Dose and Giant Cells in the Surviving Cell Population of Mouse Marrow as Determined by Interference Microscopy: Relationship between (H. Lee and Prof. V. Richards), 656
Radiation, Relative Efficiency of High-LET (Bragg-Peak Lithium Ions) on Normal Rabbit Skin, using Integral Dose as a Basis for Comparison (Dr. G. J. D'Angio *et al.*), 1267
Radioactive Inorganic Phosphate: Rate of Labelling of Mitochondrial Phosphohistidine by (Prof. E. C. Slater and A. Kemp, jun.), 1268
Radioactive Metal Mobilization in Medicine (Prof. A. Catsh), *review* by Dr. H Spencer, 112
Radioactive Strontium Content of Rainfall (Dr. E. Bakács-Polgár and I. Kurcz-Csiky), 1057
Radioactivity in South India: Genetical Research in an Area of High Natural (Prof. H. Grüneberg), 222
Radiochemical Centre, Amersham, 332
Catalogue of radioactive products, 730
Radiocommunications at Very Short Wave-lengths: Meteorological Factors in (Dr. R. L. Smith-Rose), 518
Radiocristallographie: Theorie et Technique de la, third edition (Prof. A. Guinier), *review* by Dame Kathleen Lonsdale, 114
Radio Echo Sounding of Polar Ice Sheets (J. T. Bailey, Dr. S. Evans and Dr. G. de Q. Robin), 420
Radio Echo Sounding through an Ice Shelf (M. E. R. Walford), 317
Radiolabelled Target Cells: Application of Iso-immune Cytolysis using (Dr. A. R. Sanderson), 250

Radiological Protection : Recommendations of the International Commission on (As Amended 1959 and Revised 1962), (ICRP Publication No. 6), *review* by Prof. J. Rotblat, 1024
Use of Whole-body Counters in (J. Vennart), 1041
Radiolysis of Methanol Vapour : Production of Hydrogen in the (Dr. G. M. Meaburn *et al.*), 1301
Radiometric Rock Ages and the Problem of the Southward Continuation of the East Greenland Caledonian Orogeny : Some (Prof. L. R. Wager and Dr. E. I. Hamilton), 1079
Radio Noise : On Intergalactic Gas as a Possible Absorber of Extragalactic (Dr. D. W. Sciama), 767
Radionuclides as Measured in Oceanic Animals : Vertical Distribution of (Prof. W. G. Pearcy and C. L. Osterberg), 440
Radionuclides in Freshwater Molluscs : Active Transport of Alkaline Earth Ions as Physiological Base of the Accumulation of some (O. van der Borght and S. van Puymbroeck), 533
Radio-Protection of Tissue Culture Cells by Sulphydryl Compounds : Factors influencing the (A. J. Vergroesen *et al.*), 246
Radio-Protective Effects of β-Mercaptoethylamine : Influence of Hypothermia on the (Dr. E. Magdon), 484
Radio Refractive Index of the Troposphere : Small-scale Irregularities of the (J. A. Lane), 438
Radiosensitivity of Different Cell Types in Gemmæ of *Marchantia polymorpha* L. : Relationship between Nuclear Volume and (M. W. Miller and Dr. A. H. Sparrow), 596
Radio Sources : Comparison of Radio and Optical Positions of some Identified (R. L. Adgie), 1028
Radio Waves in the Galaxy : Absorption of (Prof. G. R. A. Ellis and P. A. Hamilton), 272
Radio and Optical Positions of some Identified Radio Sources : Comparison of (R. L. Adgie), 1028
Radium-226 in Diet and Human Bone from San Juan, Puerto Rico (N. A. Hallden and Dr. J. H. Harley), 240
Radmanović, B. : Effect of Drugs on the Amount of Substance P in Rabbit Brain, 1205
Radon Content of Rainwater (P. Banerji and Prof. S. D. Chatterjee), 1185
Radzichovskaja, Dr. R. : Observations on Induction of Resistance to Rous Sarcoma Antigens in Hamsters, 393
Rahman, A., *et al.* : Scientific Societies in India, 1250
Rainbow Lizard : The Life of the (Dr. V. A. Harris), *review* by Dr. G. Underwood, 1021
Raine, W. A., and Rabotti, G. F. : Brain Tumours Induced in Hamsters Inoculated Intracerebrally at Birth with Rous Sarcoma Virus, 898
Rainfall : Radioactive Strontium Content of (Dr. E. Bakács-Polgár and I. Kurcz-Csiky), 1057
Rainfall within the Individual Seedling Root Range : Field Technique for the Concentration of (P. H. Hosegood and P. Howland), 1230
Rainwater : Radon Content of (P. Banerji and Prof. S. D. Chatterjee), 1185
Rajagopal, N. R., *et al.* : Scientific Societies in India, 1250
Rajam, Prof. P. C., *et al.* : Separation of Cerebroproteins of Human Brain, 73
Ramamurti, Prof. K., and Jackson, C. P. : Pigment Formation by *Acetobacter acetigenum* in a Lactate-buffered Glycerol Medium, 402
Raman, C. R. V., and Ramanathan, Y. : Interaction between Lower and Upper Tropical Tropospheres, 31
Ramanthan, Y., and Raman, C. R. V. : Interaction between Lower and Upper Tropical Tropospheres, 31
Ramsay Memorial Fellowships Trust, 629
Rand, Dr. H. J., *et al.* : Immunochromatographic Partition of Soluble Antigens on Columns of Insoluble Diazo-gamma-globulins, 265
Random Essays on Mathematics, Education and Computers (J. G. Kemeny), *review* by Prof. T. A. A. Broadbent, 1128
Rankin, J. B., *et al.* : The Glasgow University Exploration Society Expedition to Mingulay, 25
Ranney, Dr. H. M., and Jacobs, A. S. : Simultaneous Occurrence of Hæmoglobins C and Lepore in an Afro-American, 163
Rao, C. R. N. : Polarization and Albedo, 277
Rao, D., and Rao, P. R. : *Piricauda* Bubak from India, 200
Rao, P. R., and Rao, D. : *Piricauda* Bubak from India, 200
Raper, J. H., *et al.* : Lipid-Protein Unit in Myelin, 553
Rare Earths : Progress in the Science and Technology of the, Vol. I (edited by LeRoy Eyring), *review* by Prof. D. D. Eley, 1018
Rashad, M. N., *et al.* : Diagnosis of Auto-immunity, 393
Ratio of Potassium to Lactose in Cows' Milk and its Genetic Basis (J. P. Walsh and Dr. J. A. F. Rook), 353
Rattee, Prof. I. D. : *Discovery or Invention?* (Inaugural Lecture), 1017
Ravera, Prof. O., and Gaglione, P. : Manganese-54 Concentration in Fall-out, Water, and *Unio* Mussels of Lake Maggiore, 1960-63, 1215
Rawlins, F. I. G. : On the Problem of Empathy, *review*, 4
Ray, Dr. M., *et al.* : Dizygotic Twins with XX/XY Chimerism, 191
Reaction of Pyridoxal with C-3 Unsubstituted Indoles (Dr. T. A. Scott), 77
Reactor-grade Niobium : Pyrochlore Minerals as a Potential Source of (J. M. Bakes *et al.*), 867
Reagent, A Selective, for the Study of Base Sequence in Nucleic Acids, (E. N. Moudrianakis and Prof. M. Beer), 685
Reagin-like Antibodies in Animals Immune to Helminth Parasites (Dr. B. M. Ogilvie), 91
Recent Researches in Plant Taxonomy (edited by Dr. W. B. Turrill), *review* by Dr. E. V. Watson, 311
Recent Reviews of Fossil Fishes (Dr. R. J. G. Savage), 735
Receptor Potential : Isolation and Identification of the Intial Peak of the Early (Dr. W. L. Pak and Dr. R. A. Cone), 836
Receptor Potential of the Vertebrate Retina : Early (Dr. R. A. Cone), 736 ; (Prof. K. T. Brown and M. Murakami), 736
Rechnitz, G. A. : Controlled-Potential Analysis, *review* by J. F. C. Tyler, 219
Recombination between Protan and Deutan Genes : Data on their Relative Positions in Respect of the G6PD Locus (M. Siniscalco, G. Filippi and B. Latte), 1062
Recommendations of the International Commission on Radiological Protection (As Amended 1959 and Revised 1962), (ICRP Publication No. 6), *review* by Prof. J. Rotblat, 1024
Red Cell Hæmolysates of Adult Individuals, Heterozygous for Different Rare Abnormal Hæmoglobins : Oxygen Equilibria of (Prof. T. H. J. Huisman and J. M. Schillhorn van Veen), 701
Red Cells : Hæmoglobin : Reversal of Oxidation and Polymerization in Turtle (B. Sullivan and A. Riggs), 1098
Red Ring Disease : Role of Insects as Vectors of (E. A. C. Hagley), 905
Red Sea : Magnetic, Gravity and Depth Surveys in the Mediterranean and (T. D. Allan *et al.*), 1245
Red-shift : Cosmological (Dr. L. M. Stephenson), 1180
Red and Far-red Light on the Photo-oxidation of Ascorbic Acid and Photoreduction of its Oxidized Forms : Influence of (Dr. L. W. Mapson and Dr. T. Swain), 886
Reduction and Re-oxidation of the Disulphide Bonds of Soy Bean Trypsin Inhibitor (R. F. Steiner), 579
Reed, S. J. B. : Composition of the Metallic Phases in some Stone and Stony-Iron Meteorites, 374
Reeves, R. D., *et al.* : Transport Processes in Low-melting Fused Salts, 1188
Rege, V. P., *et al.* : Isolation of a Serologically Active, Fucose-containing, Trisaccharide from Human Blood-group Lea Substance, 740
Regional Organization of Research in Australia and South-east Asia (G. B. Gresford), 532
Régulateurs Naturels de la Croissance Végétale, *review* by Dr. E. C. Humphries, 1240
Reid, A. M., *et al.* : Luminescence of Orthopyroxenes, 1292
Reid, D. A. : Mushrooms and Other Common Fungi of the San Francisco Bay Region, *review*, 8
Reiffsteck, Dr. A., *et al.* : Production of Hydrogen in the Radiolysis of Methanol Vapour, 1301
Reinert, Dr. H. : Urethane Hyperglycæmia and Hypothalamic Activation, 889
Reinterpretation of the Visceral Skeleton of *Acanthodes* (Dr. R. S. Miles), 457
Reiss, H. (edited by) : Progress in Solid State Chemistry, Vol. I, *review* by Prof. F. G. A. Stone, 719
Reith Lectures, 1964, 431
Relationship between Nuclear Volume and Radiosensitivity of Different Cell Types in Gemmæ of *Marchantia polymorpha* L. (M. W. Miller and Dr. A. H. Sparrow), 596
Relationship between Radiation Dose and Giant Cells in the Surviving Cell Population of Mouse Marrow as Determined by Interference Microscopy (H. Lee and Prof. V. Richards), 656
"Relativistic Astrophysics", symposium, 431
Renal Medulla : Derivation of the Partial Differential Equations utilized in a Model describing the Na Concentration Profile in the (Dr. J. L. Shohet and Prof. G. G. Pinter), 689
Renshaw Cells : Location of (Prof. W. D. Willis and J. C. Willis), 1214
Reptilia in Mainland Britain : Introduced Species of Amphibia and, 1146
Resch, G. M., *et al.* : Spaced-site Observations of Jupiter in 1963, 637
Research Councils, 1036
Research for Industry, 1963 (Department of Scientific and Industrial Research), 307, 334
Research in Australia and South-east Asia : Regional Organization of (G. B. Gresford), 532
Research Institute for Consumer Affairs, 1
Reserpine : Suppression of Experimental Allergic Encephalomyelitis in Rats and Chickens treated with (Prof. B. D. Janković *et al.*), 1101
Resorcinol Sulphate : Origin of Urinary (Dr. G. Curzon and Dr. R. T. C. Pratt), 383
Respiratory Infections : 'Viractin' : a Prophylactic Agent against Upper (Prof. B. E. Leach *et al.*), 788
Respiratory Inhibitors, on Ethylene Production by a Sub-cellular Fraction from Tomatoes : Effects of Nitrogen, and of (M. Meheriuk and Prof. M. Spencer), 43
Responsibility and Education, 409
Retention as a Function of Previous Learning (J. M. von Wright and H. Salminen), 301
Reticulocytes transfused into a Normal Rabbit : *In vivo* Maturation of Immature (R. L. Millette and E. R. Glowacki), 1207
Reticulo-endothelial Cells as 'Nurses' for Plasma Cells and Erythroblasts in Baboons (Dr. H. Foy and A. Kondi), 293
Retina : Early Receptor Potential of the Vertebrate (Dr. R. A. Cone), 736 ; (Prof. K. T. Brown and M. Murakami), 736
Retinal Image : Alpha-frequency of Electroencephalogram and a Stabilized (C. R. Evans and Dr. G. K. Smith), 303
Reuter, T. : Formation of Isorhodopsin in the Frog's Eye during Continuous Illumination 784
Reversal by Histidine of the Inhibition of *Prototheca* Growth due to 3-Amino-1,2,4-triazole (Dr. P. J. Casselton), 93
Reversible Photochemical Bleaching in Frozen Aqueous Systems at 77°K (P. N. Moorthy and Prof. J. J. Weiss), 776
Revetti, Dr. L. M., *et al.* : Photochemistry and Radiation Chemistry of Fluorobenzene in Aqueous and Other Solutions, 1300
Review of National and Co-operative International Space Activities, 1964, 1037
Revision of the Classification of the Calcareous Sponges (Dr. M. Burton), *review* by Dr. W. C. Jones, 416
Rheological Research in Britain (Dr. R. Roscoe), 733
Rhesus Monkey : Effects of Hypothalamic Stimulation on the Erythropoietic Response in the (Prof. E. A. Mirand *et al.*), 1163
Rhinencephalic Lesions on Cardiovascular Reactions to Noradrenaline : Effect of (Dr. B. Minz and Dr. P. Noel), 82
Rhinos Belong to Everybody (Dr. B. Grzimek), *review* by Dr. L. Harrison Matthews, 1023
Rhizobial Nitrogen Fixation in African Acacias, 431
Rhizosphere : Occurrence of Nematode-trapping Fungi in the (E. A. Peterson and H. Katznelson), 1111
Rhodnius prolixus (Stal.) : Effects of High Temperature in (A. Y. K. Okasha), 1221
Rhodopseudomonas spheroides : Structure of a Chromatophore Fraction of (Dr. R. Langridge *et al.*), 97
Rhythmic Urinary Excretion of Amphetamine in Man (Dr. A. H. Beckett and M. Rowland), 1203
Ribonucleic Acid by Zone Electrophoresis : An Investigation of Soluble (Dr. E. G. Richards and Dr. W. B. Gratzer), 878
Ribonucleic Acid in the Nucleolus and Chromosomes : Sequential and Reversible Inhibition of Synthesis of : Effect of Benzamide and Substituted Benzimidazoles on Dipteran Salivary Glands (Dr. J. L. Sirlin and Dr. J. Jacob), 545
Ribonucleic Acid Polymerase in Cells infected with Encephalomyocarditis Virus and the Synthesis of Single and Double-stranded RNA by the Isolated Polymerase : Development of (Dr. E. Horton, Dr. S. L. Liu, Dr. L. Dalgarno, Dr. E. M. Martin and Dr. T. S. Work), 247
Ribonucleic Acid to the Action of Actinomycin D. : Resistance of Synthesis of Influenza Virus (Dr. A. G. Bukrinskaya), 205
Ribonucleic Acid and its Biological Significance : Binding of Proflavine to Deoxyribonucleic Acid and (Dr. Scholtissek and Dr. R. Rott), 39
Ribonucleic Acids in Baby Hamster Kidney Cells Infected with Foot-and-Mouth Disease Virus : Virus Specific (Dr. F. Brown and B. Cartwright), 855
Ribosomes : Chloroplast (M. S. Odintsova *et al.*), 1090
Rice : Genetics and Breeding of (Prof. M. F. Chandraratna), *review* by Dr. E. H. Roberts, 217
Rice Plant : Factors affecting the Emergence of Primary Tillers from the True Leaves of the Main Shoot of a (B. A. C. Enyi), 495
Rich Source of Mouse Interferon (N. B. Finter), 1114
Richards, Dr. E. G., and Gratzer, Dr. W. B. : An Investigation of Soluble Ribonucleic Acid by Zone Electrophoresis, 878

Rossi, Prof. B., *et al.* : Two Sources of Cosmic X-rays in Scorpius and Sagittarius, 981
Rossi, Dr. C., *et al.* : Mitochondrial and Cytoplasmic Enzymes for the Reduction of Fumarate to Succinate in Yeast, 167
Rotary-Extractor : Semi-automatic Extraction using a (Prof. R. E. Bailey *et al.*), 588
Rotation Rate of Venus measured by Radar Observations, 1964 (J. E. B. Pettengill, Dr. J. H. Thomson and K. S. Imrie), 63
Rotational Structure in the Chemiluminescence Spectrum of Molecular Oxygen in Aqueous Systems (Dr. A. U. Khan and Prof. M. Kasha), 241
Rotavator : Lateral Drag of Chemicals in Soil by a Plough and (L. N. Staniland), 503
Rotblat, Prof. J. : Recommendations of the International Commission on Radiological Protection (As Amended 1959 and Revised 1962), (ICRP Publication No. 6), *review*, 1024
Scientists' Responsibility in the Atomic Age, 1233
Rothamsted Experiments (D. A. MacLeod), 27
Rothman, Dr. S. S. : Exocrine secretion from the Isolated Rabbit Pancreas, 84
Rott, Dr. R., and Scholtissek, Dr. C. : Binding of Proflavine to Deoxyribonucleic Acid and Ribonucleic Acid and its Biological Significance, 39
Rotting of Apples of the Variety 'Bramley's Seedling' by *Nectria galligena*, Bres (Dr. T. R. Swinburne), 493
Roughage Intake of Housed Sheep : Effect of Time of Year on the (Dr. J. G. Gordon), 798
Rouiller, Ch. (edited by) : The Liver, Vols. I and 2, *review* by Prof. S. Sherlock, 214
Rous Sarcoma Cell Antigens in Hamsters : Observations on Induction of Resistance to (Dr. R. Radzichovskaja), 393
Rous Sarcoma Virus : Brain Tumours induced in Hamsters inoculated intracerebrally at Birth with (G. F. Rabotti and W. A. Raine), 898
Rowe, J. A., *et al.* : Succinate Metabolism in *Salmonella typhimurium*, 1285
Rowett Research Station : Retirement of, and appointment of new Director, 228
Rowland, M., and Becket, Dr. A. H. : Rhythmic Urinary Excretion of Amphetamine in Man, 1203
Royal Aircraft Establishment : Sir Robert Cockburn appointed director, 127
Royal Astronomical Society of Great Britain : Award of Gold Medal, 827
Royal Institute of Technology, Stockholm, 135
Royal Medal awarded to Prof. M. J. Lighthill and Prof. F. W. Brambell, 826, 1129
Royal Scottish Museum, annual Report 1963, 429
Royal Society of Edinburgh : Elections to Council, 626
Royal Society, The (Sir Howard Florey), 1129
Royal Society of London : Award of Royal Medals, 826, 1129
S. G. Brown Medal Awarded, 1254
Election of Officers for 1964, 1035
Films for Hire, 627
Medal Awards, 728
Research Fellowships, 231
Research Professorship, 630
Royal Society of Medicine, Wellcome Trust Grant for the, 1037
Rubber Cultivation : Mineral Deficiencies in, 129
Rubella Virus Vaccine : Neutralizing Antibody Responses of Guinea-Pigs to Inactivated (Dr. J. W. Frankel), 655
Rubidium/Strontium Ages from the Western Transvaal (Dr. H. L. Allsopp), 361
Ruddlesden, S. N. : Special Ceramics, 336
Rudjord, T., and Andersen, P. : Simulation of a Neuronal Network operating Rhythmically through Recurrent Inhibition, 289
Rudolph, Prof. K., and Stahmann, Prof. M. A. : Interactions of Peroxidases and Catalases between *Phaseolus vulgaris* and *Pseudomonas phaseolicola* (Halo Blight of Bean), 474
Rumberg, B. : Evidence for the Participation of Chlorophyll *b* in the Primary Reaction of Photosynthesis, 860
Rumford Medal awarded to Prof. H. C. van du Hulst, 728, 1129
Rumours : Epidemics and (D. J. Daley and Prof. D. G. Kendall), 1118
Runcorn, Prof. S. K. : Changes in the Earth's Moment of Inertia, 823
Rüppel, H., *et al.* : Intermediary Reactions in the Water-splitting Part of Photosynthesis, 646
Rural Life and Urbanized Society (L. Taylor and A. R. Jones, jun.), *review* by H. E. Bracey, 977
Rusk, Hon. Dean : Science and Development in Chile, 915
Russell, Dr. C. R., *et al.* : A Unique Sugar Orthoester, 186
Russell, Dr. I. S., and Ross, Dr. R. B. : Lateralization and One-trial Interhemispheric Transfer of Avoidance Conditioning, 909
Russell, Dr. J. S. : Mathematical Expression of Seasonal Changes in Soil Organic Matter, 161
Ruzička, V., *et al.* : Influence of Serum of Children and Adolescents on the Growth of Plants, 1010
Ryan, Dr. J. W., *et al.* : Role of Bradykinin in the Development of Acute Pancreatitis, 1212
Ryder, Dr. M. L. : Fleece Evolution in Domestic Sheep, 555

SABATH, Dr. L. D., and Abraham, Prof. E. P. : Synergistic Action of Penicillins and Cephalosporins against *Pseudomonas pyocyanea*, 1066
Saccharose and Maltose by Yeasts : Utilization of (J. S. Maria), 781
Sagittarius : Two Sources of Cosmic X-rays in Scorpius and (Prof. R. Giacconi *et al.*), 981
Sahni, Prof. M. R., and Gupta, V. J. : Graptolites from the Kashmir Himalayas, also a Note on the Discovery of Fossils in the Muth Quartzite, 1081
Said, A. H. : Adrenal and Plasma Corticosteroids and Ascorbic Acid Content during Bone Fracture Healing, 386
Salam, Prof. A. awarded the Hughes Medal, 728, 1131
Salicylate, a Powerful Inhibitor of Free Fatty Acid Release (A. Bizzi, A. M. Codegoni and Prof. S. Garattini), 1205
Salisbury, J. W., and Glaser, P. E. (edited by) : Lunar Surface Layer *review* by Prof. Z. Kopal, 974
Salivary Amylase : Isozymes of (Prof. J. Muus and J. M. Vnenchak), 283
Salles, Dr. C. A. : *Blastomyces* (*Paracoccidioides*) *brasiliensis* in Africa, 1211
Salminen, H., and von Wright, J. M. : Retention as a Function of Previous Learning, 301
Salmonella Flagellin : Structure of Filaments produced by Re-aggregation of (Dr. J. Lowy and Dr. M. W. McDonough), 125
Salmonella in Eggs : Use of a Fluorescent Brightener for tracing the Passage of (Dr. A. M. Paton and Prof. J. C. Ayres), 803
Salmonella typhimurium : Genetics of Plasmids in (Mrs. E. Dubnau and Prof. B. A. D. Stocker), 1112
Relationship between Chemical Structure and the Extent of Protection against Ionizing Radiation given by Alcohols to (A. B. Sidle), 597
Succinate Metabolism in (J. A. Rowe *et al.*), 1285
Salmonella typhimurium induced by 5-Bromodeoxyuridine : Mutants of (G. W. P. Dawson and P. C. McMahon), 1226
Salt Load required to induce Secretion from the Nasal Salt Glands of Sea Gulls : Minimal (Prof. L. Z. McFarland), 1202
Saltmarsh-Andrew, M. J., *et al.* : Detection of 'Activated' Compounds on Paper 286
Salts : Transport Processes in Low-melting Fused (Prof. G. J. Janz *et al.*), 1188
Salts in Glasshouse Soils : Simple Estimation of Soluble (D. J. Eagle), 1227
Salvador, Dr. R. A., *et al.* : Lowering Effect of Neostigmine on Plasma Free Fatty Acids, 888
Salzman, Dr. E. W., and Chambers, Dr. D. A. : Inhibition of ADP-induced Platelet Aggregation by Substituted Amino-acids, 698

Samorajski, Dr. T., *et al.* : Environmental Stress and Biological Ageing, 724
Sanders, Dr. F. K. : Viruses of Vertebrates, *review*, 216
Sanders, Dr. J. V. : Colour of Precious Opal, 1151
Sanders, Dr. P. V., *et al.* : Structure of Opal, 990
Sanderson, Dr. A. R. : Applications of Iso-immune Cytolysis using Radiolabelled Target Cells, 250
Sanderson, R. P., *et al.* : Antibody Production by Leucocytes in Peripheral Blood, 1320
Sandor, Dr. G., *et al.* : 7 S Globulin, Immunologically Identical to 19 S Gamma-1 (beta-2)-M-globulin, a New Protein of Horse Serum, 795
Sandor, J., *et al.* : Pyrochlore Minerals as a Potential Source of Reactor-grade Niobium, 867
Sanger, Dr. R., *et al.* : Blood Group Antigen Xg^a in Gibbons, 1322
Sano, R., *et al.* : New Mould D-Amino-acid Oxidase, 684
Saono, S. : Effect of Gibberellic Acid on the Growth and Multiplication of Some Soil Micro-organisms and Unicellular Green Algae, 1328
Sap, Petiole Bleeding, in the Examination of the Circulation of Nitrogenous Substances in Plants (Dr. J. S. Pate *et al.*), 1073
Sapko, P., *et al.* : A New Class of Antimicrobial Agents, 697
Sarcione, Dr. E. J., and Sokal, Prof. J. E. : Failure of Physiological Concentrations of Epinephrine to affect Glycogen-levels in the Isolated Rat Liver, 881
Sarcomas : Effect on Tumour Growth in Syngeneic Recipients of Antibodies against Tumour-specific Antigens in Methylcholanthrene-induced Mouse (G. Möller), 846
Sarjant, Prof. R. J. : The Underground Gasification of Coal, *review*, 969
Sasaki, K., *et al.* : Golgi Cell Inhibition in the Cerebellar Cortex, 1265
Satellite Geodosy : Introduction to (Prof. I. I. Mueller), *review* by D. G. King-Hele, 514
Satellite Signals : Signal Strength Variations of (W. Ireland), 368
Satellites : Ion Gyrofrequency Phenomenon observed in (R. L. Smith *et al.*), 274
Satory, V., *et al.* : Inhibition of a Transplantable Murine Leukæmia by a Lymphocytopenic Virus, 1003
Saturation Characteristics of a Spherical Ionization Chamber and a Determination of Boag's Constant for Air (Dr. T. E. Burlin and S. R. Husain), 670
Saunders, C. P. R., and Latham, Dr. J. : Aggregation of Ice Crystals in Strong Electric Fields, 1293
Saunders, R. A., *et al.* : Meta-stable Ions in Double-focusing Mass Spectrometers. 67
Savage, Dr. J. R. K., and Neary, Dr. G. J. : Oxygen Effect with 14-MeV Neutrons, 197
Savage, Dr. R. J. G. : Recent Reviews of Fossil Fishes, 735
Savage, S. : *Obituary* of Dr. A. H. Uggla, 328
Sawkins, F. J., *et al.* : Iron-deficient Low-temperature Pyrrhotite, 175
Scalella, Dr. P., *et al*, : Interaction of Cytochrome c with Yeast D(-) Lactic Oxidase, 1302
Scandinavian Caledonian Arc System : A Possible Western Continuation of the (I. Hernes), 1186
Scarabaeid Larvae, 525
Scavenging of 'Dissolved' Organic Matter from Seawater with Hydrated Metal Oxides (Dr. P. M. Williams and A. Zirino), 462
Schafer, Dr. R. D. : A Comparison of Free and Bound Amino-acids from Three Tissues of *Cancer antennarius*, 1193
Schapira, F., and Rosa, J. : Lactic Dehydrogenase Isozymes and Ageing of Erythrocytes, 883
Scheinberg, Prof. L., *et al.* : Prevention of Cerebral Œdema induced by Triethyltin in Rabbits by Cortico-steroids, 891
Scherrer, Dr. R., and Gerhardt, Prof. P. : Molecular Sieving by Cell Membranes of *Bacillus megaterium*, 649
Schillhorn van Veen, J. M., and Huisman, Prof. T. H. J. : Oxygen Equilibria of Red Cell Hæmolysates of Adult Individuals, Heterozygous for Different Rare Abnormal Hæmoglobins, 701
Schistosoma mansoni : Humoral Transfer of Protective Factors produced by Irradiated Cercariæ (Dr. A. Perlowagora-Szumlewicz), 1009
Schizaea Spore from the Upper Mesozoic of Kashmir, India : New Species of (N. G. Lukose), 566
Schizophrenia as a Genetic Morphism (Sir Julian Huxley, Prof. E. Mayr, H. Osmond and Prof. A. Hoffer), 220
Schlutz, G. O., and Venulet, J. : New Molluscicide 1-(p-Nitrophenyl)-2-amidineurea Hydrochloride (*T* 72), 900
Schmid, K., *et al.* : Sialic Acid-deficient α_1-Acid Glycoprotein produced in Certain Pathological States, 75
Schneider, C., *et al.* : Rapid Induction by Acetylcholine, Bradykinin and Potassium of a Nociceptive Response in Mice and its Selective Antagonism by Aspirin, 1316
Schneider, H. G., *et al.* : Antiviral Activity of Gliotoxin and Gliotoxin Acetate, 1333
Schneider, J. A., *et al.* : Enzymatic Oxidation of Galactose-6-phosphate, 1304
Scholes, Dr. G., *et al.* : Pulsed Radiolysis of *Cyclo*hexane Solutions : Evidence for Reactions of Electrons, 1187
Scholtissek, Dr. C., and Rott, Dr. R. : Binding of Proflavine to Deoxyribonucleic Acid and Ribonucleic Acid and its Biological Significance, 39
Schools : Scientific Research in (R. H. Dyball), 927
Schor, Dr. N. A., and Perez, A. : TPNH Oxidation by the Prepuberal Rat Testis, 790
Schrader, Dr. M. E., and Lerner, I. : Interaction of Phosphorus-32 and Carbon-14-labelled Tritolylphosphate with Glass Surfaces, 759
Schrader, R. M., and Lambremont, Dr. E. N. : Electrophoresis of an Insect Inorganic Pyrophosphatase, 883
Schram, Dr. A. C., *et al.* : Fatty Acids of Beef Heart Sphingomyelin, 782
Schwartz, Dr. C. M., *et al.* : High-pressure Polymorph of Zirconium Pyrophosphate, 573
Schroedinger and Heisenberg Pictures : Equivalence of the (Dr. H. S. Perlman), 771 ; (Prof. P. A. M. Dirac), 771
Schuiling, Dr. R. D. : The Limestone Assimilation Hypothesis, 1053
Sciama, Dr. D. W. : On Intergalactic Gas as a Possible Absorber of Extra-galactic Radio Noise, 767
Science Council of Japan, Annual Report, 1961-62, 524
Science, Foreign Relations and Government in Developing Nations (S. Gutiérrez-Olivos), 916
Science, Humanism and Libraries (D. J. Foskett), *review* by R. Brightman, 417
Science in Parliament, 1036, 1255
Science, The Role of, in Civilization (R. B. Lindsay), *review* by Dr. S. Toulmin, 1127
Science and Development in Chile (Hon. Dean Rusk), 915
Science and Government Reorganization in Britain, 926
Science and Technology and the New Labour Government, 813
Science and Technology in Relation to Politics, 229
Science and Technology of Tungsten, Tantalum, Molybdenum, Niobium and Their Alloys (edited by N. E. Promisel), *review* by Prof. L. W. Derry, 966
Scientific Apparatus to Schools, Loans of, 729
"Scientific Basis of Maximum Permissible Levels of Radiation Exposure", symposium, 526
Scientific Intellectual, The (L. S. Feuer), *review* by G. Buchdahl, 814
Scientific Man-power and the Next Ten Years, 609
Scientific Products Foundation Award for 1964, 1038
Scientific Research in Schools (R. H. Dyball), 927
Scientific Revolution and World Politics (C. P. Haskins), 507
Scientific Societies in India (A. Rahman, N. Sen and N. R. Rajagopal), 1250
Scientist : Disarmament and the Role of the, 1233
Scientist's Changing Role in World Politics, 507
Scientists' Responsibility in the Atomic Age (Prof. J. Rotblat), 1233
Scintillation-counting Technique for assaying $^{14}CO_2$ in a Warburg Flask : A Simplified (Dr. H. J. Yardley), 281
Sciuridae in Britain : Antibodies to Viruses of the Columbia SK Group in (Dr. A. D. Vizoso and R. Hay), 56
Sclar, Dr. C. B., *et al.* : High-pressure Polymorph of Zirconium Pyrophosphate, 573
Scleroderma : Absence of Kynurenine in Hair of Patients with (Dr. F. Levit), 593
Sclerosis : Attempts to Demonstrate a Transmissible Agent in Kuru, Amyotrophic Lateral Sclerosis, and other Sub-acute and Chronic Nervous System Degenerations of Man (Dr. D. C. Gajdusek and Dr. C. J. Gibbs, jun.), 257
Scopoletin, Scopolin and Chlorogenic Acid in Tumours of Interspecific *Nicotiana* Hybrids (Prof. T. C. Tso, L. G. Burk, L. J. Dieterman and Prof. S. H. Wender), 779
Scopolin and Chlorogenic Acid in Tumours of Interspecific *Nicotiana* Hybrids : Scopoletin, (Prof. T. C. Tso *et al.*), 779
Scora, R. W. : Dependency of Pollination on Patterns in *Monarda* (Labiatae), 1011
Scorpius and Sagittarius : Two Sources of Cosmic X-rays in (Prof. R. Giacconi *et al.*), 981
Scott, Dr. G. B. D., *et al.* : Chemical Analysis of Proteins Low in Aromatic Amino-acids, 1088
Scott, N. W. : Colour on the Moon, 1075
Scott, Dr. T. A. : Reaction of Pyridoxal with C-3 Unsubstituted Indoles, 77
Scott, T. W., and Freinkel, Prof. N. : Effect of Pituitary Thyrotrophin on the Diglyceride/Triglyceride Interrelationships in Thyroid Tissue, 1313
Scurrula on Synthetic Media : Growth of Embryos of *Amyema*, *Amylotheca*, and (Dr. B. M. Johri and Dr. Y. P. Singh Bajaj), 1220
Sea Gulls : Minimal Salt Load required to Induce Secretion from the Nasal Salt Glands of (Prof. L. Z. McFarland), 1202
Sea Urchin Eggs : Percentage Incorporation of Leucine labelled with Carbon-14 into Isolated Mitotic Apparatus during Early Development of (T. Bibring and G. H. Cousineau), 805
Sea Wall at Aberdeen : New, 930
Sea-water with Hydrated Metal Oxides : Scavenging of 'Dissolved' Organic Matter from (Dr. P. M. Williams and A. Zirino), 462
Sea-water, Desalination of, 828
Seal : Chromosomes of the Ring (Dr. P. A. Corfman and Prof. R. M. Richart), 502
Seals (F. T. K. Pentelow), 522
Seals : Locomotion in Antarctic, 430
Seals of the World (J. E. King), *review* by H. R. Hewer, 978
Sedimentary Structures within the Cambrian Succession of the St. Tudwal's Peninsula, South-west Caernarvonshire : Implication of Certain (T. P. Crimes and P. G. Sly), 174
Sedimentation Rate of Cells in Metaphase as compared with Cells in Interphase (Dr. D. A. Arvan, W. H. Erb, jun., and Prof. H. T. Enterline), 1225
Seedling Root Range : Field Technique for the Concentration of Rainfall within the Individual (P. H. Hosegood and P. Howland), 1230
Seedlings of *Striga senegalensis* Benth. : *In vitro* Culture of (S. N. C. Okonkwo), 1108
Seeds, Hardening Treatment of, as a means of increasing Yields under Condition of Inadequate Moisture (Prof. M. Evenari), 1010
Seeds with Ethylmethansulphonate and Diethylsulphate : Treatment of Seeds with (M. L. Belli and T. Cervigni), 1199
Segnit, E. R., *et al.* : Structure of Opal, 990
Seikel, Dr. M. K. : Phenolics in Normal and Diseased Fruits and Vegetables, 337
Selby, F. W., and Walter, Dr. H. : Chemical Reactivity of Avian and Mammalian Hæmoglobins of Different Ages, 1209
Selected Papers on Virology (edited by N. Hahon), *review* by Prof. K. M. Smith, 959
Selected Works in Organic Chemistry (A. N. Nesmeyanov), *review* by Dr. F. G. Mann, 978
Selection of some Strains of *Anopheles atroparvus* with Different Behavioural Responses to Contacts with DDT (J. L. Gerold and J. J. Laarman), 500
Self, Dr. L. S., *et al.* : Metabolism of Nicotine by Tobacco-feeding Insects, 300
'Selfers' and High Mutation Rate during Meiosis in *Ascobolus immersus* (A. Paszewski and S. Surzycki), 809
Sell, Dr. S., *et al.* : Pathogenesis of the Post-Neonatal Thymectomy Wasting Syndrome, 151
Semantic and Acoustic Similarity in Short-term Memory (A. D. Baddeley), 1116
Semi-automatic Extraction using a Rotary-Extractor (Prof. R. E. Bailey, J. H. Beck and H. P. Pieters), 588
Semi-automatic Transfer of Volatile Liquids to Paper Chromatograms (Dr. R. E. Bailey, H. P. Pieters and J. H. Beck), 485
Sen, H. K., *et al.* : Stellar Interiors, *review* by Dr. R. J. Tayler, 972
Sen, N., *et al.* : Scientific Societies in India, 1250
Sensitive Chemical Actinometer for Ultra-violet Radiation (H. Moroson and A. Gregoriades), 676
Sensitivity to Dinitrophenol of Potassium Absorption in Carrot Root Tissue Cultures (A. G. Smithers and Prof. J. F. Sutcliffe), 1330
Sensitization of Anoxic Bacteria to X-rays by Di-t-butyl Nitroxide and Analogues (Dr. P. T. Emmerson and Dr. P. Howard-Flanders), 1005
Separation of Cerebroproteins of Human Brain (Dr. S. Bogoch, Prof. P. C. Rajam and P. C. Belval), 73
Separation of White Blood Cells (Dr. A. Bøyum), 793
Serologically Active, Fucose-containing, Trisaccharide from Human Blood-group Lea Substance : Isolation of a (Y. P. Rege *et al.*), 740
Serotonin in a Metastatic Parenchymatous Pinealoma : Demonstration of Hydroxyindole-O-methyl Transferase, Melatonin, and (Dr. R. J. Wurtman *et al.*), 1323
Serotonin of Mice against Whole-body Irradiation : Protection with 2-β-Aminoethylisothiourea, Glutathione and (Dr. J. R. Maisin), 196
Sertum Anglicum, 1788 (Charles-Louis L'Heritier de Brutelle), *review* by R. D. Meikle, 311
Serum Albumin in the Presence of Congo Red : Paper Electrophoresis of Heat-treated (Prof. S. Tekman and Dr. N. Öner), 287
Serum Alkaline Phosphatases : Differential Action of Neuraminidase on Human (Dr. J. C. Robinson and J. E. Pierce), 472
Serum Angiotensinase : Electrophoretic Behaviour of (Dr. D. Klaus and Dr. P. Biron), 381
Serum Calcium and Phosphorus in Rabbits during Fracture Healing, with Reference to Parathyroid Activity (Dr. F. A. Soliman and S. Y. S. Hassan), 693
Serum Cytotoxins : Microdroplet Assay of Human (Dr. P. I. Terasaki and J. D. McClelland), 998
Serum Enzymes in the Jaundiced Homozygous Gunn Rat (Dr. T. Hargreaves and B. Thom), 1323
Serum from Normal and Diabetic Subjects on Incorporation of Glucose 1-Carbon-14 into Individual Fatty Acids of Rat Adipose Tissue : Effect of (Prof. A. R. Hennes, Dr. K. Awai and L. Power), 943

Serum of Children and Adolescents on the Growth of Plants : Influence of (Prof. J. Čížková, M. Ulrychová and V. Ruzička), 1010
Serum of Rats : A Non-dialysable, Heat-stabile, Hypertensive Substance in the (Dr. Th. Kenner and Dr. W. Waldhäusl), 581
Serum Proteins : Allotypes of Hen (Dr. D. Skalba), 894
Serum- and Liver-cholesterol Concentrations in Chicks : Influence of Basic Antibiotics on (P. De Somer *et al.*), 1306
Seven Co-ordinate Vanadium Complexes with Metal-to-metal Bonds (A. S. Kasenally, Prof. R. S. Nyholm, R. J. O'Brien and Dr. M. H. B. Stiddard), 871
Sewell, G. W. F., and Wilson, J. F. : Occurrence and Dispersal of *Verticillium* Conidia in Xylem Sap of the Hop (*Humulus lupulus* L.), 901
Sex-Chromosome Complement in Man : Abnormalities of the, 23
Sex Chromosomes and Sex Chromatin (Dr. U. Mittwoch), 1032
Sex Ratio in *Calligrapha philadelphica* L. (Coleoptera : Chrysomelidae) : Effect of Supernumerary Chromosomes on (J. G. Robertson), 605
Sex Ratios in Marsupial Pouch Young (G. Caughley and R. I. Kean), 491
Sexual Attraction and Copulation in the Nematode *Panagrolaimus rigidus* (Schneider) : Observations on (D. N. Greet), 96
Shackleton, Lord : Social Organization of Information (Substance of the Presidential Address delivered at the Aslib conference), 1025
Shahani, Prof. K. M., *et al.* : Lysozyme Content of Human Milk, 76
Shakalis, A., and Condouris, Prof. G. A. : Potentiation of the Nerve-Depressant Effect of Local Anæsthetics by Carbon Dioxide, 57
Shape of Small Particles (Dr. C. N. Davies), 104
Shapira, Prof. R., *et al.* : Isolation of a Highly Purified Encephalitogenic Protein from Bovine Cord, 1273
Sharma, B. D., and Tiwari, G. P. : Interdiffusion in Zirconium-Aluminium and Zircaloy-Aluminium System, 178
Sharp, Dr. D. W. A. : Advances in Inorganic Chemistry and Radiochemistry, Vol. 5, *review*, 418
Sharpe, A. G., and Emeléus, H. J. (edited by) : Advances in Inorganic Chemistry and Radiochemistry, Vol. 5, *review* by Dr. D. W. A. Sharp, 418
Sharpe, R. R., *et al.* : Photodimerization in Crystalline 9-Cyanoanthracene, 876
Shasha, B. S., *et al.* : A Unique Sugar Orthoester, 186
Shatter-cone Orientation at Sudbury, Canada (Dr. R. S. Dietz and L. W. Butler), 280
Shawhan, S. D., *et al.* : Ion Gyrofrequency Phenomenon observed in Satellites, 274
Shearer, G. M., *et al.* : Factors affecting the Expansion of the Stem Cell Pool in Transplanted Mouse Bone Marrow, 351
Shechmeister, Prof. I. L., and Parikh, G. C. : Comparative Immunological, Biological and Biophysical Behaviour of Meningopneumonitis Viral Antigenic Preparations, 1013
Sheep : Abnormal Hæmoglobin in (M. Braend *et al.*), 700
Effect of Time of Year on the Roughage Intake of Housed (Dr. J. G. Gordon), 798
Fleece Evolution in Domestic (Dr. M. L. Ryder), 555
Toxicity of *Phalaris tuberosa* for (Dr. C. H. Gallacher *et al.*), 542
Sheppard, Dr. R. C., *et al.* : The Antral Hormone Gastrin, 931
Sherif, Dr. M. : Intravital Fluorescence Microscopy in the Qualitative Evaluation of the Interaction of Acridine Orange with Nucleic Acid in Intact Living Human Organs, 390
Sherlock, Prof. S. : The Liver, Vols. 1 and 2, *review*, 214
Sherman, Prof. J. K. : Unusual Action of Heparin on Ascites Tumour Cells during Freezing and Thawing, 100
Sherpas of Nepal, The (Prof. C. von F. Haimendorf), *review* by Mrs. J. Bourdillon, 510
Shih-Piaw, Prof. C., and Loong-Seng, W. : Absorption Spectra of Silver Vapour, 276
Shirom, Mrs. M., and Stein, Prof. G. : Phosphate-mediated Dehydrogenation of Alcohol in the Photochemistry of Ferrocyanide in Aqueous Solution, 778
Shoalb, K. A., *et al.* : Ionization of Mercury by Alkali Positive Ions, 987
Shock-induced Freezing of 'Activated' Supercooled Water (W. H. Fischer and C. R. Perdue), 764
Shock-inducing Factor in Canine Endotoxin Shock ; Development of (Prof. T. Fukuda, T. Kobayashi and M. Okada), 585
Shohet, Dr. J. L., and Pinter, Prof. G. G. : Derivation of the Partial Differential Equations utilized in a Model describing the Na Concentration Profile in the Renal Medulla, 689
Shoot/Root Ratios : Mechanism for Nitrogen-increased (Dr. S. R. Wilkinson and Prof. A. J. Ohlrogge), 902
Shorrock, J. C., and Grütter, A. : Vapour Pressures of Xenon (77°-180°K) and Krypton (77°-130°K), 1084
Shorrocks, Dr. V. M. : Boron Toxicity in *Hevea brasiliensis*, 599
Short Guide to Geo-Botanical Surveying (S. V. Viktorov, Ye.A. Vostokova and D. D. Vyshivkin), *review* by W. D. Clayton, 419
Shotton, Prof. E. : Advances in Pharmaceutical Sciences, Vol. 1, *review*, 1237
Shrew Genus *Crocidura* in Southern Africa : A Systematic Revision of the (J. Meester), *review* by Dr. G. B. Corbet, 1022
Shrinkage Temperature of Eye Collagen (Dr. H. Stringer and J. Parr), 1307
Shuster, J., and Poulik, Prof. M. D. : Heterogeneity of *H* Chains of Myeloma Proteins : Susceptibility to Papain and Trypsin, 577
Sialic Acid-deficient α_1-Acid Glycoprotein produced in Certain Pathological States (K. Schmid, J. F. Burke, M. Debray-Sachs and K. Tokita), 75

Strontium-89 to Strontium-90 in Precipitation Samples with Sampling Height : Variation in the Ratio of (A. Aarkrog), 771
Strontium-90 and Cæsium-137 in Antarctic Snows (R. N. Woodward), 1291
Strontium-90 and Cæsium-137 Burden of Native Plants and Animals : Variability of the (L. L. Eberhardt), 238
Strontium Content of Rainfall : Radioactive (Dr. E. Bakács-Polgár and I. Kurcz-Csiky), 1057
Structural and Enzymatic Changes in Muscle due to Ageing (Dr. A. K. Susheela), 296
Structure of a Chromatophore Fraction of *Rhodopseudomonas spheroides* (Dr. R. Langridge, P. D. Barron and Dr. W. R. Sistrom), 97
Structure Elucidation of Natural Products by Mass Spectrometry (Dr. H. Budzikiewicz, Dr. C. Djerassi and Dr. D. Williams), Vol. 1, *review* by Dr. J. Harley-Mason, 1237
Structure of Filaments produced by Re-aggregation of *Salmonella* Flagellin (Dr. J. Lowy and Dr. M. W. McDonough), 125
Structure of Glyceraldehyde-3-Phosphate Dehydrogenase (H. C. Watson and Dr. L. J. Banaszak), 918
Structure of Opal (Dr. J. B. Jones, Dr. J. V. Sanders and E. R. Segnit), 990
Structure and Metabolism of Corticosteroids (edited by Jorge R. Pasqualini and Max F. Jayle), *review* by Prof. J. Patterson, 411
Structures of Polymyxin B2 and Polymyxin E1 (Dr. S. Wilkinson and L. A. Lowe), 185, 993
Stuart-Harris, Prof. C. H., and Dickinson, Dr. L. : The Background to Chemotherapy of Virus Diseases, *review* by Sir Christopher Andrewes, 959
Studies of Sensitivity and Electro-kinetic Potential in Leda Clay (E. Penner), 808
Study of Bird Song (E. A. Armstrong), *review* by Prof. J. A. Mulligan, 1239
Study of Fossils (Prof. J. F. Kirkaldy), *review* by Dr. V. A. Eyles, 719
Sturrock, Prof. P. A., and Coppi, B. : New Model of Solar Flares, 61
Sub-cellular Localization of Rat Kidney Alkaline Phosphatase (Dr. M. J. Griffin and Dr. R. P. Cox), 476
Sub-lethal X-ray Damage of Mammalian Cells during Inhibition of Synthesis of Deoxyribonucleic Acid : Recovery from (J. H. Kim, Prof. M. L. Eidinoff and Prof. J. S. Laughlin), 598
Sub-line Differences among C57 Black Mice in Response to Trypan Blue and Outcross (Dr. S. L. Beck), 403
Submicroscopic Ortho- and Patho-Morphology of the Liver (Dr. H. David), *review* by Dr. D. B. Brewer, 1019
Sub-microscopic Structure of Injured Surface of *Paramecium caudatum* (Dr. R. Janisch), 200
Substance P in Rabbit Brain : Effect of Drugs on the Amount of (B. Radmanović), 1205
Sub-units of the Catalase Molecule seen by Electron Microscopy (Dr. R. C. Valentine), 1262
Suba-C., Dr. E. A., and Claus, Dr. G. : Organized Element Distribution in Relation to Size in the Orgueil Meteorite, 118
Succinate in Yeast : Mitochondrial and Cytoplasmic Enzymes for the Reduction of Fumarate to (Dr. C. Rossi *et al.*), 167
Succinate Metabolism in *Salmonella typhimurium* (J. A. Rowe, Prof. D. Pratt and Prof. M. Herzberg), 1285 ; (Prof. M. Herzberg, M. J. Jawad and Prof. D. Pratt), 1285
Sueoka, Prof. N., *et al.* : Synchronous and Dichotomous Replications of the *Bacillus subtilis* Chromosome during Spore Germination, 1069
Sugar Orthoester : A Unique (B. S. Shasha, W. M. Doane, Dr. C. R. Russell and C. E. Rist), 186
Sugimura, Dr. Y., *et al.* : Uranium Distribution in Drake Passage Waters, 464
Suingdumrong, Dr. A., *et al.* : Hæmoglobin *H* Disease in Thailand : a Genetical Study, 907
Sukhanova, K. M., and Nilova, V. K. : Synthesis of Nucleic Acids in *Opalina ranarum* Ehrbg, 459
Sullivan, B., and Riggs, A. : Hæmoglobin : Reversal of Oxidation and Polymerization in Turtle Red Cells, 1098
Sulphur Dioxide as an Air Pollutant, 1257
Sulphydryl Compounds : Factors Influencing the Radioprotection of Tissue Culture Cells by (A. J. Vergroesen *et al.*), 246
Sumner, Dr. W. L. : The Fabulous Isotopes, *review*, 1241
Heat and Thermodynamics, fourth edition, *review*, 418
Personnel and Industrial Psychology, second edition, *review*, 418
South Kensington to Robbins, *review*, 310
Surtees, G. : Some Aspects of Weevil Behaviour affecting Population Establishment, 500
Surzycki, S., and Paszewski, A. : 'Selfers' and High Mutation Rate during Meiosis in *Ascobolus immersus*, 809
Susheela, Dr. A. K. : Structural and Enzymatic Changes in Muscle due to Ageing, 296
Sutcliffe, Prof. J. F., and Smithers, A. G. : Sensitivity to Dinitrophenol of Potassium Absorption in Carrot Root Tissue Cultures, 1330
Svet-Moldavsky, Dr. G. J., and Chernyakhovskaya, I. J. : Destruction of Homologous Cells in Tissue Culture by Nuclei of Immune Lymphocytes, 799
Swain, T., and Mapson, L. W. : Influence of Red and Far-red Light on the Photooxidation of Ascorbic Acid and Photoreduction of its Oxidized Forms, 886
Swallow, Dr. J. C. : Equatorial Undercurrent in the Western Indian Ocean, 436
Swarup, Dr. P., and Kumar, N. : Microwave Faraday Rotation in Ferrite Powders, 947
Swimbladder : A Hadal Fish (*Bassogigas profundissimus*) with a Functional (J. G. Nielsen and O. Munk), 594
Swinburn, Dr. T. R. : Rotting of Apples of the Variety 'Bramley's Seedling' by *Nectria galligena*, Bres, 493
Switching Theory in Space Technology (edited by Prof. H. Aiken and W. F. Main) *review* by G. J. Herring, 1127
Sylvester, J. C. (edited by) : Antimicrobial Agents and Chemotherapy—1963, *review* by Dr. E. P. Abraham, 960
Sylvester Medal awarded to Dr. M. L. Cartwright, 728, 1130
Sympathomimetic Amines by Thyroxine : Exaltation of Toxicity of (Prof. B. N Halpern, C. Drudi-Baracco and D. Bessirard), 387
Symposium on Instrumentation for the Detection and Determination of Pesticides and their Residues in Foods (Residue Reviews, Vol. 5), *review* by H. Egan, 419
Synapses : The Physiology of (Prof. J. C. Eccles), *review* by Prof. A. S. V. Burgen, 412
Syncephalastrum associated with Bovine Mycotic Abortion (Dr. P. D. Turner), 399
Synchronous and Dichotomous Replications of the *Bacillus subtilis* Chromosome during Spore Germination (M. Ofshi, H. Yoshikawa and Prof. N. Sueoka), 1069
Synchytrium (Prof. John S. Karling), *review* by Prof. A. E. Muskett, 415
Synergistic Action of Penicillins and Cephalosporins against *Pseudomonas pyocyanea* (Dr. L. D. Sabath and Prof. E. P. Abraham), 1066
Syngeneic Preference *in vitro* : Demonstration of (K. E. Hellström *et al.*), 661
Syngeneic Recipients of Antibodies against Tumour-specific Antigens in Methylcholanthrene-induced Mouse Sarcomas : Effect on Tumour Growth in (G. Möller), 846
Synthesis of Organosilicon Monomers (A. D. Petrov, B. F. Mironov, V. A. Ponomarenko and E. A. Chernyshev), *review* by Dr. W. Gerrard, 512, 830
Synthesis of Pyrophosphate under Primitive Earth Conditions (Prof. S. L. Miller and M. Parris), 1248
Synthesis and Metabolism of Halothane-1-^{14}C (Dr. R. A. Van Dyke, Prof. M. B. Chenoweth and E. R. Larsen), 471
Synthetic Fibres, Morphology of : A Study on Drawn Polyethylene (I. L. Hay and Dr. A. Keller), 862
Systematic Revision of the Shrew Genus *Crocidura* in Southern Africa (J. Meester), *review* by Dr. G. B. Corbet, 1022

TPNH Oxidation by the Prepuberal Rat Testis (N. A. Schor and A. Perez), 790
Taber, Dr. R. I., *et al.* : Inhibition of Phenylquinone-induced Writhing by Narcotic Antagonists, 189
Tabin, V., and Vyklický, L. : Effect of Amphetamine on Spinal Reflexes, 384
Tamarins to Produce and Respond to Erythropoietin : Ability of (Prof. E. A. Mirand, Dr. T. C. Prentice and Dr. J. T. Grace, jun.), 1064
Tanner, J. M., *et al.* : Human Biology, *review* by Sir Julian Huxley, 950, *erratum*, 1141
Tanno, K., and Asahina, E. : A Large Amount of Trehalose in a Frost-resistant Insect, 1222
Tantalum, Molybdenum, Niobium and their Alloys : The Science and Technology of Tungsten, (edited by N. E. Promisel), *review* by Prof. L. W. Derry, 966
Tapeworm Hexacanth Embryo : Species Specificity of the Immunogenic Complexes of the (Dr. M. A. Gemmell), 705
Tapeworms : Immunological Response to Implanted Adult Dwarf (Prof. R. M. Coleman and L. M. deSa), 397
Tarney, Dr. J., and Evans, Dr. C. R. : Isotopic Ages of Assynt Dykes, 638
Tata, Dr. J. R. : Thalidomide and Induced Amphibian Metamorphosis, 939
Taurine in Mongolism : Urinary Excretion of Beta-Amino-Isobutyric Acid and (Prof. H. O. Goodman *et al.*), 650
Tavolga, W. M. (edited by) : Marine Bio-acoustics : Proceedings of a Symposium held at the Lerner Marine Laboratory, April 1963, *review* by M. J. Tucker, 6
Tayler, Dr. R. J. : Stellar Interiors, *review*, 972
Taylor, A., and Taylor, K. F. : Imprinting to a Static Feature of the Home Environment, 1117
Taylor, A. E. : The Nucleon-Nucleon Interaction, *review*, 980
Taylor, Dr. C. J. : Soviet Progress in Forest Fire Control, *review*, 957
Transplanting Mature Date Palms in Iraq, 835
Taylor, Dr. J. M., *et al.* : Prevention of Cerebral Œdema induced by Triethyltin in Rabbits by Cortico-steroids, 891
Taylor, K. F., and Taylor, A. : Imprinting to a Static Feature of the Home Environment, 1117
Taylor, L., and Jones, jun., A. R. : Rural Life and Urbanized Society, *review* by H. E. Bracey, 977
Tea Plants to Blister Blight in Soils augmented with Nickel : Resistance of (Dr. C. S. Venkata Ram), 1227
"Teachers of Public Health Engineering in Universities and Colleges of Technology", report of a course held, 330
Teaching Machines and Programming (edited by K. Austwick), *review* by J. A. Leonard, 219
Technical Teaching and Instruction (A. Maclennan), *review* by Sir Peter Venables, 975
Technology, Advisory Council on, 922
Tectonic Stresses : Model Studies of Elastic Wave Propagations in Crustal Blocks under (Dr. V. S. Tuman), 65
Tee, D. E. H., *et al.* : Antigenic Properties of Human Tumours, 897
Cryostat Method for the Extraction of Soluble Tissue Components, 682
Type of Antibody Response in Mice Immunized with Transplantable Tumours, 391
Tekman, Prof. S., and Öner, Dr. N. : Paper Electrophoresis of Heat-treated Serum Albumin in the Presence of Congo Red, 287
Telemetry : Galapagos Tortoise and Marine Iguana Deep Body Temperatures measured by Radio (Prof. R. S. Mackay), 355
Temperature Discrimination in the Skin (Prof. A. Iggo), 481
Temperature Gradient on a Small Particle Suspended in a Plasma . Force associated with the (J. R. Brock), 69
Tendon Fibres : Histotopochemistry of Ascorbic Acid in (Dr. F. Bartoš), 1104
Tensors in Electrical Engineering (J. W. Lynn), *review* by Dr. W. J. Gibbs, 112
Tentative Classification of Food Irradiation Processes with Microbiological Objectives (Dr. H. E. Goresline, Dr. M. Ingram, Prof. P. Macúch, Dr. G. Mocquot, Dr. D. A. A. Mossel, Dr. C. F. Niven, jun., and Dr. F. S. Thatcher), 237
Terasaki, Dr. P. I., and McClelland, J. D. : Microdroplet Assay of Human Serum Cytotoxins, 998
Teratogenic Activity of Insulin : Uncouplers of Oxidative Phosphorylation and (Prof. W. Landauer and E. M. Clark), 285
Teratogeny in Vitamin E-deficient Rats : Effect of *d*-Gamma-tocopherol on the Incidence of (Prof. D. W. King), 785
Terminal Distribution in the Superior Colliculus of Fibres Originating in the Visual Cortex (R. D. Lund), 1283
Testis : TPNH Oxidation by the Prepuberal Rat (Dr. N. A. Schor and A. Perez) 790
Tests with Solid Brushes on the Canberra Homopolar Generator (Dr. R. A Marshall), 1079
Testudo elegans Schoepff (Chelonia) : Biomodality of Laying-Hatching Times in (S. D. Jayakar and Dr. H. Spurway), 603

Tetracyanoethylene Complexes as Indicators of the Carbonyl Inductive (—*I*) Effect in Sterically Hindered Aromatic Ketones (C. Wilson, Dr. D. Cohen, Dr. I. T. Millar and Prof. H. D. Springall), 282
Tetracycline by Human Bone *in vitro* : Uptake of (Dr. J. Deleu and Dr. H. Bohr), 1103
Tetracycline in Human Bone-marrow Cultures : Effects of Erythromycin and (Dr. M. R. Vas *et al.*), 1100
Texas Instruments Incorporated, 1963 *Annual Report*, 429
Textile Research in Poland, 24
Thalidomide and Induced Amphibian Metamorphosis (Dr. J. R. Tata), 939
Thatcher, Dr. F. S., *et al.* : Tentative Classification of Food Irradiation Processes with Microbiological Objectives, 237
Theisen, A. A., and Bellis, E. : Quantitative Analysis of Clay Mineral Mixtures by X-ray Diffraction, 1228
"Theoretical and Applied Mechanics", ninth congress, 630
Theorie et Technique de la Radiocristallographie, third edition (Prof. A. Guinier), *review* by Dame Kathleen Lonsdale, 114
Theory of Excitons (R. S. Knox), *review* by R. Loudon, 1024
Theory of Rings, The (N. H. McCoy), *review* by Prof. T. A. A. Broadbent, 980
Thermal Conductivity (R. P. Tye), 636
Thermal Energy : Attenuating Blast Waves produced by an Instantaneous Release of (J. Wadsworth), 673
Thermogenesis and Thyroid Action (R. E. Smith), 1311
Thin-layer Chromatography on Polyamide Layers : Separation of Fat Anti-oxidants (Dr. J. W. Copius-Peereboom), 748
Thiobarbituric Acid Test : a Water-soluble Product giving a Positive : Photo-lysis of Benzene in *Cyclo*hexane (A. B. Wells), 182
Thioethers : Significance of the Solubility of Hydrogen Halides in Mercaptans and (M. J. Frazer and Dr. W. Gerrard), 1299
Thom, B., and Hargreaves, Dr. T. : Serum Enzymes in the Jaundiced Homozygous Gunn Rat, 1323
Thomas, E. W., *et al.* : Metabolic Fate of some Chlorinated Phenoxyacetic Acids in the Stem Tissue of *Avena sativa*, 286
Metabolic Fate of 2,4-Dichlorophenoxyacetic Acid in the Stem Tissue of *Phaseolus vulgaris*, 884
Thomas, Dr. J. J., *et al.* : Urinary Excretion of Beta-Amino-Isobutyric Acid and Taurine in Mongolism, 650
Thomlinson, Dr. J. R., *et al.* : Techniques for the Measurement *in vitro* of Tissue Sensitization in Immunized Pigs, 895
Thompson, A. G., *et al.* : Role of Bradykinin in the Development of Acute Pancreatitis, 1212
Thompson, W. K., and Pethica, B. A. : Water Content of Black Soap Films, 1085
Thomson, Sir George Paget : J. J. Thomson and the Cavendish Laboratory in his Day, *review* by Sir John Cockcroft, 1235
Thomson, Dr. J. H., *et al.* : Rotation Rate of Venus measured by Radar Observations, 1964, 63
Thomson, J. J., and the Cavendish Laboratory in his Day (Sir George Paget Thomson), *review* by Sir John Cockcroft, 1235
Thomson, Sir Landsborough : Birds of Colombia and Adjacent Areas of South and Central America, *review*, 314
Birds of the Labrador Peninsula and Adjacent Areas, *review*, 314
The Waterfowl of the World, Vol. 4, *review*, 114
Thorpe, Dr. W. H. : Social Behaviour and Organization among Vertebrates, *review*, 513
Threlfall, Dr. D. R., *et al.* : Ubiquinone-40 and Vitamin K_2 (40) in *Chromatium vinosum*, 80
Thrombin : Electrophoretic Patterns of Lysed Fibrin formed by Homologous and Heterologous (Dr. F. Nour-Eldin), 995
Thrush, Dr. B. A., and Halstead, C. J. : Chemiluminescent Reactions of SO with O and with O_3, 992
Thymectomized Hamsters : Intestinal Crypt Lesions in Neonatally (Dr. R. C. Hard *et al.*), 455
Thymectomized Mice by 'Successful' Rat Thymus Transplantation : Failure to Reconstitute Neonatally (Dr. E. J. Yunis *et al.*), 664
Thymectomized Radiation Chimeras : Early Lymphatic Regeneration in (Dr. H. Balner and H. Dersjant), 941
Thymectomy Wasting Syndrome : Pathogenesis of the Post-Neonatal (Dr. K. R. McIntire *et al.*), 151
Thymus Cells : Facilitation of Host Lymphoid Tissue Development in Neonatally Thymectomized Mice by Injection of Allogeneic Dispersed (Dr. E. J. Yunis *et al.*), 850
Thymus of a Factor protecting the Skin of the Mouse against the Induction of Skin Cancers induced by 20-Methylcholanthrene : Existence in the (Prof. J. Maisin), 1211
Thymus in Magnesium-deficient Rats : Tumour of the (P. Bois), 1316
Thymus Transplantation : Failure to Reconstitute Neonatally Thymectomized Mice by 'Successful' Rat (Dr. E. J. Yunis *et al.*), 664
Thyroid Action : Thermogenesis and (R. E. Smith), 1311
Thyroid Function of Friesian Cows during the Œstrous Cycle and in Conditions of Ovarian Abnormality (Dr. F. A. Soliman, K. Zaki, M. K. Soliman and M. S. Abdo), 693
Thyroid Homogenates : NAD$^+$-Glycohydrolase of (Dr. M. L. Maayan), 1169
Thyroid Status on Desmethylimipramine Mortality in Mice : Effect of Altered (A. J. Prange, jun., Prof. M. A. Lipton and G. N. Love), 1204
Thyroid Tissue : Effect of Pituitary Thyrotrophin on the Diglyceride/Triglyceride Interrelationships in (Prof. N. Freindel and T. W. Scott), 1313
Thyroidal 3 : 5 : 3′Triiodothyronine by Means of Isotope Position Experiments : Elucidation of the Biosynthetic Path of (Dr. L. G. Plaskett and Dr. C. F. Barnaby), 1271
Thyroxine : Exaltation of Toxicity of Sympathomimetic Amines by (Prof. B. N. Halpern *et al.*), 387
TiAs$_2$-type Phases (Dr. F. Hulliger), 991
Tidal Components in Hurricane Development (D. A. Bradley), 136
Tidal Computations in Rivers and Coastal Waters (J. J. Dronkers), *review* by Dr. R. B. Whittington, 1126
Tigyi, A., *et al.* : Various Cell Types of the Adrenal Medulla, 591
Timiras, Prof. P. S., and Heim, Prof. L. M. : Brain Maturation Measured by Electroshock Seizures in Rats at High Altitude (12,470 ft.; 3,800 m), 1157
Tippett, Dr. P., *et al.* : Blood Group Antigen Xg^a in Gibbons, 1322
Tipson, R. S., and Wolfrom, M. L. (edited by) : Advances in Carbohydrate Chemistry, Vol. 18, *review* by Prof. W. J. Whelan, 412
Tissue Components : Cryostat Method for the Extraction of Soluble (D. E. H. Tee *et al.*), 682
Tissue Culture by Nuclei of Immune Lymphocytes : Destruction of Homologous Cells in (Dr. G. J. Svet-Moldavsky and I. J. Chernyakhovskaya), 799
Tissue Culture Cells by Sulphydryl Compounds : Factors influencing the Radio-Protection of (A. J. Vergroesen *et al.*), 246
Tissue Culture Media : Procedure for the Standardization of (Dr. L. Hayflick *et al.*), 146
Tissue Culture of Normal Human Leucocytes : Dose-response Curve of Phyto-hæmagglutinin in (Dr. A. A. MacKinney, jun.), 1002
Tissue Culture of the Inclusion Blennorrhœa (*LB*4) Strain of the Trachoma-inclusion Conjunctivitis Virus Group : Behaviour in Eggs and (Dr. N. M. Larin and J. D. Treharne), 166
Tissue Cultures on Solid Media (Prof. H. E. Pearson), 198
Tissue Sensitization in Immunized Pigs : Techniques for the Measurement *in vitro* of (D. Allan, Dr. A. Buxton and Dr. J. R. Thomlinson), 895
Tissues : Differences observed between Electron Spin Resonance Signals from Surviving Tumour Tissues and from their Corresponding Normal (Dr. J. W. Mallard and Dr. M. Kent), 1192
Tissues of *Cancer antennarius* : A Comparison of Free and Bound Amino-acids from Three (Dr. R. D. Schafer), 1193
Tissues and Tumours of Mice : Chromatographic Identification of Lysins in Normal (E. Ponder and R. V. Ponder), 995
Titantium Trichloride : Brown (β) : (H. J. Gardner), 282
Tiwari, G. P., and Sharma, B. D. : Interdiffusion in Zirconium-Aluminium and Zircaloy-Aluminium System, 178
Toasted Oat Flakes : Volatile Amines as Components of (Dr. J. Hrdlička and G. Janíček), 1201
Tobacco-feeding Insects : Metabolism of Nicotine by (Dr. L. S. Self *et al.*), 300
Tobacco Seeds : Alkaloid Content of (Dr. Y. Abdoh and H. Pirelahi), 791
Tobacco Tar : Toxicity of Whole (A. Flaks), 592
Tobias, Prof. P. V., and von Koenigswald, Prof. G. H. R. : Comparison between the Olduvai Hominines and those of Java and some Implications for Hominid Phylogeny, 515
Toch, Dr. R., *et al.* : Demonstration of Hydroxyindole-*O*-methyl Transferase, Melatonin, and Serotonin in a Metastatic Parenchymatous Pinealoma, 1323
Todd, W. E. C. : Birds of the Labrador Peninsula and Adjacent Areas, *review* by Sir Landsborough Thomson, 314
Toennies, J. P., and Greene, E. F. : Chemical Reactions in Shock Waves, *review* by Dr. B. P. Levitt, 512
Tokita, K., *et al.* : Sialic Acid-deficient α_1-Acid Glycoprotein produced in Certain Pathological States, 75
Tolbert, Prof. C. W., and Straiton, Prof. A. W. : 35-Gc/s, 70-Gc/s and 94-Gc/s Cytherean Radiation, 1242
Tomato and Growth of *Botrytis cinerea* Pers. : Influence of Fungicides on the (C. L. Lockhart and F. R. Forsyth), 1107
Tomatoes : Effect of Nitrogen, and of Respiratory Inhibitors, on Ethylene Production by a Sub-cellular Fraction from (M. Meheriuk and Prof. M. Spencer), 43
Tomberg, Dr. V. T. : Non-thermal Biological Effects of Laser Beams, 868
Tomita, K., *et al.* : Anthropological Observations of Blood Groups in Hiroshima, 87
Tomkeieff, Prof. S. I. : Hydrogeology, *review*, 961
Topchieva, O. I., and Zhemkova, Z. P : Compensatory Growth of Villi in Post-mature Human Placentae, 703
Torques and Attitude Sensing in Earth Satellites (edited by F. Singer), *review* by W. G. Hughes, 973
Torri, T., *et al.* : Uranium Distribution in Drake Passage Waters, 464
Tortoise, Galapagos, and Marine Iguana Deep Body Temperatures Measured by Radio Telemetry (Prof. R. S. Mackay), 355
Tosa, T., *et al.* : New Mould D-Amino-acid Oxidase, 684
Toulmin, Dr. S. : The Role of Science in Civilization, *review*, 1127
Towards a Common Economic Policy for EEC (PEP Broadsheet No. 481), 525
Townes, Prof. C. H., awarded the Nobel Prize for Physics, 923
Toxicity of Captan Analogues to Oat Powdery Mildew (D. V. Richmond, Dr. E. Somers and C. Zaracovitis), 1329
Toxicity of *Phalaris tuberosa* for Sheep (Dr. C. H. Gallagher, Dr. J. H. Koch, Dr. R. M. Moore and Dr. J. D. Steel), 542
Toxicity of Whole Tobacco Tar (A. Flaks), 592
Trachoma-inclusion Conjunctivitis Virus Group : Behaviour in Eggs and Tissue Culture of the Inclusion Blennorrhœa (*LB*4) Strain of the (Dr. N. M. Larin and J. D. Treharne), 166
Tracy, H. J., *et al.* : The Antral Hormone Gastrin, 931
Traffic Problems and the Countryside, 508
Training within the Organization (D. King), *review* by T. H. Hawkins, 309
Transaminases : Infra-nuclear Distribution of (Dr. K. M. Wang and Prof. T-Y. Wang), 880
Transfer of Lily Curl Stripe by a Leaf Union Method Applicable to Monocotyledonous Plants (Prof. F. P. McWhorter and Dr. T. C. Allen, jun.), 604
Transferrin from Greece : A New Variant of (R. F. Murray, jun., *et al.*), 382
Transferrin Variant in Man : D*Adelaide*—a New (D. W. Cooper *et al.*), 102
Transformation of *Leptospira* (Prof. J. Van Riel), 203
Transplantable Murine Leukæmia by a Lymphocytopenic Virus : Inhibition of a (Dr. N. Molomut, Dr. M. Padnos, L. Gross and V. Satory), 1003
Transplantable Tumours : Type of Antibody Response in Mice immunized with (D. E. H. Tee *et al.*), 391
Transplanted Mouse Bone Marrow : Factors Affecting the Expansion of the Stem Cell Pool in (M. Bennett *et al.*), 351
Transplanting Mature Date Palms in Iraq (Dr. C. J. Taylor), 835
Transplantation : Failure to Reconstitute Neonatally Thymectomized Mice by 'Successful' Rat Thymus (Dr. E. J. Yunis *et al.*), 664
Transplantation Immunity : Role of Debris of Tumour Ascitic Fluid in (Dr. I. Hilgert *et al.*), 704
Transport Processes in Low-melting Fused Salts (Prof. G. J. Janz, R. D. Reeve and A. T. Ward), 1188
Transport and the Community (Prof. C. Buchanan), 509
Travis, Dr. D. N., and Herzberg, Dr. G. : Identification of Free Radicals in Flash Photolysis, 988
Treatment of Seeds with Ethylmethansulphonate and Diethylsulphate (M. L. Belli and T. Cervigni), 1199
Trefall, Prof. H., and Ullaland, S. L. : Long-period Pulsations of Auroral-zone X-rays, 1148
Trehalose in a Frost-resistant Insect : A Large Amount of (E. Asahina and K. Tanno), 1222
Treharne, J. D., and Larin, Dr. N. M. : Behaviour in Eggs and Tissue Culture of the Inclusion Blennorrhœa (*LB*4) Strain of the Trachoma-inclusion Conjunctivitis Virus Group, 166
Trevena, Dr. D. H. : Propagation of Stress Waves in Liquids, 768
Triantaphyllopoulos, Prof. D. C., and Triantaphyllopoulos, Dr. E. : Solubility of Fibrin Clots in Solutions of Heparin, 1096
Triantaphyllopoulos, Dr. E., and Triantaphyllopoulos, Prof. D. C. : Solubility of Fibrin Clots in Solutions of Heparin, 1096
Trichoplusia ni (Hübner) : Methyl Linolenate an Essential Nutrient for the Cabbage Looper (G. M. Chippendale *et al.*), 710
Trichuricides : Dipyrrylvinyl Pyridines as (Dr. A. P. Phillips and Prof. R. B. Burrows), 892
Triethyltin in Rabbits by Cortico-steroids : Prevention of Cerebral Œdema induced by (Dr. J. M. Taylor *et al.*), 891
Trigeminus Reflex in Young Infants (H. C. Hopf, H. J. Hufschmidt and J. Ströder), 1312
Trimethoxybenzoic Acid : Inhibition of Synthesis of Acetylcholine by some Esters of (Dr. S. P. Bhatnagar *et al.*), 485

Trisaccharide from Human Blood-group Lea Substance : Isolation of a Serologically Active, Fucose-containing, (V. P. Rege *et al.*), 740
Tritiated-noradrenaline in the Intact Rat Brain by Imipramine and Structurally Related Compounds : Inhibition of Uptake of (Dr. J. Glowinski and Dr. J. Axelrod), 1318
Tritium Labelling of Antibodies (C. G. Rosén, L. Ehrenberg and G. Ahnström), 796
Tritolylphosphate with Glass Surfaces : Interaction of Phosphorus-32 and Carbon-14-labelled (Dr. M. E. Schrader and I. Lerner), 759
Trobaugh, jun., Prof. F. E., and Lewis, Dr. J. P. : Hæmatopoietic Stem Cells, 589
Tron, A. R. : Production and Uses of Natural Graphite, *review* by H. B. Milner, 218
Trophic Disturbances on Skeletal Muscle Innervation : Influence of (Dr. E. L. M. J. Wiertz-Hoessels), 540
Trophic Level Effect on the Accumulation of Cæsium-137 in Cougars feeding on Mule Deer (R. C. Pendleton, R. D. Lloyd, C. M. Mays and B. W. Church), 708
Trophocyte of *Bombus* : Occurrence of Microvilli and Micropinocytosis in (C. R. Hopkins and Dr. P. E. King), 298
Tropical Medicine (*The Practitioner*, 199, 1964), 1037
Tropical Products Institute, 134
Tropical Proterozoic Climate : Palæomagnetic Results from Northern Canada suggesting a (Dr. W. A. Robertson), 66
Troposphere : Small-scale Irregularities of the Radio Refractive Index of the (J. A. Lane), 438
Tropospheres : Interaction between Lower and Upper Tropical (C. R. V. Raman and Y. Ramanathan), 31
Trozera, T. A., *et al.* : Influence of Structure on Mechanical Properties of Pyrolytic Carbon, 371
Trypan Blue and Outcross : Sub-line Differences among C57 Black Mice in Response to (Dr. S. L. Beck), 403
Trypanosoma cruzi Cysts *in vitro* : Production of (Dr. V. Iralu), 486
Trypanosome Nuclei : Antigenicity of : Evidence that DNA is not coupled to Histone in these Protozoa (Dr. J. S. Beck and Dr. P. J. Walker), 194
Trypsin : Heterogeneity of *H* Chain of Myeloma Proteins : Susceptibility to Papain and (Prof. M. D. Poulik and J. Shuster), 577
Trypsin Inhibitor : Reduction and Re-oxidation of the Disulphide Bonds of Soy Bean (R. F. Steiner), 579
Tryptophan Modification in Polypeptide Chains (A. Previero, A. Signor and S. Bezzi), 687
D-Tryptophan on *E. coli* : Action of (M. Hatanaka), 202
Tso, S. C., and Ghose, Dr. T. : Uptake of Protein by Regenerating Liver Cells, 1210
Tso, Prof. T. C., *et al.* : Scopoletin, Scopolin and Chlorogenic Acid in Tumours of Interspecific *Nicotiana* Hybrids, 779
Tsuchiya, T., *et al.*: Anthropological Observations of Blood Groups in Hiroshima, 87
Tucker, M. J. : Marine Bio-acoustics : Proceedings of a Symposium held at the Lerner Marine Laboratory, April 1963, *review*, 6
Tucknott, O. G., *et al.* : Determination of 2-Phenylethanol in Cider, 887
Tuffrey, Mrs. M. A., and Batchelor, Dr. J. R. : Tumour Specific Immunity against Murine Epitheliomas induced with 9,10-Dimethyl-1,2-Benzanthracene, 349
Tuman, Dr. V. S. : Model Studies of Elastic Wave Propagations in Crustal Blocks under Tectonic Stresses, 65
Speculation on the Origin and Non-symmetry of Two Thin Layers *D″* and *F* Embracing the Liquid Core inside the Earth, 1146
Tumour Ascitic Fluid in Transplantation Immunity : Role of Debris of (Dr. I. Hilgert, A. Castermans, G. Lejeune and M. Vranken), 704
Tumour Growth in Syngeneic Recipients of Antibodies against Tumour-specific Antigens in Methylcholanthrene-induced Mouse Sarcomas : Effect on (G. Möller), 846
Tumour of the Thymus in Magnesium-deficient Rats (P. Bois), 1316
Tumour Specific Immunity against Murine Epitheliomas Induced with 9, 10-Dimethyl-1,2-Benzanthracene (Mrs. M. A. Tuffrey and Dr. J. R. Batchelor), 349
Tumour Tissues and from their Corresponding Normal Tissues : Differences observed between Electron Spin Resonance Signals from Surviving (Dr. J. R. Mallard and Dr. M. Kent), 1192
Tumours : Antigenic Properties of Human (D. E. H. Tee *et al.*), 897
Tumours of Interspecific *Nicotiana* Hybrids : Scopoletin, Scopolin and Chlorogenic Acid in (Prof. T. C. Tso *et al.*), 779
Tumours of the Kidney and Ureter (edited by Sir Eric Riches), *review* by J. D. Fergusson, 1241
Tumours in Mice : An Unidentified Virus which causes the Rapid Production of (J. J. Harvey), 1104
Tumours of Mice : Chromatographic Identification of Lysins in Normal Tissues and (E. Ponder and R. V. Ponder), 995
Tumours Secreting Catecholamines : Human (Prof. H. Hermann and Prof. R. Mornex), *review* by Dr. A. B. Anderson, 613
Tumours : Type of Antibody Response in Mice Immunized with Transplantable (D. E. H. Tee *et al.*), 391
Tungsten, Tantalum, Molybdenum, Niobium and Their Alloys : The Science and Technology of (edited by N. E. Promisel), *review* by Prof. L. W. Derry, 966
Turkey Flock Free of 'N' Strain *Mycoplasma* : Establishment of a (Prof. R. Yamamoto and C. H. Bigland), 1003
Turner, Dr. P. D. : *Syncephalastrum* associated with Bovine Mycotic Abortion, 399
Turril, Dr. W. B. : Recent Researches in Plant Taxonomy, *review* by Dr. E. V. Watson, 311
Turtle Red Cells : Hæmoglobin : Reversal of Oxidation and Polymerization in (B. Sullivan and A. Riggs), 1098
Two Sources of Cosmic X-rays in Scorpius and Sagittarius (Prof. R. Giacconi, Dr. H. Gursky, J. R. Waters, Prof. G. Clark and Prof. B. Rossi), 981
Tye, R. P. : Thermal Conductivity, 636
Tyler, J. F. C. : Controlled-Potential Analysis, *review*, 219
Tyloses : Fine Structure of (R. C. Foster), 494
Tyutyunov, I. A. : An Introduction to the Theory of the Formation of Frozen Rocks, *review* by Dr. E. I. Hamilton, 816

Ubbelohde, Prof. A. R. J. P., elected a corresponding member of the Göttingen Akademie der Wissenschaften, 231
Melting and Freezing, 1046
Ubiquinone-40 and Vitamin K_2 (40) in *Chromatium vinosum* (L. K. Osnitskaya, Dr. D. R. Threlfall and Prof. T. W. Goodwin), 80
Uchida, Dr. I. A., *et al.* : Dizygotic Twins with XX/XY Chimerism, 191
Uggla, Dr. A. H. : *Obituary* by S. Savage, 328
Uhrick, J. R., *et al.* : Immunochromatographic Partition of Soluble Antigens on Columns of Insoluble Diazo-gamma-globulins, 265
Ullaland, S. L., and Trefall, Prof. H. : Long-period Pulsations of Auroral-zone X-rays, 1148
Ulrychová, M., *et al.* : Influence of Serum of Children and Adolescents on the Growth of Plants, 1010
Ultra-high Vacuum : A Simple Mass Spectrometer for the Analysis of Argon at (E. Farrar *et al.*), 531
Ultrastructure of Human Leucocytes synthesizing DNA (Dr. E. H. Cooper and Dr. D. R. Inman), 894
Ultrastructure of the Sensory Hair-cells in the Labyrinth of the Ammocœte Larva of the Lamprey, *Lampetra fluviatilis* (Prof. O. Lowenstein and M. R. Osborne), 197
Ultra-violet Radiation : A Sensitive Chemical Actinometer for (H. Morgoson and A. Gregoriades), 676
Underground Gasification of Coal, *review* by Prof. R. J. Sarjant, 969
Under-water Research, 1036
Underwood, Dr. G. : The Life of the Rainbow Lizard, *review*, 1021
Unicellular Green Algae : Effect of Gibberellic Acid on the Growth and Multiplication of Some Soil Micro-organisms and (S. Saono), 1328
Unio Mussels of Lake Maggiore, 1960-63 : Manganese-54 Concentration in Fall-out, Water and (P. Gaglione and Prof. O. Ravera), 1215
United Kingdom Postgraduate Awards, 1964-66, 925
United Nations : Department of Economic and Social Affairs. *The United Nations Development Decade : Proposals for Action*—Report of the Secretary-General, 108
United States : Academic Forecast for 1965-75, 229
Bureau of Standards (S. Weintroub), 1039
Coast and Geodetic Survey : Dr. J. S. Rinehart appointed director of research and development, 21
Department of Commerce : National Bureau of Standards : Annual Report 1963, 1039
Institute for Biomedical Research, 1142
National Academy of Sciences Advisory Group, 229
National Academy of Sciences and the National Research Council : *Organization and Members* 1963-64, 128
National Academy of Sciences and the Smithsonian Institution : Post-doctoral Research, 1037
National Science Foundation. NSF 64-14 : *Research and other Activities of Private Foundations*, 1960, 1259
Public Health Service : National Institutes of Health Statement, 209
Research Station in the Antarctic Peninsula, New (Prof. T. O. Jones), 825
United Steel Co. Ltd., booklet on Financial and Management Accounting, 730
Universities Council for Adult Education, 1962-63, 330
University Appointments Boards in Britain, 1145
University College, Dublin : Chair of Biochemistry, 1254
University Entrance Requirements for first Degree Courses in the United Kingdom : Compendium of, 526
University Finance in Britain, 733
University Foundation, Brussels, forty-third annual report, 428
University Grants Committee : *University Appointments Boards*, 1145
Returns from Universities and University Colleges in receipt of Exchequer Grant, Academic Year 1962-1963 (Cmnd. 2456.), 733
University of Aberdeen : Appointments, 431, 925
University of Belfast : Appointments, 431
Dunville chair of physiology, 524
University of Birmingham : Appointments, 630, 830
Chair of Crystallography, 1035
Chair of Genetics, 1138
Chair of Microbiology, 1255
University of Bristol : Appointments, 830
University of California Publications in Geological Sciences, 430
University of Delhi : Prof. P. Maheshwari, 22
University of Edinburgh : Appointments, 830
University of Keele : Appointments, 526
University of Leeds : Appointments, 526, 925
Chair of Agricultural Chemistry, 1138
Prof. I. D. Rattee's inaugural lecture, 1017
University of Liverpool : Chair of Applied Mathematics, 1138
University of London : Appointments, 526, 630, 925, 1140
Chair of Botany (Queen Elizabeth College), 21
Chair of Environmental Design, 626
Chair of Inorganic Chemistry (Queen Mary College), 729
Imperial College of Science and Technology, Substance of Sir William Holford's Lecture on Commemoration Day, 616, *Prospectus* 1965-66, 1258
University College *Calendar* 1964-65, 1258
University of Nottingham : Prof. F. S. Dainton appointed Vice-Chancellor, 732
University of Oxford : Expedition to Ascension Island, 1964, 722
University Gazette, 1141
University of Pennsylvania : Appointments, 630
University of Rhodesia and Nyasaland : Appointment, 1139
University of Sheffield : Appointments, 431
University of Southampton : Appointments 526, 830
Chair of Aeronautics and Astronautics, 1035
University of Strathclyde : Appointments, 127, 630
University of Sussex : Chair of Plant Physiology, 729
Prospectus 1964-65, 925
University of Warwick : Appointments, 127
'Unrewarded' Exploration and Learning of Complex Mazes by Wild and Domestic Mice (Prof. D. H. Brant and Prof. J. L. Kavanau), 267
Unsaturated Polyesters (H. V. Boenig), *review* by R. N. Lewis, 966
Upper Mesozoic of Kashmir, India : New Species of *Schizaea* Spore from the (N. G. Lukose), 566
Upper Pleistocene on the East African Mountains : Evidence for a Considerable Depression of the Vegetation Belts during the (Miss J. A. Coetzee), 564
Uptake of Labelled Precursors of Melatonin by the Epiphysis of *Xenopus laevis* (H. M. Charlton), 1093
Uptake of Potassium at Low Temperatures in Kidney Cortex Slices of Hibernating Mammals (Prof. J. S. Willis), 691
Uptake of Protein by Regenerating Liver Cells (Dr. T. Ghose and S. C. Tso), 1210
Uptake of Tetracycline by Human Bone *in vitro* (Dr. J. Deleu and Dr. H. Bohr), 1103
Upton, A. C., *et al.* : Factors affecting the Expansion of the Stem Cell Pool in Transplanted Mouse Bone Marrow, 351
Uranium Distribution in Drake Passage Waters (Dr. Y. Sugimura, T. Torii and S. Murata), 464
Urch, Dr. D. S., and Massey, Dr. A. G. : Nonaboronnonachloride, 877
Urea as a Fertilizer, 230
Ureter : Tumours of the Kidney and (edited by Sir Eric Riches), *review* by J. D. Fergusson, 1241
Urethane Hyperglycæmia and Hypothalamic Activation (Dr. H. Reinert), 889
Uridine Ribonucleotide Synthesis by 5-Halogenated-2′-deoxyuridine Analogues : Inhibition of (Prof. J. E. Stone), 190
Urinary Excretion of Amphetamine in Man : Rhythmic (Dr. A. H. Beckett and M. Rowland), 1203
Urinary Excretion of Beta-Amino-Isobutyric Acid and Taurine in Monoglism (Prof. H. O. Goodman, Dr. J. S. King, jun., and Dr. J. J. Thomas), 650
Urinary Resorcinol Sulphate : Origin of (Dr. G. Curzon and Dr. R. T. C. Pratt), 383
Urine of Women during the Elaboration of Œstrogen : Methylhistamine and Histamine in the (Prof. J. P. Green *et al.*), 1165

VAINIO, Dr. T., et *al.* : *In vitro* Cytotoxic Effect of Lymphoid Cells from Mice Immunized with Allogeneic Tissue, 453
Vaizey, J. : The Control of Education, *review* by N. Morris, 309
Valentine, Dr. R. C. : Sub-units of the Catalase Molecule seen by Electron Microscopy, 1262
Valette, Prof. G., and Ozan, K. : Action of Enzymatic Inhibitors (Potassium Cyanide and Sodium Fluoride) on Muscle Fibre Sensitivity to Potassium Ion, 586
Valeur Nutritionnelle des Protéines : Symposium organisé le 15 Novembre 1962 sous l'Egide de la Délégation Générale à la Recherche Scientifique et Technique (Annales de Biologie Animale, Biochimie, Biophysique, Vol. 3, Numéro Hors-série 1), *review* by M. Spencer, 5
Van Alten, Prof. P. J. : Duration of Embryonic Hypersensitivity and its Relation to the Level of Differentiation of the Chick, 797
Van de Hulst, Prof. H. C., awarded the Rumford Medal, 728, 1129
van der Borght, O., and van Puymbroeck, S. : Active Transport of Alkaline Earth Ions as Physiological Base of the Accumulation of some Radionuclides in Freshwater Molluscs, 533
Vanderhaeghe, H., *et al.* : Influence of Basic Antibiotics on Serum- and Liver-cholesterol Concentrations in Chicks, 1306
Van Die, Dr. J., *et al.* : Petiole Bleeding Sap in the Examination of the Circulation of Nitrogenous Substances in Plants, 1073
Van Dilla, Prof. M. A., et *al.* : Detection of an Interstellar Flux of Gamma-rays, 766
Van Dyke, Dr. R. A., et *al.* : Synthesis and Metabolism of Halothane-1-^{14}C, 471
Van Graan, C. H., and Wyndham, Prof. C. H. : Body Surface Area in Human Beings, 998
van Puymbroeck, S., and van der Borght, O. : Active Transport of Alkaline Earth Ions as Physiological Base of the Accumulation of some Radionuclides in Freshwater Molluscs, 533
Van Riel, Prof. J. : Transformation of *Leptospira*, 203
van Straaten, L. M. J. U. (edited by) : Deltaic and Shallow-Marine Deposits : Proceedings of the Sixth International Sedimentological Congress, 1963, *review* by Prof. C. F. Davidson, 418
van Venrooy, W. J. W., and Poort, Dr. C. : Detection of Enzymes in Agar Electropherograms, 684
Vanadium Complexes with Metal-to-metal Bonds : Seven Co-ordinate (A. S. Kasenally et *al.*), 871
Vanneste, W., and Allen, B. T. : Chlorine Hyperfine Splittings in Phenoxy Free Radicals, 991
Vapour : Absorption Spectra of Silver (Prof. C. Shin-Piaw and W. Loong-Seng), 276
Vapour Pressure of the Chemical Elements (A. N. Nesmeyanov), *review* by Prof. J. R. Partington, 511
Vapour Pressures of Xenon (77°-180°K) and Krypton (77°-130°K) (A. Grütter and J. C. Shorrock), 1084
Variant, A New, of Transferrin from Greece (R. F. Murray, jun., J. C. Robinson and Dr. B. S. Blumberg), 382
Variations in the Rate of Induction of Chemical Carcinogenesis according to Differing Psychological States in Rats (Dr. M. R. Anderson), 55
Varley, Prof. G. C. : The Life of Insects, *review*, 955
Vas, Dr. M. R., et *al.* : Effects of Erythromycin and Tetracycline in Human Bone-marrow Cultures, 1100
Vasa Deferentia, and the Genitalia of the Australian Earwig, *Labidura riparia truncata* (Dermaptera : Labiduridae) : Independent Development of the Male Gonads and (Dr. E. T. Giles), 1109
Vectorial Capacity : Prognosis for Interruption of Malaria Transmission through Assesment of the Mosquito's (C. Garrett-Jones), 1173
Vegetables : Phenolics in Normal and Diseased Fruits and (Dr. M. K. Seikel), 337
Vegetation Belts during the Upper Pleistocene on the East African Mountains : Evidence for a Considerable Depression of the (Miss J. A. Coetzee), 564
Veil Cells of Fruit Bodies of *Coprinus lagopus* sensu Buller : Recovery of Monokaryons from (J. W. Cowan), 1113
Vena Cava in the Rat : Drinking caused by Constriction of the Inferior (Dr. J. T. Fitzsimons), 479
Venables, Sir Peter : Technical Teaching and Instruction, *review*, 975
Venkata Ram, Dr. C. S. : Resistance of Tea Plants to Blister Blight in Soils augmented with Nickel, 1227
Vennart, J. : Use of Whole-body Counters in Radiological Protection, 1041
Venulet, J., and Schlutz, G. O. : New Molluscicide 1-(*p*-Nitrophenyl)-2-amidinurea Hydrochloride (T 72), 900
Vergroesen, A. J., et *al.* : Factors Influencing the Radio-protection of Tissue Culture Cells by Sulphydryl Compounds, 246
Verona, O. and Benedek, T. : Iconographia Mycologica, VIII, IX and X, *review* by R. W. G. Dennis, 316
Vertebrate Retina : Early Receptor Potential of the (Dr. R. A. Cone), 736 ; (Prof. K. T. Brown and M. Murakami), 736
Vertebrates : Social Behaviour and Organization among (edited by W. Etkin), *review* by Dr. W. H. Thorpe, 513
Viruses of (Sir Chrostopher Andrewes), *review* by Dr. F. K. Sanders, 216
Vertical Distribution of Radionuclides as Measured in Oceanic Animals (Prof. W. G. Pearcy and C. L. Osterberg), 440
Verticillium Conidia in Xylem Sap of the Hop (*Humulus lupulus* L.) : Occurrence and Dispersal of (Dr. G. W. F. Sewell and J. F. Wilson), 901
Vesalius, Andreas, of Brussels, 1514-1564 (Prof. C. D. O'Malley, *review*, 953
Vevers, Dr. H. G., and Millott, Prof. N. : Axial Organ and Fluid Circulation in Echinoids, 1216
Vicente, Dr. R. O., and Jeffreys, Sir Harold : Nearly Diurnal Nutation of the Earth, 120
Viktorov, S. V., et *al.* : Short Guide to Geo-Botanical Surveying, *review* by W. D. Clayton, 419
Villi in Postmature Human Placentæ : Compensatory Growth on (Z. P. Zhemkova and O. I. Topchieva), 703
Viola, M. : Marked Decrease of DNA in the Nuclei of the Adrenal Medulla of Rats exposed to Cold, 1094
'Viractin' : a Prophylactic Agent against Upper Respiratory Infections (Prof. B. E. Leach, P. E. Hackman and Dr. L. W. Byers), 788
Virological Technique (D. W. G. Busby, W. House and J. R. Macdonald), *review*, 1023
Virology : Selected Papers on (edited by N. Hahon), *review* by Prof. K. M. Smith, 959
Virus, An Unidentified, which causes the Rapid Production of Tumours in Mice (J. J. Harvey), 1104
Virus Diseases : The Background to Chemotherapy of (Prof. C. H. Stuart-Harris and Dr. L. Dickinson), *review* by Sir Christopher Andrewes, 959
Virus Specific Ribonucleic Acids in Baby Hamster Kidney Cells Infected with Foot-and-Mouth Disease Virus (Dr. F. Brown and B. Cartwright), 855
Viruses of the Columbia *SK* Group in Sciuridae in Britain : Antibodies to (Dr. A. D. Vizoso and R. Hay), 56
Viruses of Vertebrates (Sir Christopher Andrewes), *review* by Dr. F. K. Sanders, 216
Visceral Skeleton of *Acanthodes* : Reinterpretation of the (Dr. R. S. Miles), 457
Visser, Dr. S. A. : Molluscicidal Activity of Surface-active Agents on the Snail *Biomphalaria sudanica* ; a Vector of Bilharzia, 492
Oxidation-reduction Potentials and Capillary Activities of Humic Acids, 581
Visual System, Avian : Organization within the Central and Centrifugal Fibre Pathways in the (J. I. McGill), 395
"Vitamin B_6 in Metabolism" and "Some Aspects of the Biochemistry of Protein and Peptide Hormones", Colloquia on, 925
Vitamin B_{12} in Plasma in Chronic Myelogenous Leukæmia : Abnormal Transport of (Dr. C. A. Hall and A. E. Finkler), 1207
Vitamin *E*-deficient Rats : Effect of *d*-Gamma-tocopherol on the Incidence of Teratogeny in (Prof. D. W. King), 785
Vitamin K_2 (40) in *Chromatium vinosum* : Ubiquinone-40 and (L. K. Osnitskaya et *al.*), 80
Vitamins, Fat-soluble, and Biological Membranes (Dr. J. A. Lucy and J. T. Dingle), 156
Vitamins and Coenzymes (Dr. A. F. Wagner and Dr. K. Folkers), *review* by Dr. A. M. Copping, 614
Vizoso, Dr. A. D., and Hay, R. : Antibodies to Viruses of the Columbia *SK* Group in Sciuridae in Britain, 56
Vnenchak, J. M., and Muus, Prof. J. : Isozymes of Salivary Amylase, 283
Vogt, Dr. M. : Sources of Noradrenaline in the 'Immunosympathectomized' Rat, 1315
Volatile Liquids to Paper Chromatograms : Semi-automatic Transfer of (Dr. R. E. Bailey et *al.*), 485
Volcans et leur Activité, Les (A. Rittmann), second edition, *review* by Dr. V. A. Eyles, 719
Volkenstein, M. V. : Configurational Statistics of Polymeric Chains, *review* by Dr. W. R. Moore, 963
Volpert, W. A., *et al.* : Release of Adenine Nucleotide from Nerve Axons, 1000
Volume Change accompanying Passive Stretch of Frog Muscle (Prof. R. J. Baskin and P. Paolini), 694

CUTROCK ENGINEERING CO. LTD., 35 BALLARDS LANE, LONDON N.3

A NEW IMAGE FOR LIBRARY SERVICES

THE first research report to be published by the Research Institute for Consumer Affairs is not, as its title might suggest, about the London Library but about the use which is made by the Londoner of seven borough libraries—those of Chelsea, Finsbury, Hampstead, Lewisham, Stepney, Stoke Newington and Wandsworth—chosen to represent the metropolis as a whole*. It is thus essentially a complement to the Roberts Report on the Public Library Service, and to the subsequent report of the Working Party on Standards of Public Library Service, dealing with the subject from the point of view of the user (*Nature*, 200, 615; 1963). Its ultimate recommendations are based on the assumption that an efficient library service should concern itself with the kinds of people whose needs are to be met, the numbers who are being and who should be served, and the way in which the service is working in practice. Librarians are likely to reach more people more effectively if they are guided by knowledge about the people they are serving or failing to serve.

In a statement sent to the Ministry of Education, the Association of Special Libraries and Information Bureaux noted that the Roberts Committee and the Working Party all assumed in their reports that the purpose of the whole library system is to satisfy readers, and observed that little attempt seems to have been made to find out how far readers are, in fact, satisfied. Mr. B. Groombridge, in his report, bases his findings on the facts elicited from a sample of more than 1,300 adult Londoners, and the core of the report deals with a representative 500 of these. It recognizes that over the past forty years substantial progress has been made in the extent and the standards of public library service, and that even to raise standards throughout Britain to a level comparable with that achieved by the seven boroughs surveyed would, in many areas, represent substantial progress.

Nevertheless, while the popular prestige of public libraries is immense, the present demands made on them are relatively light, and the regard in which they are held should be taken as an asset, as goodwill with which to make more progress, rather than as a sign that enough has been achieved. Apart from the fact that illiteracy prevents many people from using what libraries have to offer, nearly half the adult population have never been enrolled as members of a public library and actual users probably number no more than one in three. Moreover, the libraries' potential public is limited by the stimulus or the damage that it has received from other sectors of social life, and it should also be remembered that to go regularly to a public library even to borrow light fiction is to exercise more initiative and to show more cultural resourcefulness than most people do.

Mr. Groombridge accordingly maintains that, while possibly making public libraries more efficient, too much concern with standards and too little with the people for whom the service is intended is not likely to make them more effective. Concern for the extent and nature of holdings, for example, must be balanced by some regard to issues per head because that is a criterion of the service relation between library and user. A public library in its truest sense should reflect the heterogeneity of the public to be served, and not only supply the needs of a few special sections of that public. It may well be expected to have regard to the needs of the student population, for example, but it must be able and ready to respond to the increasing demands which the decrease of illiteracy and the expansion of further education are certain to bring.

From the point of view of public awareness, Mr. Groombridge puts publicity first. A high standard of public service may be the best form of advertisement for any library, but the fact remains that many potential readers have no idea what the public library has to offer them, or even of its existence. A continuing and many-sided publicity campaign is plainly needed. Librarians cannot afford to neglect any device aimed at making choice more efficient, or at making their professional knowledge fully and easily available to the people who read. The, he thinks, may be the biggest single transformation needed to increase the effective contact of libraries with the public.

With this more creative and less bureaucratic relation between the library staff and the public, added to the existing goodwill, the question of stock is likely to be approached in the right way. No worse criticism could be made of a public library than that the books a reader wants are not available from it, but Mr. Groombridge found that nearly a quarter of those who had ceased to use a public library had done so for this reason, and a third of those using the borough libraries made this criticism to a lesser or greater degree. This, moreover, is the essential test of efficiency that should be applied to any branch library, but making allowances for the obvious limitations of such a unit. Again, on the question of reference, it is not simply a matter of holdings but of the attitude and availability of the library staff, and the establishment of the more creative relation already suggested could be a decisive factor.

While finance is important, it is not the sole or, possibly, even the most decisive factor, and Mr. Groombridge makes other suggestions which could help to bring libraries more effectively before the public. The conception that libraries are for readers is fundamental, but libraries should be wary of the assumption that readers must of necessity go to the library itself. Already some services are rendered to local voluntary groups, or to dependent groups such as the elderly and the housebound, but a more imaginative look at such extra-mural services, particularly in the context of expanding further education, is plainly desirable. Libraries cannot, indeed, meet these wider needs without more money for staff as well as for books, and on a scale which will enable them to attract and retain professional staff of the calibre needed. Whether, in the end, public libraries will be able to nourish adequately the literacy of a society in which standards of education are steadily rising will ultimately depend not on the imagination and ability of the professional librarian but on the standards and resources which the public are willing to provide.

It should not be overlooked that the survey on which Mr. Groombridge's report is based was supported by a

* *The Londoner and His Library.* By Brian Groombridge. Pp. viii + 124. (London: The Research Institute for Consumer Affairs, 1964.) 15*s*.

grant from the Library Association. The discussion at the annual conference of the Library Association at Birmingham on July 6 on "Library Services for Students" is closely related to the general theme of the report. This is especially true of the papers dealing with students' needs by Mr. A. Rhys Hughes, and with public libraries by Mr. E. A. Clough. It is also true to some extent of the other two papers—Mr. J. A. Dearden considered "Further Education College Libraries", and Mr. D. T. Ricknell discussed the memorandum of evidence submitted by the Library Association in February to the Committee on Libraries set up by the University Grants Committee and the Minister of Education.

Mr. Rhys Hughes, as president of the National Union of Students, was concerned with presenting the student's point of view. While challenging the view that all students could spend £30 each year on books, he suggested that some students might welcome more tutorial advice on buying books; he also stressed the importance of residential provision in relation to the use of libraries. His comments on guidance and on library hours were constructive and should be noted by the Committee on Libraries. He did not regard it as sound that the local public library should, during university vacation, be the student's main source of books. This is something that might well be examined as a particular aspect of library co-operation, both between university libraries and between these and the public libraries.

Mr. Clough was concerned with the magnitude of the potential demand on public libraries, not simply that coming from university or college students, but from the part-time students and private-study students whose numbers may well approach a million within the next twenty years. There is no doubt that both in London and the provinces, public library authorities must increase their services to students, particularly their reference services, quite apart from a possible doubling of the library services in the universities and colleges, and this expansion should be started now. Public library services are an important part of the educational fabric of Britain and this should be recognized at the national as well as at the local level. Moreover, as Mr. Clough observed, what is needed is an immediate increase, of the order of £1·5 million a year, for the provision of reference library services and other services to students.

Mr. Dearden was content to indicate how the libraries of the colleges of further education, including those of the teacher training colleges, fit into the general pattern, and how they are affected by the standards prevailing elsewhere, both in provision of books and services and in respect of salaries of staff. The problem has to be seen as a whole and the contribution which any particular section makes should not be considered in isolation. It is perhaps from this point of view that the memorandum submitted by the Library Association and discussed by Mr. Ricknell is of prime importance.

Much of this memorandum is concerned with the points made by Mr. Hughes, Mr. Clough and Mr. Groombridge, and it demonstrates convincingly the way in which the university libraries and the service they render are linked with the library services in Britain. It is recognized that the prime function of the library in an institution of higher education is to support the teaching and research of the institution itself and that the service customarily given to others should not be allowed to override this prime purpose. Nevertheless, the value of the technical advisory services offered to advanced research workers by industrial libraries and others is noted in the Library Association's memorandum. The memorandum suggests that, although a considerable specialist staff would be needed, such technical information services should receive very high priority in the colleges of advanced technology.

The memorandum consists of replies to some twenty-four questions put by the Committee on Libraries, six of which are specifically concerned with the provision of books for undergraduate students. Here, Mr. Ricknell points out that the old conviction that students should buy their own text-books and that the university or college library should not multiply copies of standard works is no longer tenable and flies in the face of common sense. The difficulty is that inadequate book funds may compel libraries to curtail the range of their research material if a large part of this fund has to be used for duplicate copies of standard material. The Library Association believes that students should be encouraged to buy a reasonable number of essential books for themselves, including the prescribed texts. Moreover, it directs attention to the value of improved reading lists provided by the teaching staff and of an officially recognized bookshop on the campus. The Association also suggests that the whole system of students' grants for books should be reinvestigated, but, apart from a reservation on the introduction of earmarked book tokens, Mr. Ricknell adds nothing beyond the suggestion of a controlled experiment in the use of a subscription library of text-books in at least one university.

The Library Association insists that undergraduates should be trained to use the main collection in the university library, whatever special provision is made for their needs. It puts all its experience and authority behind the centralization of book selection and acquisition within a university in the university library, and questions the relative value of departmental libraries and of those at the halls of residence. Not surprisingly the memorandum comments trenchantly on the provision of seating accommodation in university libraries and on hours of opening. It suggests that there should be accommodation for not less than 25 per cent of student places, and attributes the overcrowding of public libraries by students to shortcomings in the accommodation and accessibility of the university and college libraries.

There is also a reference to the vacation problem, on which the Committee on Libraries put a leading question, though here, again, there is still the problem of adequate reading space. Public libraries recognize that they have a part to play in meeting students' needs for both reference and lending, especially during vacation, but universities should also do all they can in this respect, if necessary by extending the opening hours of their reading rooms during vacation. Mr. Hughes suggested that reciprocal arrangements for vacation reading might be made between universities and other institutions of higher learning, and between the university attended by a student and that of his or her home town or area.

The extension of opening hours is linked with the provision of adequate staff, and Mr. Ricknell also points out that it is also linked with the provision of canteen facilities. Once again we are back to adequate finance and, in general, the memorandum from the Association fully supports the argument of the memorandum from the librarians of the new universities as to the need for much more generous provision for both books and periodicals. Even for a university of 3,000 undergraduates, 700 post-graduates and 350 academic staff it visualizes a basic library stock of at least 25,000 volumes, involving a capital

expenditure of some £500,000, and annual expenditure on acquisitions of at least £37,500.

Coming so soon after the memorandum from the librarians of the new universities, this independent, but authoritative, endorsement of the bulk of the argument of that memorandum is impressive. It demonstrates convincingly that what we should be looking for is not economy but an assurance that the provision being made for the academic libraries, whether in the new universities, the established institutions, or in the colleges of technology, is sufficiently generous, alike in respect of books, of periodicals, of accommodation and of staff and their terms of service. The range and scope of the questions put to the Library Association by the Committee on Libraries at least suggest that that Committee is now aware of the magnitude of the issues. The advice it has already received should go far to ensure that an imaginative report is forthcoming, with recommendations meeting the situation, provided that the Committee is sufficiently resolute to grasp the opportunities confronting it.

MAN'S DEVELOPING DILEMMA

Automation and the Future of Man

By S. Demczynski. Pp. 238. (London: George Allen and Unwin, Ltd., 1964.) 32*s*.

THE author of this book is obviously a well-read and highly intelligent man. His experience as a prisoner in a forced labour camp behind the Iron Curtain and his present occupation with automatic machinery and data processing equipment have caused him to ponder deeply on the problem of the moral nature of man. For, if it were true that future developments in cybernetics would reduce almost to nothing the distinction between the functioning of man and of machines and if, as seems likely by the end of the century, life were to be produced in a test-tube, does this not spell the beginning of the end of man's distinctive position in the world? Moreover, will not the increasing tendency, especially in the social sciences, to interpret human behaviour in deterministic terms destroy the basis for any moral code?

It is a pity that the author should have chosen such a cliché for a title and that he should have tried to cover so vast a field. The result is inevitably patchy. By far the best chapters are in the second part in which he considers the problems of free-will and determinism and of the relationship between mind and brain in the light of modern scientific knowledge.

Mr. Demczynski's solution to the dilemma posed by our increasing knowledge of the physiological processes of thought is the concept of increasing complexity of the system. In a similar way as matter is now known to be transmutable into energy, so matter when connected intimately with the mind tends towards the formation of extremely complex systems and so changes its own nature. Such complex systems exhibit freedom of choice and therefore make value discussions meaningful. If this concept is to be accepted it has to overcome two obstacles which the author faces, but, not surprisingly, does not resolve. The first is that it is in contradiction to the second law of thermodynamics by which entropy increases. His only answer to this is to suggest that there exists an opposing tendency in Nature corresponding to the Freudian concept of the will to live in contrast to the will to destroy and die. But this is a metaphysical concept which still leaves us seeking for a first cause for which the non-religous philosophers of the world have been searching through the centuries. The second obstacle is the problem posed by the increasing complexity of machines themselves. Here his solution is itself contradictory, for while he admits that machines may have the potential possibilities of men he believes that in some way this admission will enable the capacities of men to be clearly seen as superior. The comparison of man as he is with the best machines now available can only raise the status of the former.

These ideas are still a long way from the possibility of scientific investigation and they must remain a matter of belief and related as such to personal values. The author is a convinced humanist. To defy rationality, he writes, is to condemn in the end the whole effort of human civilization. Attracted to existentialism because of its support for the individual's freedom of will, he nevertheless realizes that a socially useful ethic cannot be built on the basis of complete subjectivity.

In the end his logical thinking joins his generous emotions in producing a dislike of a society the only motive of which is economic gain. This leads him to socialism and the need for planning.

Unfortunately, just when his industrial experience and analytical mind could have made a real contribution to the practical problems of society in an age of rapid technological change, the argument becomes discursive and leads to some rather unthought-out conclusions: for example, that government should be in the hands of an educated and socially conscious oligarchy—meaning the professional middle class.

Although he appears to believe that there is nothing to be hoped for between total disarmament and total destruction he dismisses the "few hundred thousand deaths due to increased leukæmia" caused by fall-out from nuclear tests, with very little argument, as necessary for the preservation of national independence and the Western way of living. All this is much beneath the level of the rest of this interesting attempt to face some of the philosophical problems raised by man's excessive ingenuity.

AUSTEN ALBU

SOCIAL CHANGE

On the Theory of Social Change: How Economic Growth Begins

By Prof. Everett E. Hagen. (Study from the Center for International Studies, Massachusetts Institute of Technology.) Pp. xvii+557. (London: Tavistock Publications (1959), Ltd., 1964.) 63*s*.

THE sub-title of this book is: "How Economic Growth Begins", and the author is concerned with a hypothesis about the changes that take place as a 'traditional' society moves towards modern entrepreneurial methods. What factors promote and what factors impede such a process?

So far as impediments are concerned, Prof. Hagen dismisses the familiar economic arguments—inability to save, lack of capital, lack of 'know-how', lack of markets and inadequate transportation. His arguments are compelling and he adduces evidence to show that economic growth has in fact taken place in the absence of these advantages. Of course the presence of adequate markets, adequate transport systems, capital and the rest of it are a help, but if they are provided from outside sources they will be useless unless the inhabitants for whose use they are intended have the right attitude of mind. His argument is similar to that of McClelland, who has put forward the view that material aid to underdeveloped countries is far less important than the inculcation of the 'achievement motive'.

Prof. Hagen's thesis involves a more complicated analysis. Underdeveloped countries have a 'traditional' culture, which is passed on from generation to generation by their child-rearing practices. This is treated in some detail; the upshot is that children are brought up in an 'authoritarian' atmosphere, in which they learn the rules

of their society from dominating adults, whose ways seem to them to be unpredictable. Indeed, the adults themselves feel surrounded by mysterious forces over which they have no control. All this makes the traditional way of life important as a safeguard against ever-present threats. In such a world, how can one dare to innovate?

The innovator, on the other hand, must be brought up by nurturing parents, so that he will have a sense of security and will find the world a predictable and orderly affair which he can manipulate with impunity—he has, after all, found in his own experience as a child that he can bring about minor changes in a predictable and desired direction by means of his own efforts.

It will be seen that Prof. Hagen draws heavily on the work of those social anthropologists who relate culture patterns to child-rearing methods, and this is a central part of his theory.

Now the traditional type of culture is stable; it has lasted so long in its various forms because it caters for the psychological needs of those who 'carry' it. How then can change come about? Here we come to the second part of Prof. Hagen's hypothesis. In a traditional society everyone has his place and a status, however lowly it may be, which is respected. Change comes when some section of the society has the respect withdrawn to which it feels entitled. The reaction to this withdrawal of respect is varied, but a broad pattern emerges. The members of the affronted group—the men, that is to say—feel angry, dejected and apathetic. The old culture has let them down, so they 'retreat'. The only way they can retain some status is by behaving more dictatorially in their homes, but this is a hollow gesture. Their children and their wives see through it. After a generation or so the women seem to play a part. Their nurturance becomes more important than the inculcation of obedience to a failure. They tend their children with care and affection, partly because they are disenchanted with their fathers and husbands. Thus the stage of childhood security is set and creativity becomes possible.

Such is the theory, and now several case studies are examined in the light of it. The course of English history is outlined and attention is directed to the fact that in the fifteenth century the upper classes started to withdraw respect from the common people, and evidence is produced to show that many of the early innovators sprang from just that stock. Next Japan, where the Tokugawa Shogunate demoted several sections of Japanese society, and there is some evidence that it was from those circles that entrepreneurs derived. In Colombia it was the inhabitants of an unpromising area that have made the greatest strides, and they were despised, because they worked with their hands, by people who lived in other and more fertile districts. Clifford Geertz compares two Indonesian towns, and produces supporting evidence.

In the case of colonies the withdrawal of status respect may be said to be universal throughout the whole of the conquered community. The blow was shattering and the ensuing apathy traumatic. In some cases some of the indigenous population came to 'identify themselves with the aggressor' and ape his Western ways, but this was all on the surface, and they did not acquire—and did not want to acquire—the driving force which is needed for administrative competence. Burma is taken as a case in point, and the case of Burma is followed by an analysis of the Sioux on two reservations in America.

How far has the case been made out? The second part of the hypothesis is not rejected. It seems plausible and well worth pursuing. But this is only part, and in a sense a minor part, of the theory. To detect the social origins of the innovators is essential, of course, but according to the main theory evidence is required for a change in child-rearing practices, and this, alas, is not forthcoming. The only cases of which we have some information—Japan and Bali, where one of the Indonesian towns is situated—present difficulties. The Japanese boy, as described by Ruth Benedict, has a permissive childhood, but when he goes to school he finds that he has to preserve the 'face' of his family in a highly structured society; and the insecurity of the Balinese child, as described by Mead and Bateson, seems scarcely conducive to creativity, if Prof. Hagen's hypothesis is correct. Perhaps, of course, there have been changes since these investigations were made, but it is surprising, since he lays such store by child-rearing practices, that Prof. Hagen has not dealt with them in some detail.

This does not, of course, mean that he is wrong, and he confesses that we do not know enough about these matters. However, if a change in child-rearing practices is so important, and if such changes are, as they must be, quite apparent, it ought not to be difficult to get evidence from the underdeveloped countries that are now achieving independence. Prof. Hagen believes that several—as many as four—generations may have to pass before such changes bear fruit, but clearly the next step is to make careful investigations into changing methods of dealing with children, and the new nations, after all, provide laboratory conditions.

W. J. H. Sprott

AN ANALYSIS OF EMPATHY

On the Problem of Empathy

By Edith Stein. Translated by Waltraut Stein. Pp. xxi+113. (The Hague: Martinus Nijhoff, 1964.) 14.50 guilders.

IT is wholly impossible to give an adequate account of this book without some preliminary reference, of a biographical nature, to the remarkable woman who wrote it.

Edith Stein was a Jewess, born in Breslau in 1891. She became assistant to Edmund Husserl in 1916 when he was at Freiburg-im-Breisgau. The present work is a translation of her doctoral thesis, with the omission of the historical introduction. In 1922 she embraced the Roman Catholic faith, and ten years later became a Carmelite nun. She took refuge at Echt (Holland) during the Nazi persecutions, and perished at Auschwitz in 1942. Such in brief was the dramatic life of devotion of the authoress. Without some knowledge of this background a reading of these pages, difficult as they are, would be almost meaningless.

One might think that a definition or at least a description of empathy would occur early in the discussion, but this is not the case: probably in the academic tradition of the period it was needless for the scholars of phenomenology with whom Edith Stein was so closely associated. Philologically, empathy is an attempt to translate the German *einfühlung*, or 'feeling-in', roughly paralleled by sympathy or 'feeling-with', and it is just at this point that a basic divergence from normal psychological methodology occurs. We are asked to consider a fundamental distinction between the living body (*Leib*) and the material body (*Körper*). The former takes its place, so to say, as the origin of co-ordinates of the spiritual world, whereas the latter is apprehended as a physical entity.

It is manifest that deep thinking along these lines will throw up innumerable problems in natural philosophy as well as in the cultural sciences (*Geisteswissenschaften*), more particularly aesthetics. In fact, an earlier investigator, Theodor Lipps (1851–1914), had noted a tendency for a human subject to 'copy' the outstretched arms of a statue in an attempt to emphathize *in* (not *with*) the essence of the object revered. Further, the connexion with axiology is close, since value-judgments may enter at once when the empathic bond is firmly established.

In the light of these general considerations, the pattern of the dissertation may become a shade clearer. First

appears the essence of acts of empathy, then the constitution of the psycho-physical individual, and lastly, empathy as the comprehension of mental persons. To students of Husserl it will seem remarkable how well Edith Stein has mirrored the master's aversion from psychologism, namely the insidious intrusion of purely subjective tenets into domains essentially logical. This volume is not very likely to appeal to experimental scientists, but it has significance for them if they explore the field of 'personal knowledge' as Polanyi has conceived it.

On the level of human experience, there can be little doubt that the attainment of a high degree of empathy is something which can be recognized as akin to a species of genius. An obvious example is the fusion of the whole personality of a great actor with that of his hero, or even with situations encountered by him. Less potent, but equally intriguing, are the cases in which master and pupil have shared a common intellectual quest, reaching perhaps a common goal. In these instances agreement is not necessary at all stages of the journey; what is important is that the thread of 'in-feeling' should never be strained beyond the elastic limit. It appears that empathic potential can build up substantially, and maybe lead to a break-through in discovery, or to the birth of new ideas.

Even in the workaday world, history produces vestiges of empathic reactions when, for example, an artist has exceptional respect for and understanding of his materials and so is likely to bring about a result of greater sensibility than one lacking, or largely lacking, in this quality. The phrase 'mastery over materials' is often heard and is misleading if it connotes coercion into inappropriate uses. Indeed, one of the outstanding features of a great work of art is the perfect fitness of the substances involved in reaching the final cause (in the Aristotelian sense) which the artist had in mind.

In brief, the background of this investigation is strictly phenomenological, which, however, does not destroy—in fact it enhances—its value to the philosophical psychologist. It is impossible to waive (in the manner of Husserl's 'reduction') sensations. They are just as surely given as judging, willing and perceiving.

A word of appreciation is due to the translator, who is a grand-neice of Edith Stein. She has reproduced the spirit of the thesis well, although there are one or two lapses from idiomatic English. An excellent point is the marginal pagination of the original text. Edith Stein served with the Red Cross in World War I and experienced empathy in the field; she was to live to write her great *Kreuzeswissenschaft* later on, and to seal it with her death.

F. I. G. Rawlins

NUTRITIONAL VALUE OF PROTEINS

Valeur Nutritionnelle des Protéines

Symposium organisé le 15 Novembre 1962 sous l'Egide de la Délégation Générale à la Recherche Scientifique et Technique. (*Annales de Biologie Animale, Biochimie, Biophysique*, Vol. 3, Numéro Hors-série 1.) Pp. 133. (Paris: Institut National de la Recherche Agronomique, 1963.) 11.50 francs.

THIS small volume contains the papers read at a symposium held under the auspices of the Délégation Générale à la Recherche Scientifique et Technique in Paris during November 1962. It contains some twenty papers organized in seven sections, and reflects work carried out on nutritional aspects of proteins in a number of research laboratories throughout France during 1961 and 1962.

In the first section there is a report of work carried out at the Metabolism Laboratory of the Institut National de la Recherche Agronomique on the amino-acid composition of proteins in animal and human foods, using the chromatographic technique of Moore and Stein.

Some new techniques are reported in the section on the digestion of proteins and the intestinal absorption of amino-acids. Because of the importance of the correct balance of amino-acids arriving simultaneously at the point of protein synthesis, the rate of digestion of protein was investigated, the distribution in the alimentary tract of the pig being determined at intervals; followed by an interesting account of work on the changes in amino-acid concentration in the portal vein during digestion. The use of different methods of estimation of protein quality was considered. For example, the microbiological method of Ford, using *Streptococcus zymogenes*, was found to give satisfactory correlation only for animal foods, not for soya oil-cake.

The effect of heat-processing of herring meal used for animal feeding was next considered at the symposium. The fish-meal heated at 60°, 90° and 130° C was examined in different laboratories by various methods: there was not, however, agreement on the degree of protein damage at different temperatures. One laboratory reported on the remarkable ability of a small supplement of fish protein in quadrupling the rate of growth of rats being fed with gluten as the source of protein in the feed.

The significance of the ratio of calories to protein was emphasized in the next section, in which the work of various laboratories led to the view that the biological value of the proteins is an important factor, affecting the spontaneous caloric intake of both rats and chicks in growth experiments. The protein value of various African foods was considered, in relation to the fight against kwashiorkor in West Africa. These foods included three types of African beans, and the traditional methods of preserving fish were also reviewed.

This useful symposium concluded with three papers concerned with biochemical aspects of proteins: the relationship between the significance of gliadin in cœliac disease; the isolation of α-lactalbumin from cows' milk; and investigations of glyco-proteins in human and cows' milk.

The organizers are to be congratulated on this valuable contribution to our understanding of the subject—the book will be of great interest to all workers in the field.

M. Spencer

NEUTRON DIFFRACTION

The International Encyclopedia of Physical Chemistry and Chemical Physics

Topic 11: The Ideal Crystalline State, Vol. 1: Applications of Neutron Diffraction in Chemistry. Edited by M. Blackman. Pp. xi + 141. (Oxford, London, New York and Paris: Pergamon Press, 1963.) 42*s*.

THE de Broglie wave-length of a thermal neutron, that is, a neutron the kinetic energy of which corresponds to room temperature, is of the order of a few Ångströms, which is about the same as the distance between atoms in a solid or liquid. Thus neutrons may be used, just like X-rays, to provide information about the structure of solids and liquids. As they have no charge neutrons cannot be accelerated or focused; hence it is necessary to start with a powerful source for diffraction experiments. Such sources have become available in the past two decades with the advent of the nuclear reactor.

Unlike X-rays, which are scattered by the electrons in the atom and which are, therefore, only scattered weakly by atoms of small atomic number, neutrons are scattered mainly by the nucleus itself. The scattering from different nuclei varies in an irregular manner throughout the Periodic Table. It is this difference which makes neutrons such a useful complement to X-rays. In particular, the

scattering of neutrons by hydrogen is quite appreciable; so neutrons may be used to locate the hydrogen atoms in substances where these are present alongside heavy atoms. A second application of neutron diffraction is the investigation of chemical ordering in compounds or alloys which contain elements that are near neighbours in the Periodic Table. Such elements have similar scattering properties for X-rays but are often quite different for neutrons.

Applications of Neutron Diffraction in Chemistry by Prof. G. E. Bacon is devoted in the main to a description of these two classes of experiments.

The first chapter gives the principles and general experimental methods of neutron diffraction. Then follow chapters on the investigation of hydrogen in various inorganic and organic compounds, and also of carbon, nitrogen and oxygen in certain heavy element compounds. Experiments on alloys of transition metals and on spinel structures, which have been extensively studied by neutron methods, are further described.

The neutron has a magnetic moment and so, in addition to being scattered by the nucleus, it is scattered by the electrons in those atoms that have a resultant magnetic moment. This property means that neutrons can be used to study the ordering of the spins that occurs in ferro-, antiferro- and ferri-magnetic materials. Although not primarily of chemical interest, a chapter on such investigations is included. This particular field has proved a triumph for neutron methods. We now know that, in addition to the relatively simple magnetic structures mentioned here, other more complicated structures, such as spiral structures ($Mn\ Au_2$) and what might be called an alternating umbrella structure (Cr Se), occur in Nature.

The book is written by one who has done much work in the field. The text is straightforward, the diagrams are clear and helpful and there are copious references to the original work. The book is well produced.

G. L. Squires

GENETICS OF BACTERIA AND BACTERIOPHAGE

The Genetics of Bacteria and their Viruses

Studies in Basic Genetics and Molecular Biology. By Dr. William Hayes. Pp. xii+740+25 plates. (Oxford: Blackwell Scientific Publications, 1964.) 84*s*. net.

ONLY some twenty years have passed since the discoveries which ushered in the era of intensive investigation of the genetics of micro-organisms—the demonstration by Avery and his colleagues that the active principle in the type-transformation of the *Pneumococcus* was deoxyribonucleic acid; Luria and Delbrück's fluctuation test, and, a little later, Tatum and Lederberg's discovery of sexuality in bacteria.

Yet bacteria and their viruses are now perhaps the most fruitful experimental material for fundamental investigation in genetics, and Dr. Hayes has needed more than 600 well-filled pages to provide what he rightly describes as a moderately advanced text-book of the genetics of bacteria and bacteriophage. In his preface, Dr. Hayes states that in teaching microbial genetics to graduates in a variety of subjects, including the physical sciences, he found the main barrier to their perception was their ignorance of classical genetics and of genetical terminology. For this reason, among others, he provides in the first section of *The Genetics of Bacteria and their Viruses* a brief account of the observations and ideas of classical genetics, including Mendel's laws, and of the theory of genetical analysis.

He next proceeds to the examination of recombination and mapping, especially as applied to bacteria and phages; and to a short account of the specialized genetical systems of fungi. Part 3 deals with biochemical genetics, with some examples drawn from higher organisms illustrating the generality of the phenomena under consideration. Part 4 is devoted to the analysis of genetical fine structure, considered theoretically and taking as examples the transductional analysis of the loci concerned in synthesis of tryptophan and of histidine in *Salmonella* and Benzer's analysis of the r_{II} locus of phage *T*4. Part 5 concerns bacterial mutation and the expression of mutations. Part 6, of some 140 pages, is devoted to the physico-chemical mechanisms of heredity, including the structure and function of DNA and RNA, and the evidence of how they function to embody, and express, genetic information—in fact the genetic aspects of 'molecular biology'.

In his preface, the author says that his limited knowledge and experience of the methods of chemistry and physics have necessitated an approach which may appear naïve to the expert; be this as it may, I, as a non-expert, found the account here, as elsewhere, admirably clear and comprehensible. The second half of the book deals systematically with various genetic systems; bacteriophage, including physiology and the phenomenon of lysogeny; the structure of the 'chromosome', in phage and bacteria; recombination systems (transformation, transduction, conjugation) occurring in bacteria; genetic aspects of control mechanisms; and sex factors and other episomes.

The style throughout is pleasant and easy to follow; in those sections in which I felt competent to judge, the material was well chosen, all the more important facts, including those only very recently published, being included, so far as space permitted. The book is illustrated with numerous text figures, in many of which the use of red ink clarifies the representation of, for example, crossing-over; and also by 25 well-chosen and well-reproduced photographs. In the bibliography, of some 900 items, the citations include the titles of the papers and the text page numbers where they are cited; features which should greatly enhance the value of the book.

Dr. Hayes has performed a most valuable service in selecting and collating the essentials from the vast number of publications on this subject; and his book can be cordially recommended.

ANIMAL NOISES IN THE SEA

Marine Bio-acoustics

Proceedings of a Symposium held at the Lerner Marine Laboratory, Bimini, Bahamas, April 11–13, 1963. Edited by William N. Tavolga. Pp. xii+413. (London and New York: Pergamon Press, 1964.) 100*s*.

IN spite of the rapid development of air transport, the Atlantic Community still depends very largely on sea transport to carry its food, oil and raw materials. This fact is not lost on our potential enemies, who have built large submarine fleets. This in turn has stimulated the Western countries to put a great deal of effort into developing anti-submarine systems. Unfortunately the sea is a very difficult medium to work in, particularly with regard to the detection of underwater objects at long range. Electromagnetic waves (including light) are rapidly attenuated, and the only wave motion which travels reasonably well is sound, and then only at comparatively low frequencies. The problem is further complicated by the presence of reflecting boundaries at the surface and sea-bed, and by refraction of the sound by gradients of temperature and salinity, mostly in the vertical plane.

Marine animals are important to this problem in two ways. First, they make sounds which interfere with our systems. Secondly, they encounter similar problems themselves, and many of the more advanced vertebrates have evolved highly sophisticated detection systems

which may contain clues which would help us. After all, as one of the contributors to *Marine Bio-acoustics* points out, man's ear is probably atrophied compared with that of animals, but even we can estimate by ear the size of a room in which we are speaking, and we are remarkably good at picking out the sounds we wish to hear from a noisy background.

The subject is also, of course, extremely interesting from an academic point of view, and has important civilian applications. For example, some recent South African work on the hearing of sharks is part of a long-term programme to develop shark-repellent systems. However, most of the money is undoubtedly made available, particularly in the United States, because of the potential military importance.

The subject is at present in an exciting state. The considerable amount of work which has been done so far has raised a number of interesting questions, without, in many cases, providing more than a hint at the answers. For example, some of the sounds picked up are almost certainly used for echo-location purposes, but are of a complex form the purpose of which we do not fully understand.

A symposium on "Marine Bio-Acoustics" was held at the Lerner Marine Laboratory, Bimini, Bahamas, during April 11–13, 1963. *Marine Bio-acoustics* incorporates 23 of the papers presented at the symposium, together with the discussion. The papers are collected into five categories. The first deals with a large underwater acoustic-video system installed at the Lerner Marine Laboratory, the second category deals with physical and acoustic aspects, the third with biological sound producers in the sea, the fourth with marine fishes as acoustic detectors, and the fifth with the special acoustic problems of cetacean research. The book forms a very useful survey of the present state of this subject.

All the contributors to this symposium were from American organizations. Although the United States has almost a monopoly in this field, some useful work is being done in other countries. M. J. TUCKER

JORDAN'S FISH GENERA

The Genera of Fishes and a Classification of Fishes

By David Starr Jordan. Pp. xvi+800. (Stanford, California: Stanford University Press; London: Oxford University Press, 1963.) 140*s*. net.

D. S. JORDAN'S four classic papers entitled "The Genera of Fishes" and their taxonomic index "A Classification of Fishes" have been out of print and difficult to obtain for more than thirty years. Their reappearance as a single, moderately priced volume will receive a wide welcome.

Jordan practised as a taxonomist during a period when there was no international agreement on nomenclatural procedure. His monumental work on the fishes of north and middle America brought him face to face with innumerable problems of nomenclature and it seems likely that this experience more than any other was responsible for the "Genera". In effect, these papers were an attempt to bring some stability into zoological nomenclature. Further, as Prof. Myers emphasizes in his admirable introduction to the reprint, the "Genera" had the immediate purpose of bringing the acceptance and application of fish generic names into accordance with the Paris 'Rules' (1905) by selecting a nomenclatural type species for every genus. In this respect the "Genera" was perhaps a little premature. It was published before methods of applying the 'Rules' were widely understood and before zoologists had benefited from the International Commissions' *Opinions* published in 1920. Thus, the terms Jordan used to indicate the different methods by which a type species name was designated or recognized were not so exact or mutually exclusive as the future workers required. Consequently, these categories have never been adopted and have gradually fallen into disuse.

Be that as it may, Jordan's "Genera" is still an essential first reference to be consulted in any nomenclatural tangle; present-day fish taxonomists should gratefully recognize its importance in the history of their subject. Few works in zoology can have contributed so much to the stability of nomenclature or done so much of the essential spadework for succeeding workers.

Each of the four parts of the "Genera" deals chronologically and by alphabetically arranged authorship with the generic names proposed during the period it covers. For each genus a full bibliographical reference is given, and a type species selected according to the scheme defined in the second part. The total period covered is from 1758 to 1920. In the first part Jordan was assisted by his colleague, E. B. Evermann, who, it is thought, was largely responsible for the format and layout; later parts were the sole responsibility of Jordan. Inevitably in a work of this scope there are mistakes and omissions, but one cannot help but be impressed by their infrequency.

"A Classification of Fishes" was first published three years after the fourth part of the "Genera" (which covered the period 1881–1920). It had a dual purpose: to list in their families all generic names of fishes, living and fossil, published since the inception of binominal nomenclature and, secondly, to produce a new arrangement of fishes in their natural groups.

As a classification it was not entirely satisfactory, particularly since it contained few definitions of the groups involved and little discussion of their interrelationships. It was, in fact, largely a re-interpretation of Regan's classification. Unfortunately, Jordan did not justify the emendments he made and the modern student must remain ignorant of, and intrigued by, Jordan's reasons for disagreeing with Regan in those places where the two systems diverge. As a taxonomic bibliography the "Classification" remains unique and, despite the limitations imposed on it by the growth of ichthyological literature, an invaluable reference work. It is particularly valuable for the newcomer wishing to 'place' some genus he has encountered for the first time. The principal limitation to its use in this way was the lack of a single alphabetical index covering both the "Genera" and the "Classification". The four separate parts of the "Genera" each had an index, as did the "Classification". In the reprint edition, however, the several indexes have been omitted, to be replaced by a single comprehensive index based on a manuscript compiled by L. P. Schultz and the late H. M. Smith. The new index, now available for the first time, is a great help, for it serves also to correct misspellings in the text, to place genera omitted by Jordan from the "Classification" although included in the "Genera", and, finally, to put in their correct families some genera misplaced in the original publications.

Prof. Myers has greatly enhanced the value of the reprint by his informative introduction which not only reviews the historical importance of Jordan's five great works but also sets them in their present perspective and thus instructs in their correct use. Prof. Myers regrets that it has not been possible to revise, correct and bring up to date the work so as to cover the forty years of research since its publication. His remarks on this subject illustrate both the vigorous growth of ichthyology and particularly the awful stature of David Starr Jordan: "However, no one has been found with both the ability and the time to carry through such an extensive revision". It is with humility that modern zoologists should remember that the "Genera" and the "Classification" were but five works from a bibliography of more than 1,900 titles of which 645 were papers devoted to fishes; the others covered such diverse subjects as education, international affairs, philosophy, poetry and even children's books.

P. H. GREENWOOD

Analytical Chemistry

Edited by Carl E. Crouthamel. Vol. 3, Part 4: Pp. 95–162. 20*s*. net. Vol. 3, Parts 5–7: Pp. vii + 163–265. 30*s*. net. (Progress in Nuclear Energy, Series 9.) (London and New York: Pergamon Press, 1963.)

PART 4 of the third volume of *Analytical Chemistry* has the title "Critical Review of the Analytical Methods of the Titanium, Vanadium and Chromium Transition Element Groups" and is by R. Z. Bachman and C. V. Banks of the Institute for Atomic Research and Iowa State University. The authors point out that their contribution is limited to a consideration of "the so-called 'wet' methods of chemical analysis . . . reported (from) 1950 into 1961. Spectrochemical, X-ray fluorescence and radiochemical methods are deleted intentionally . . .". This severely restricts the utility of the article and perhaps denies its claim in the title to be a critical review of the analytical methods. In fact, while it is very useful to have a compilation of methods for separation and determination of these elements and a list of 574 references, the review is not really critical even in the aspects it covers, in that it lists the articles but does not, in general, guide the user.

Part 5, "Chemical Monitoring of Heavy Water Moderated Research Reactors", is by L. E. Smythe; while Part 6, "Recent Advances in the Analytical Chemistry of Beryllium", is by L. E. Smythe and T. M. Florence. The authors, from the Lucas Heights establishment of the Australian Atomic Energy Commission, write from several years' experience of both problems, and the result is comprehensive and authoritative. The beryllium article is much more critical than that on titanium, etc., which forms Part 4, and is consequently of more value to the reader, and, even though no claim is made for complete coverage, articles published in 1963 are mentioned, thus giving a much more up-to-date picture than that of Part 4.

Part 7, "A Large-Scale Facility for Chemical Research with Intensely Radioactive Materials", is by D. C. Stewart of the Chemistry Division of the Argonne National Laboratory. This is a useful description of that Division's new "hot laboratories" for chemical research or analytical service in direct support of research programmes. Not many readers will be called on to design such laboratories, costing more than four million dollars, but all who have to handle sizable amounts of radioactivity will find much of interest and value in this article. Perhaps we can look forward to another paper in a few years' time reviewing the operation of these facilities, with any second thoughts?

A. A. Smales

L'Électronique dans les Appareils de Contrôle Nucléaire

Tome 1. Par Georges Nicolo. Pp. 521. (Paris: Éditions Eyrolles, 1963.) 110 F.

THIS work is devoted to a discussion of electronic circuits used in nuclear reactor control installations. The author includes in this first volume extensive chapters on nuclear particle detectors (64 pp.); general circuit theory (113 pp.); compensation of valve heater voltage variations (38 pp.); stabilized voltage and current circuits (64 pp.); linear d.c. amplifiers (84 pp.); and logarithmic d.c. amplifiers (64 pp.); with, in addition, brief chapters on the elements of nuclear physics, the effects of radiation on materials, and applications of transistors. There is little indication of what is to be included in the second volume.

This is an elementary and uninspired book, with little of interest to the specialist. As an introduction to the subject, there is much to disagree with in the balance of the contents. Ionization chambers and counters, which are highly important in the context of reactor control, are given only a passing glance, whereas the relatively unimportant scintillation counter is treated at length. A fuller discussion of modern semi-conductor circuit techniques could have been hoped for, at the expense of some cuts in the space allotted to obsolescent electronic valve circuits and to the interminable, dull chapters on balanced heaters and stabilized supplies.

The most vehement protest must be made, however, at the quite deplorable number of mistakes both in the text and in the diagrams, mismatching of text and diagrams, misprints in the formulæ, sudden unexplained changes in symbolism, errors in simple algebra, and obscure algebraic derivations which seem almost calculated to confuse and infuriate the reader.

J. F. Hogg

Mushrooms and Other Common Fungi of the San Francisco Bay Region

By Robert T. and Dorothy B. Orr. (California Natural History Guides: 8.) Pp. 71 + 8 plates. (Berkeley and Los Angeles: University of California Press; London: Cambridge University Press, 1962.) 12*s*.; 1.50 dollars.

THIS small booklet, intended for the amateur, consists of a general introduction to the study of the larger, fleshy fungi, with brief descriptions of certain genera and notes on a few of the more common representative species occurring in the area. There is also a very much simplified key to a limited number of agaric genera.

The work is illustrated with line drawings which are remarkably effective and with very poor, and in some instances decidedly misleading, coloured photographs of fungi in their natural habitats. It is a pity that all authors and publishers have not as yet realized that when coloured photographs are used to illustrate works concerned with the identification of fungi they must not only be of a very high quality but must also be selected with a view to showing the diagnostic characters of the species. One cannot help feeling that many of the subjects depicted would have been better portrayed by a good black-and-white photograph. Particularly misleading are the illustrations of *Cantharellus cibarius* and *Helvella crispa*. In fact it seems very doubtful if the fungus shown under the latter name is correctly identified since it should be creamy-white, not brown! Similarly the illustrations of *Hygrophorus psittacinus* and *Lactarius deliciosus* would scarcely pass for the European species. The photograph of *Armillaria mellea* is so poor that it is unlikely that an amateur would be able to recognize it, and likewise that of *Tricholoma personatum*, where the characteristic lilac colour of the stem is completely lacking. Other photographs are so badly reproduced that the diagnostic features are completely obscured, as, for example, the gills of the *Russula* and the teeth of *Hericium coralloides*.

While this booklet contains much useful information and may stimulate its readers to go out into the field and look at mushrooms, they will, I am afraid, be liable to become thoroughly frustrated when they try to name their collections, on account of the relatively few species covered and the poor quality of the coloured plates.

D. A. Reid

Antibiotic-producing Microscopic Fungi

By V. I. Bilai. Pp. vii + 215. (Amsterdam, London and New York: Elsevier Publishing Company, 1963.) 60*s*.

THIS book is an English translation of МИКРОСКОПИЧЕСКИЕ ГРИБЫ-ПРОАУЦЕНТЫ АНТИБИОТИКОВ by V. I. Bilai, published at Kiev in 1961, unchanged apart from a modernization of the bacterial nomenclature in Table 17. After a brief account of the occurrence of microscopic fungi in Nature, and an assessment of the biological significance of the antibiotics they produce, the text deals successively with genera of fungi involved and the chemistry of their products. The longest chapter is, naturally, devoted to *Penicillium*, with taxonomy and illustrations based on those in the well-known monograph of Raper and Thom. There follow shorter chapters on *Aspergillus*, *Cephalosporium*, *Trichoderma*, *Trichothecium*, *Alternaria*, *Fusarium* and a few miscellaneous fungi. A brief final chapter discusses antibiotic properties of the toxins of fungi which cause mycotoxicoses in man and his animals.

R. W. G. Dennis

THE PERSONALITY OF BOTANY: THE RECIPROCAL RESPONSIBILITY OF BOTANY AND THE COMMUNITY*

By Prof. H. GODWIN, F.R.S.
University of Cambridge

My own acquaintance with the International Botanical Congresses began with the Cambridge Congress of 1930 at which Prof. Sir Albert Seward was president, and we had the support of the great Cambridge botanists, Sir Arthur Tansley, Dr. F. F. Blackman and Prof. F. T. Brooks, then general secretary of the Congress. It heightens my sense of pride and of obligation to be succeeding such distinguished teachers, and I am sorry that they, like many other friends of past congresses, Prof. Skottsberg, president of the Stockholm Congress, among them, are now lost to us. It is, however, of the essence of science that their contributions, made with a lifetime of exacting observation and thought, constitute a permanent part of the edifice of knowledge and have placed the world lastingly in debt to them. The thought of these losses reinforces the pleasure with which we welcome at this Congress such internationally honoured botanists as Prof. Bohumil Němec of the Charles University of Prague, now past his ninetieth year but still enviably active.

The growing complexity and extent of botanical science and the vast increase in attendance at congresses have forced some changes on our organization. The Montreal Congress recommended a reduction in the number of constituent sections, and this suggestion accorded with a widely expressed belief that scientific congresses in future should not attempt to cover at one time the whole field of knowledge that they represent, but should rather concentrate on those areas of greatest activity and importance and discuss where notable advances are being made. This policy, warmly endorsed by the International Union of Biological Sciences and followed with great success by the International Congresses of Genetics and Biochemistry, is that which we have adopted.

We have concentrated, therefore, on organizing symposia on all the most active and rapidly developing fields of botanical science. If the old structure of sections has been submerged, this implies no intention to suppress or play down any section of the botanical field of interest, but rather a determination to link all the fields together to their common advantage. The organization in symposia has involved the need to ensure for each meeting a nucleus of opening speakers, but a large and substantial amount of time should always be left for general discussion from the floor: if this is not done the major aims of the Congress are frustrated. The symposial organization has necessarily involved some restriction on the number of persons able to read formal papers at the Congress: to meet such cases there has been a generous provision for annotated exhibits with preprinted synopses: over 3,000 ft. of bench space has been allocated for this purpose. At every section also there has been provided facility for the meeting and discussion together of interested groups of specialists. We cannot afford a form of Congress organization which ignores the present pace of scientific advance.

Botanists were among the first scientists to organize international congresses, and it is now exactly one hundred years since the meeting in Brussels of the first International Horticultural and Botanical Congress under the direction of Eduoard Morren, rector of the Botanical Institute of the University of Liège: the overwhelming support for the tenth International Congress of Botany indicates the maintained vitality and continued growth of the subject through the century.

This large attendance, from sixty-nine countries, testifies not only to the vigour of botanical science, but also to appreciation of the many and evident advantages of the historic city of Edinburgh. Scotland and its fair capital have, moreover, both played a very important part in the development of botanical science. Already in 1670 Dr. Andrew Balfour and Dr. Robert Sibbald had rented a portion of the Royal Gardens at Holyrood House for the making of a Physic Garden, and two other such gardens were shortly established in the City, although by 1700 they all were under the direction of James Sutherland, the professor of botany. The enfranchisement of the subject from its dependence on medicine was indicated by the creation in 1768 of a chair of botany separated from that of materia medica, and the first holder of that post, John Hope, was a gifted botanical teacher, foreshadowing, in his classes of dissection and other practical work, the great biological advances to be made by Thomas Henry Huxley and his London colleagues a hundred years later.

During the long period in which directorship of the Royal Botanic Garden and the chair of botany were vested in one post under the Crown it is interesting to note that, just as the two Hookers, father and son, directed the Royal Botanic Gardens at Kew for altogether fifty-four years, likewise in Edinburgh, between 1848 and 1921, the two Balfours, John Hutton Balfour and his son Isaac Bayley Balfour, controlled the fortunes of the Edinburgh chair for no less than sixty-eight years. Charles Darwin was himself initially an Edinburgh student and the elder Balfour's reign covered the period of publication and discussion of the Darwinian theory. Correspondingly, it was the role of the younger Balfour to bring to Edinburgh and establish there the modern schools of botanical thought fostered in the great German university departments in the latter part of the nineteenth century. Under this leadership and that of their successor, Sir William Wright-Smith, the Edinburgh Department and Garden built up its present outstanding reputation, notably associated with the collections of new species of flowering plants brought back from China and other parts of the Far East by such great botanical collectors as Forrest, Farrer, Wilson and Kingdon-Ward.

In thus recalling the greatness of Edinburgh botanists of the past it would be unseemly if I were not to refer to one of the greatest of Scottish botanists, Prof. F. O. Bower, for many years holder of the Glasgow chair, a great and inspiring teacher whose own research on the evolutionary relations of the non-flowering vascular plants brought him world-wide acclaim. Scarcely less important was the way in which he assembled the powerful Scottish team of palæontologists, Lang, Gwynn-Vaughan and Kidston among them, who paralleled in northern Britain the work of Scott, Oliver, Williamson and Seward in the south. Scottish botanists and Scottish gardeners played no small part in exploring the far parts of the world for plants of economic importance, scientific interest and horticultural value; many, fostered by the traditional Scottish love of education, have pursued distinguished careers overseas helping to guide and develop less fortunate countries—England, I should add, among them.

* Substance of the Presidential Address to the tenth International Congress of Botany held in Edinburgh during August.

We meet, then, in one of the great traditional centres of Scottish botany, and the Congress derives great pleasure from this: it is likewise deeply grateful to the two scientists who are heirs to this great tradition, Dr. Harold Fletcher, Regius keeper of the Royal Botanic Garden and our general secretary, and Prof. Robert Brown, the distinguished plant physiologist who is head of the University Department of Botany.

I chose to make the main theme of my address "Botany and the Community" because there is far too little realization by people in everyday life, by Governments, by the main mass of scientists, and even by botanists themselves, of how extremely important to the life of mankind the study of botany is. It is not understood in general what is meant by botany, nor how botanical science shares, and in some directions leads, advances in scientific thought, nor that it now is the basis of plant technologies of the greatest economic importance to the world.

People accept, as they must, the truth that virtually all the food supply of the world originates in the photosynthetic processes of green plants, and that the fossil fuels such as coal, petroleum and natural gas release in their combustion energy derived from the same process operating in past ages. This truth has been dulled by familiarity, but it remains one of the inescapable realities binding botanical science to the community of men. It has been this primary food relationship that has bound man to the plant kingdom from Palæolithic and Mesolithic times when the human being was a hunter, fisher and collector, dependent for survival on his capacity to comprehend his environment and successfully to recognize and use its resources. It has not been sufficiently noticed how much more close became the ties between man and the plant kingdom with the onset of what Gordon Childe called the "Neolithic Revolution".

With the cultivation of crops, their storage and regular yield, came the possibilities of fixed human settlements, the development of village, town and city life and all the attributes of civilization that arise therefrom. It is one of the most exciting outcomes of recent co-operation between botanists, archæologists and geophysicists that we can now point with certainty to the origins of agriculture in the Middle East in the seventh and eighth millenia before Christ, and can recognize the affinity between the grains the Neolithic farmers then grew and the wild progenitors of these crops. It has been recognized from Darwin's time onward that human selection, intentional and unconscious, must have continually modified the original stock of wild plants to confer on them the qualities which farmers require, that is to say ready germination, simultaneous ripening, easy harvesting, high yield and similar properties. It was not long before it was also understood that the associated weed plants must have suffered a similar selection and that many species, in the course of time, passed in one direction or the other, over the boundary between the useful crop plant and the undesired weed. What had escaped our notice, until it was recently pointed out by Prof. C. D. Darlington, is that the process of natural selection was not confined to the crops and weeds, but that from the onset of Neolithic agriculture the units responding to selection pressure were the new symbiotic systems themselves, the ecosystems constituted in various environments by man plus his crops and domestic animals. Just as crop plants were selected because they suited man, so conversely an efficiently adapted husbandry favoured given races of men. This was without doubt selection for botanical ability. It is not too much to say that built into the genetic make-up of all the races of men derived from this ancient agricultural background is a sympathy for and an understanding of plant life. One might speculate that many traits, recognizable still even in our present urban existence, stem from the same antique sources, among them the love of gardens and affection for the countryside.

Even possibly love of such poetry as I quote from Chaucer:

> "of alle the floures in the mede,
> Than love I most these floures whyte and rede,
> Swiche as men callen daysies in our toun.
> To hem have I so greet affecciouu,
> As I seyde erst, whan comen is the May,
> That in my bed ther daweth me no day
> That I nam up, and walking in the mede
> To seen this flour ageln the sonne sprede,
> Whan hit upryseth erly by the morwe;
> That blisful sighte softneth al my sorwe."

With these deep instinctual roots and with the basic nutritional dependence of human beings on plant growth, it is all the more to be regretted that there is so indistinct and erroneous a public idea of what the botanist of to-day is like and what his work amounts to. Let me briefly consider what has happened.

As the late Dr. Charles Raven has so convincingly shown, the change from the old world of superstition, alchemy and magic to that of the natural sciences must be sought in the seventeenth century, when the 'new philosophers' arose in Europe, and when the Royal Society of London and the great German Society 'Leopoldina' were founded. Between 1650 and 1705 flowered the genius of John Ray, prince of British botanists, whose works over the whole biological field provided the basis, and much more, for the nomenclatural and organizational leadership given to the world by the great Swede, Linnæus.

At the early meetings of the Royal Society and kindred bodies there were not lacking pioneer essays in the field of experimental botany, as witness the publications by Malpighi, Stephen Hales, Grew and others, including the much-neglected holder of my own chair in Cambridge, Richard Bradley; but, as we now see, the physical sciences had not then achieved the level of development that could make them effective tools in biological research. Meanwhile, on the foundations of the learning of materia medica there blossomed the great age of enquiry into the riches of the plant and animal life of the world. It was facilitated by expanding transport and increased exploration, by the general spread of education and by the introduction of such biological research tools as the microscope. By the discovery, description and publication of the floras of vast new areas of the Earth, and by the recognition and examination of classes of organisms hitherto not known, methodical and exact observation was developed and an intensive concern with plants was fostered. The mainspring of this activity remained (as it began) in man's natural instinct of curiosity and his conviction, to use John Ray's title, of "The Wisdom of God manifested in the Works of the Creation". The plant collectors of the nineteenth century, from the greatest of international explorers to the humblest working-men naturalists, jointly gave rise to the popular picture of 'the gentle botanist' searching the forest and shore with his black vasculum and hand-lens: such a man could well subscribe to the view of John Gerard, the herbalist, who wrote, with strange appropriateness to to-day: "Who would dangerously look up at the planets, that might safely looke downe at plants?".

It was this period and this tradition, fortunately by no means abandoned to-day, that witnessed the great triumphs of inductive science. From the detailed particular observation of a multiplicity of organisms and structures in relation to their environment arose the revolutionary hypothesis of evolution by natural selection, and such lesser but still great triumphs as the demonstration by Hofmeister of the underlying equivalence of the life-cycles throughout archegoniate and higher plants.

It was altogether natural that the testing and elaboration of the principles of evolution should now pre-occupy the minds of biologists: the systematic comparison of

organisms throughout the plant and animal kingdoms formed the basis of biological training, and palæontology expanded vigorously in the expectation of discovering 'missing links' in the evolutionary chains. Although our university and school text-books still bear the strong impress of this phase of biological development, it has now come to occupy a much smaller part of our active interest than formerly it did. It is not so much that the problems have been solved, or interest in them diminished, but rather that the problems have proved too difficult of solution by methods now available, and enquiry has turned to more immediately rewarding topics.

It was the new problems and the new approaches to botanical science originating at the close of the nineteenth century and gathering impetus and importance throughout the twentieth that have transformed the aspect of botany, and given the botanist of the 1960's his present-day scientific personality. Put briefly, this modern development of botany is a constant progression towards the experimental and quantitative investigation of plant life, towards the investigation of all botanical processes in terms of causation and mechanism, an approach which, I need scarcely add, involves the application to biological problems of all the resources available from the physical sciences as well as those of related biological disciplines.

Although in the second half of the nineteenth century some advance had been made in this direction, especially by the German plant physiologists, the opinion persisted that 'vital' phenomena obeyed laws other than those of the physical sciences. The contrary view, urged with particular skill by Dr. F. F. Blackman in the first decade of this century, is now completely taken for granted, and it has been triumphantly vindicated by such discoveries as those of Crick, Kendrew, Watson and Watkins, of the molecular constitution of the chromosomes and the manner of their operation in the living cell. At last the cycle of development has now brought the physical sciences to a condition in which they can be effectively applied to the intensely complex phenomena of the living cell, as we can well see in the rapid development of the fields of plant physiology, plant biophysics and biochemistry which bring into their service all the complex techniques and elaborate apparatus of modern biology.

Not only to plant physiology are these exacting standards and techniques of the physical sciences applied: plant geneticists use radioactive elements both to induce mutations and to trace the processes of inheritance, and even so unlikely a subject as biogeography—called by Darwin "that grand subject, that almost keystone to the laws of creation", is using the techniques of radiocarbon measurement and of mass-spectrometric oxygen isotope assay to obtain absolute dates and palæotemperatures for the floras of past times, while its own discoveries are linked with the progress of palæomagnetic research into the fascinating history of the movements of continents about the Earth's surface. As botanists increasingly accept the dictum long since propounded by Lord Bacon that "Many parts of nature can neither be invented with sufficient subtilty, nor demonstrated with sufficient perspicuity, nor accommodated into use with sufficient dexterity, without the aid and intervening of mathematics", so we now find that problems of the natural ranges of plant species are successfully attacked by the use of electronic computers; we have had an *Atlas of the British Flora* produced by the application of mechanical data processing, sorting and printing, and in universities and research institutes highly exacting standards of statistical procedure are commonly used in analyses of plant growth and crop yield.

Plant taxonomy, the discipline which provides the essential nomenclatural basis for botanical science, has profited from improved microscopic techniques, from the findings of genetics and cytology, and from biochemical investigations based on the powerful use of chromatography, so that the phenols, tannins, alkaloids, to mention but a few, can be identified in their varied occurrence throughout families, genera and species of the higher plants.

Herbaria of dried plants came to be the standard equipment of plant taxonomists because the vast arrays of facts concerned in taxonomy could only be co-ordinated and correlated when convenient re-examination of the plant material could be arranged for. There never was any doubt that living specimens of plants provided yet more features of importance for taxonomic investigation, but although type collections of living micro-organisms have come into being, it has never been possible to maintain more than small specialist collections of living plants for taxonomic examination over long periods of time. Now, however, the recording and analysis of many features of living plants can be facilitated by mechanical and electronic means, which place at the disposal of the taxonomist vastly more facts than he has hitherto been able to encompass, and which create an effective agency both of storage and retrieval of taxonomic data.

How far, we may ask, can the same devices be used for assessing the information, how far can they work out correlations between the attributes that have been coded, and how helpful can they be in indicating classifications that arise from such correlations? These are questions that arouse passions in the bosoms of the most 'gentil' of botanists, nor can we expect any early agreement on such issues. Meanwhile, what I take to be an altogether outstanding service has been done, both to botanical taxonomy and that of all other organisms, by a group of biologists examining afresh the philosophical basis on which both classification and taxonomy rest. It is their contention, that I think is scarcely to be denied, that many natural classifications can usefully and properly be made of any group of organisms, and that not only has a phyletic classification no claim to be called the only natural classification, but also that phyletic classification is so difficult to determine objectively that it ought no longer to dominate systems that are primarily needed simply for purposes of nomenclature. Each natural system of classification according to them has its own validity, and it is correct and useful just so far as it discharges the purpose for which it has been set up. Prof. H. Bondi has written:

> "Now what is clear from all that has been said about the nature of science is that scientists must be able to *communicate* with each other. One cannot stress too strongly that the mystic who sees things clearly in his own mind, but cannot transmit this information to others, is not a scientist. The making of discoveries, the original act of thinking up a new theory, is in no sense a more valuable contribution than its transmission to others. It is only by making known what one thinks that it can be checked and cross-checked by others, and it is in this process of communicating for the purposes of checking that the essence of science lies."

It is the purpose of international congresses to foster this communication and clarification.

We now turn from consideration of the nature and present pre-occupations of the botanist of to-day to those relationships with the everyday life of the world which are implied in the title of my address. Any survey of the world's present food position must commence from the generally accepted opinion that the world population will have doubled by the end of this century, and that by A.D. 2000 food production must correspondingly double if it is to do no more than maintain the world's present inadequate standards of nutrition. All biologists will agree that the final solution to this problem of expanding populations must be limitation on the rate of production: failing this the population pressures must ultimately result in famine, revolution and war. Meanwhile, however, we can, by the extension and improvement of the techniques of food production, do an immense amount to

overtake the world's needs and contribute to the relief of hunger and starvation.

It is not generally understood how large a part the botanist has already played in the improvement of the practices of agriculture, horticulture, fishing and forestry, nor how vital is the maintenance and development of the great fields of plant technology that are associated with these industries. The nature and scope of these plant-technological activities are admirably outlined in the pamphlet written by Prof. A. J. Riker on behalf of the U.S. National Academy of Sciences and distributed to all members of this Congress. Although written in respect of botanical activity in the United States *, this pamphlet, *Some Opportunities and Challenges in the Plant Sciences*, has relevance throughout the botanical world. It is especially appropriate that attention should be paid to such issues during this Congress in view of the organization under the auspices of Unesco of the International Biological Project within which biologists in all countries will concentrate on increasing the organic productivity of the world and conserving its natural resources.

We now take almost for granted the services of plant physiology to the investigation of crop growth, of mycologists and plant pathologists to the constant protection against fungi and bacteria of food growing in the field or kept in storage; we have accepted and almost forgotten that the origin of the vast new industry of weed control by selective herbicide was in the botanical investigation of the natural growth substances of plants. In our present plight the potentialities of the breeders of crop plants can scarcely be over-estimated. The botanists of the new world, by the introduction of hybrid corn, at one step immensely increased the production of maize, and a recent symposium on wheat genetics revealed the astounding virtuosity of the plant breeders, who, basing their work on the fundamental cytogenetic investigations of the past, locate and transfer from species to species, even from genus to genus, the genes controlling yield, adaptability and disease resistance. As the organic chemist can now claim to tailor the molecule, so the wheat geneticists tailor the chromosomes of that cereal on which so much of mankind depends for food. It is a far cry from the selection of wild grasses by the Neolithic agriculturists of the 'Fertile Crescent' eight thousand years ago to the wheat genetic conference in Lund; but the mutual dependence of man on the cereal crop has become not looser but more compelling. The challenges grow greater, not less, and great fields of enquiry lie open before us. To mention two only, the productivity of the oceans on one side, and that of the arid deserts on the other, have barely yet been affected by scientific research. The Governments of the world carry a great responsibility to maintain and extend botanical research both pure and applied: they will neglect it at their peril.

It is evident that biological science and botanical science are indispensable to our complicated material civilization and that technical advances depend on maintaining them, but this is not the only reason why the world requires them. Sir Arthur Tansley, writing of the whole discipline of science, said that its practice involved "intellectual, ethical, æsthetic and ultimately spiritual values of a high order". He sought for scientific teaching to take a permanent and unquestioned place in the education of peoples throughout the world, not merely because it lies at the root of successful technology and material prosperity, but also because it has cultural values of its own, values not conferred by the older traditional systems that we still largely follow. He wrote, and all would, I believe, endorse his view: ". . . There can be no doubt that the scientific habit of mind, with its insistence on preliminary careful and accurate survey of facts and its constant testing of theory by fresh observations and experiments, is the master-key to the devising of successful techniques, not only in the material but in the social and political spheres", and he continues: "Equally with literature and art, science has its own contribution to make to the development of the mind, its own distinctive quality engendered by the habit of dispassionate objective investigation and of respect for objective truth".

The need constantly to distinguish ruthlessly between what is and what is not known conditions an ability in all educated scientists to recognize the limits of established knowledge and to admit 'we do not know' in the all-too-frequent situations where this is called for. The exercise of such standards in pursuit of the biological sciences is still more exacting than in the physical sciences; but the aptitude, so far as it can be acquired, has then even more relevance in its applications to everyday life, since we are ourselves not the least complex of living organisms. For this reason I suggest that there has to be a substantial biological content in the education of any and every cultured man or woman, and for such purposes I rate the botanical content equally valuable with that of other biological disciplines.

I have attempted to express something of the responsibility which botanists must accept towards the pressing needs of the world: they will be better able to accept and discharge these responsibilities by meeting together as in the tenth International Congress of Botany. Likewise, this Congress permits us to point to the reciprocal responsibility of peoples and Governments to sustain and encourage botany both at the level of research and as part of a balanced general education.

Finally, allow me to recall that Sir J. J. Thomson, one of the most eminent of physicists, towards the end of his life remarked that if he were to start again he would study botany, for he considered that subject to be at a stage of development comparable with that of physics in the days of his youth The recent progress not only of botany, but also of biology, confirms that great physicist's insight: the field of botanical research is open to the ablest of scientific minds and will provide problems for them not only of the greatest intrinsic interest, but problems which in practical application are vital to the prosperity and even to the future existence of mankind.

* Reprint from *AIBS Bull.*, 12, No. 2 (April 1962).

THE FUTURE OF BOTANY

IT is something of a paradox that, at a time when the learned journals dealing with the plant sciences are struggling to cope with the demand for the publication of an increasing flow of high-class contributions, when botanists are bombarded by a growing complex of review articles and "Recent Advances" and when thousands of botanists can gather at a Congress devoted to innumerable discussions of developments in their subject which are often spectacular, there is still felt in many quarters a profound disquiet concerning both the support at present being given to botany and the prospects for the future.

In a memorandum prepared for the U.S. National Academy of Sciences and collated by Prof. A. J. Riker of the Department of Plant Pathology, University of Wisconsin[1], the case is made that the examination of plants has conferred on mankind so many benefits now considered indispensable, and that the future of civilization will be so conditioned by the rate at which plant science develops, that it is inconceivable that the fullest support

should not be given to botany and to botanists here and now. In point of fact, however, in most parts of the world at least, and the United Kingdom is one of them, botany is invariably, of the scientific disciplines, the one to receive the least support either by way of research facilities or of new buildings and—much the more important—to be the least well provided with students of the requisite quality in the requisite numbers.

At the tenth International Botanical Congress held recently in Edinburgh occasion was made to look into the extent of this public neglect of botany and into the possible reasons for it, with particular concern for the responsibility which botanists themselves must accept for the evils of the present situation, at a general meeting, under the title: "Botany; the Present Crisis and Future Prospects".

At the meeting concerned, four main speakers, Prof. W. O. James (Great Britain), Prof. K. V. Thimann (United States), Prof. A. J. Riker (United States) and Prof. T. S. Sadasivan (India), dealt in turn with various aspects of the problems and afterwards there was a lively discussion among the large number of botanists attending. As a result of this meeting it is abundantly clear that there is among botanists world-wide disquiet about the situation of botany. The reasons for this disquiet are, as might have been anticipated, not completely identical in the 'developed' countries and in the 'underdeveloped'. By and large, the underdeveloped countries look to the developed countries for help in establishing the modern expensive lines of investigation, and their needs will not be discussed further here, for representations have already been made elsewhere in another context. If, however, the developed countries are to accept the challenge of the underdeveloped, as they must, this can only be done if their own botanical institutions are flourishing abundantly. This is all the more reason why the developed countries should look to their own households.

Perhaps the major point which was made during the discussion, and this came out again and again from both the developed and the underdeveloped countries, was the faulty image of botany prevailing in the schools, among non-botanists even in universities, and presented to the public. This is the long-standing concept of an amiable individual, vasculum on shoulder and lens in hand, pottering ineffectively among the flowers of the field. It is to a large extent the modesty of botanists which has allowed this image to persist so long, and this was pointed out most forcefully, particularly by Prof. Thimann. In this, as in many other matters, the meeting warmly supported views already so admirably expressed by Prof. Godwin in his address (p. 10 of this issue).

It is self-evident that living plants have all the complexity found in the inanimate world together with many special tricks of their own. It therefore follows that in addition to the well-established, and quite indispensable, 'classical' approaches to botany, the whole range of techniques and lines of thought characteristic of modern physics and chemistry are vital also in plant science. These are indeed assimilated into botany as rapidly as they become available wherever and whenever finances permit, as eloquently testified in the general lectures at the Congress and in very many papers read in the scientific sections. Far from being a 'soft option' for students, botany is the most demanding of the sciences and therefore the most rewarding, with requirements ranging from meticulously careful observation, collection and classification of field results to the most exacting physical and chemical determinations in the laboratory and interpretation reaching as far as established physical principles will allow. Several speakers made the point that botany therefore comprises a range of interests which will meet the intellectual needs of a wide range of student interests. The trouble seems to be that the interest of really good students is not caught at a sufficiently early age, if it is caught at all, so that, with comparatively rare exceptions, they pass to other disciplines unaware of this rapidly developing subject.

Part of the neglect of botany in this and in other ways clearly stems also from a common ignorance of the debt owed by the community to applied botany, and this again may be in part a consequence of the undue modesty of botanists. To quote examples given by Prof. Thimann, among the many which could have been documented and some of which were documented by Prof. Godwin in his address (p. 12), how many now recall that the whole rubber industry dated from plants of *Hevea brasiliensis* grown by Sir Joseph Hooker in the greenhouses at Kew Gardens, of which he was director, and sent by him to Ceylon, where they thrived; or that the distribution of seeds from this and other plants in South East Asia was made possible only by the investigations of the botanist Ridley? How many recall, or even know, that streptomycin was brought to light by the botanist Waksman, chloramphenicol by the botanist Burkholder, and the tetracyclines by Duggar? Very many such modern drugs are, in any event, not synthetic but 'botanical', and this makes it difficult to express any sympathy for the present-day neglect of botany by organized medicine with its consequential encouragement to schools to minimize the need for extensive botanical teaching.

There is no doubt that the next major breakthrough in science will be in biology, and in the view of Prof. Riker, and many of us, botany will at least play its fair part. If this breakthrough is to come quickly and effectively, all the developed countries will need the right people in the right numbers to meet the challenge both in their own communities and in those less well favoured. Only a far-sighted national policy providing university entrants of high quality in greater numbers than now, and giving botany departments ample facilities both for teaching and research at the exacting standard demanded, can achieve these ends; and it is not obvious that Britain has any policy at all. This was a point instanced by Prof. James and many other speakers.

The view was expressed, moreover, over and over again that a national policy should be based not only on the practical value of botany, which is undoubted, or on the intellectual challenge it gives to its exponents; note should be taken of the value of botany in bringing man close to his natural surroundings and in exercising his mental capacities to any limit they can reach; it is a discipline to which all young people should be exposed as part of their necessary education. Perhaps the best way of inducing intelligent young people to expose themselves to the challenge of botany is for professional botanists themselves to present to them the excitement of working in this expanding field, and opportunities should be made, and taken, to this end.

Finally, concern was expressed by several speakers, including Prof. Sadasivan, that botanists are not at present being adequately employed either in industry or in research associations. It is quite obvious that physicists and chemists are employed in considerable numbers in duties which properly call for botanists. Some of them are indeed coming into botany as professional scientists working on fundamental problems in botany, and these are to be welcomed and encouraged by every possible means. But they bring dangers; dangers arising, for example, from an unrecognized complexity in their experimental material and from unawareness of the wide variations of which the immediate material may be only one. There is no avoiding the need for botanists trained in the standard methods of botanical investigation and experienced in the application to plants of modern physical and chemical, and even mathematical, methods. Industry should, moreover, become aware of the versatility of well-trained botanists and their consequent value in research laboratories as well as in the field. R. D. PRESTON

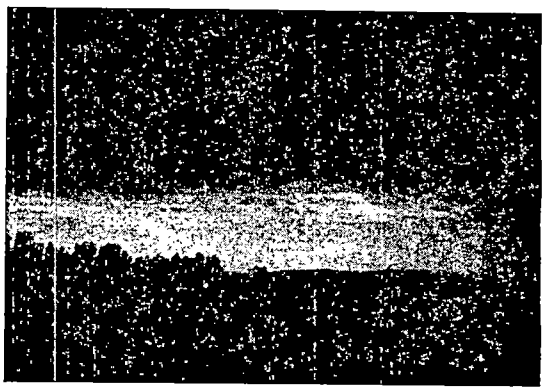
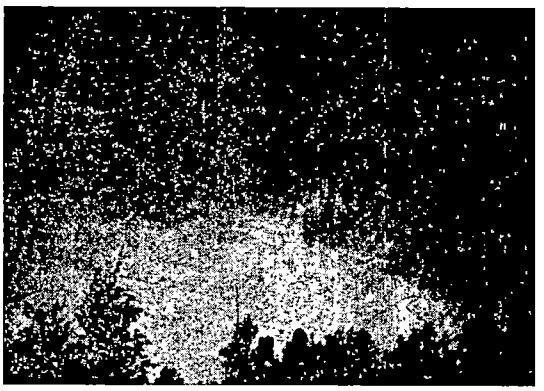
NOCTILUCENT CLOUDS IN THE SOUTHERN HEMISPHERE



By BENSON FOGLE
Geophysical Institute, University of Alaska, College, Alaska

NOCTILUCENT clouds are occasionally seen in high latitudes during summer months. They are a beautiful sight to behold, as those who have observed them will readily affirm. Several photographs of the clouds appear in Fig. 1.



The study of noctilucent clouds was begun in the year 1885 by Jesse in Germany and Tseraskii in Russia. Since then hundreds of observations have been made from Alaska, Canada, Europe, and Russia. During this same period, however, only three displays have been reported

from the southern hemisphere, and this scarcity of reports, along with the uncertainties associated with them, cast considerable doubt on the occurrence of noctilucent clouds in southerly latitudes.

Characteristics of Noctilucent Clouds

Among the characteristics established during the past 80 years are the height, cloud particle size, the number of particles/c.c., time of year and time of day when they can be observed in the northern hemisphere, and the temperature of the mesopause when the clouds are present. The cloud height is between 79 and 87 km, the average being 82 km[1]. The temperature at this altitude, when noctilucent clouds are present, is about 130° K (N.A.S.A. News Release No. 62–248).

Statistics on the occurrence of noctilucent clouds over the northern hemisphere show that they occur most often during July and August, although they have been observed as early as March and as late as October. Most of the observations have been made after the summer solstice. Naturally occurring noctilucent clouds have been observed only in the latitude range of 45°–77°, the optimum region being 50°–65°. They can be observed visually only during the twilight periods of the day when the Sun is between 6° and 16° below the horizon. The particle density in noctilucent clouds has been estimated to be between 1 and 10^{-2} particles/cm^3 (ref. 1). The average radius of these particles has been determined to be about $1{\cdot}4 \times 10^{-5}$ cm (ref. 2). The results of rocket-sampling experiments conducted in Sweden during 1962 showed that: (*a*) the particles in noctilucent clouds ranged in diameter from 5×10^{-6} cm to 5×10^{-5} cm; (*b*) the larger particles were coated with a volatile material believed to be ice; (*c*) the dust nuclei contained traces of nickel and iron, indicating that they are of extra-terrestrial origin; (*d*) the particle density at the mesopause was found to be greater by a factor of 100–1,000 when noctilucent clouds were present than when they were absent[3].

Southern Hemisphere Observations

Since 1885 there have been only three reports of noctilucent clouds from the southern hemisphere. The first report was made by a ship's captain about the year 1886[4]. His ship was located in the Beagle Channel (54·5° S., 68° W.) off Punta Arenas, Chile, at the time the observation was made. The exact date, time, direction, and characteristics of this sighting were not given in the report. The second sighting was reported by Herr Stubenrauch[4] in December 1888, from Punta Arenas, Chile (53·5° S, 71° W.). Again, the exact date, time, direction, and characteristics of this sighting were not given. The third sighting was reported by Mr. W. Holman on the night of December 4–5, 1962 (private communication). His observation was made from the U.S.N.S. *Eltanin*, which, at the time of the observation, was located south-east of Tierra del Fuego at 55° S., 58·8° W. Mr. Holman attempted to photograph the clouds but was unsuccessful. Since none of these observations was well documented, there is some doubt as to their reliability. Thus the question of whether noctilucent clouds do occur in the southern hemisphere is still an open one. If they do occur, there are the supplementary questions of their frequency of occurrence, height and latitudinal distribution.

Based on the observational data from the northern hemisphere, which gives a maximum of noctilucent cloud activity in the summer months of June, July, and August, one would expect that, if they occur in the southern hemisphere, they would most likely be seen in the months

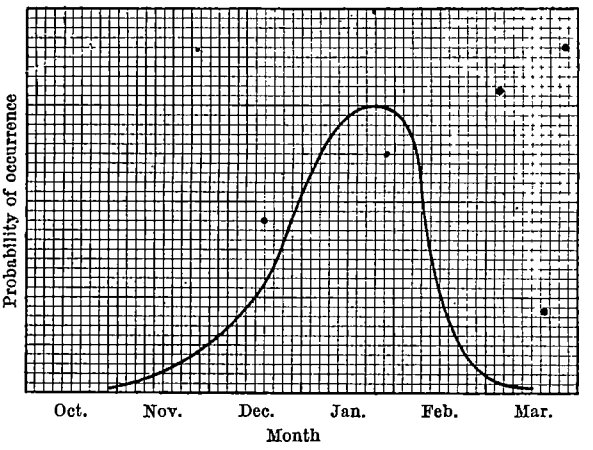

Fig. 2. Expected probability of occurrence of noctilucent clouds in the southern hemisphere

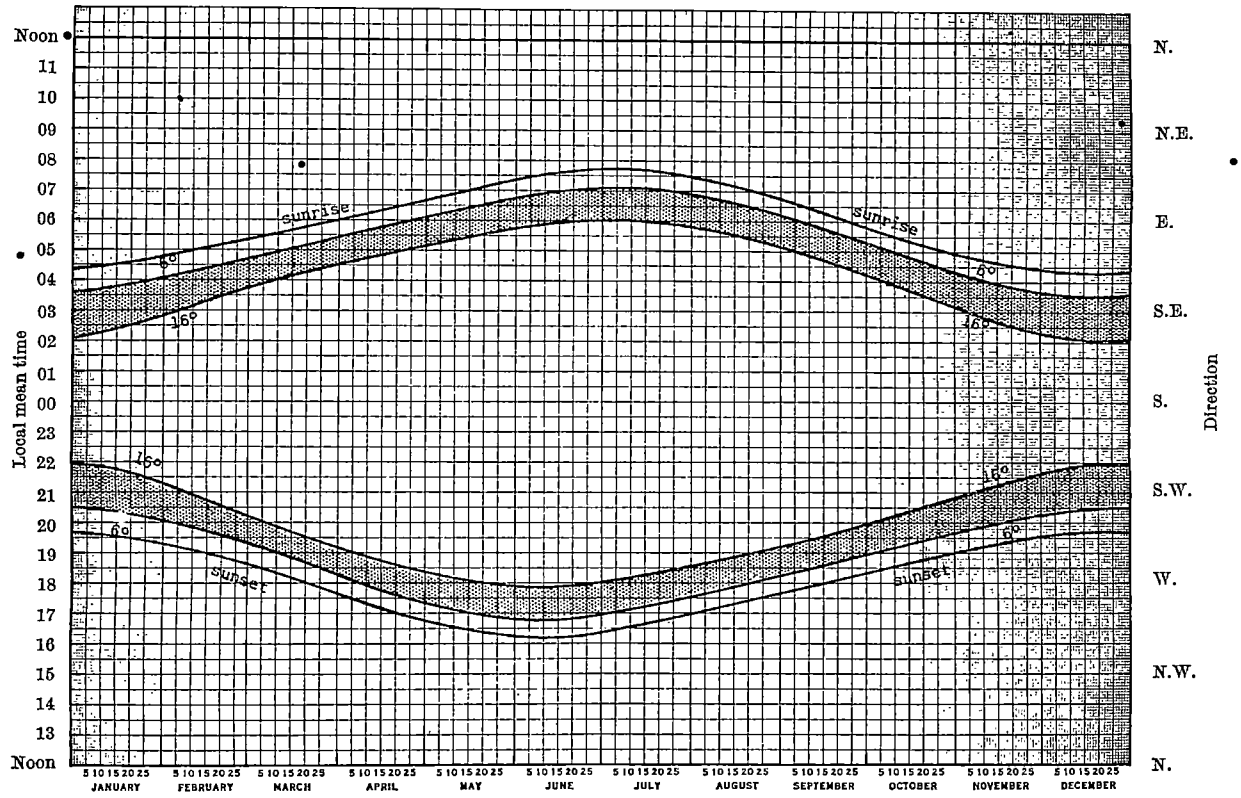

of December, January, and February (Fig. 2). Observers in the latitudes 45°–70° S. should stand the best chance of seeing these clouds. The times for observing noctilucent clouds from these latitudes are shown in Fig. 3.

In contrast to the northern hemisphere, there is very little inhabitable land and a corresponding scarcity of people in the region 45°–70° S. There are, however, some locations in these latitudes that are well situated for observing noctilucent clouds. These locations are tabulated in Table 1.

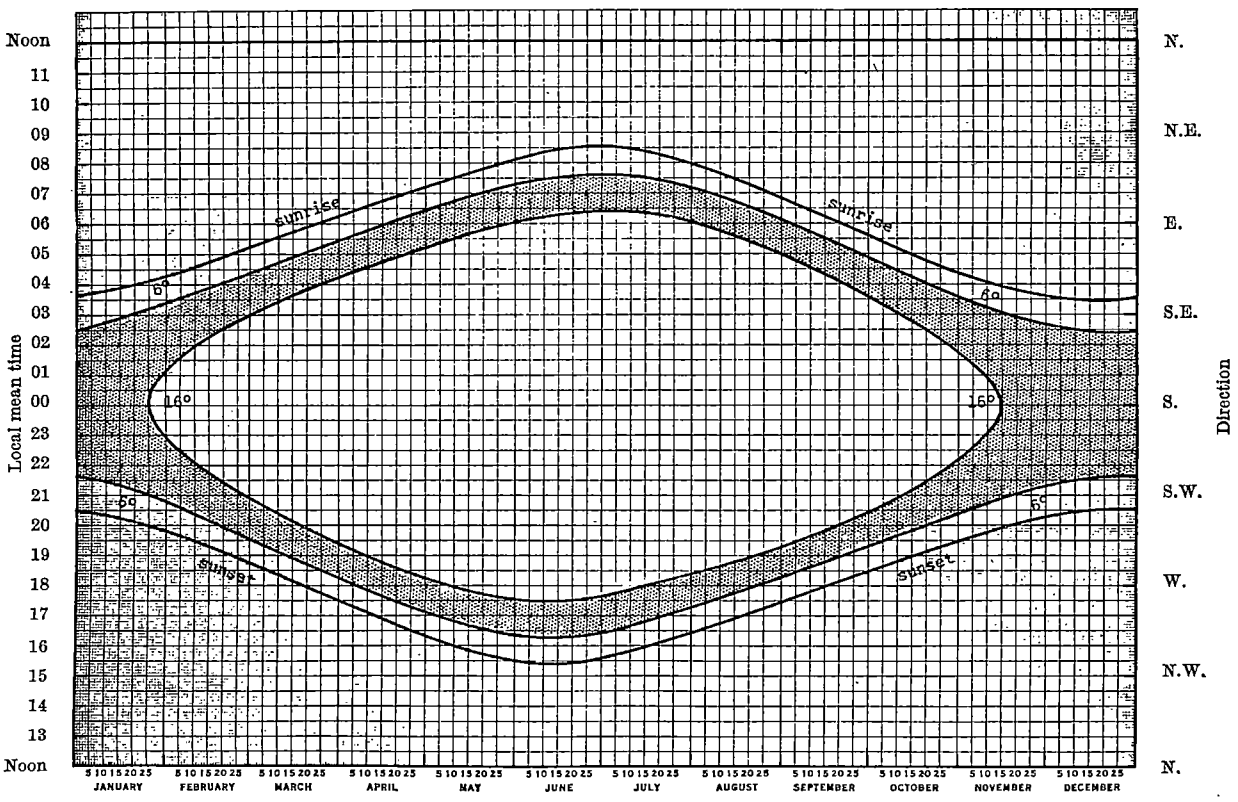

Table 1. Southern Hemisphere Stations that are well situated for Observing Noctilucent Clouds

Station	Sponsor country	Geographic co-ordinates Latitude	Longitude
1. Lauder	New Zealand	45·0 S	169·7 E
2. Invercargill	New Zealand	46·4	168·3 E
3. I. Crozet	France	46·5	52·0 E

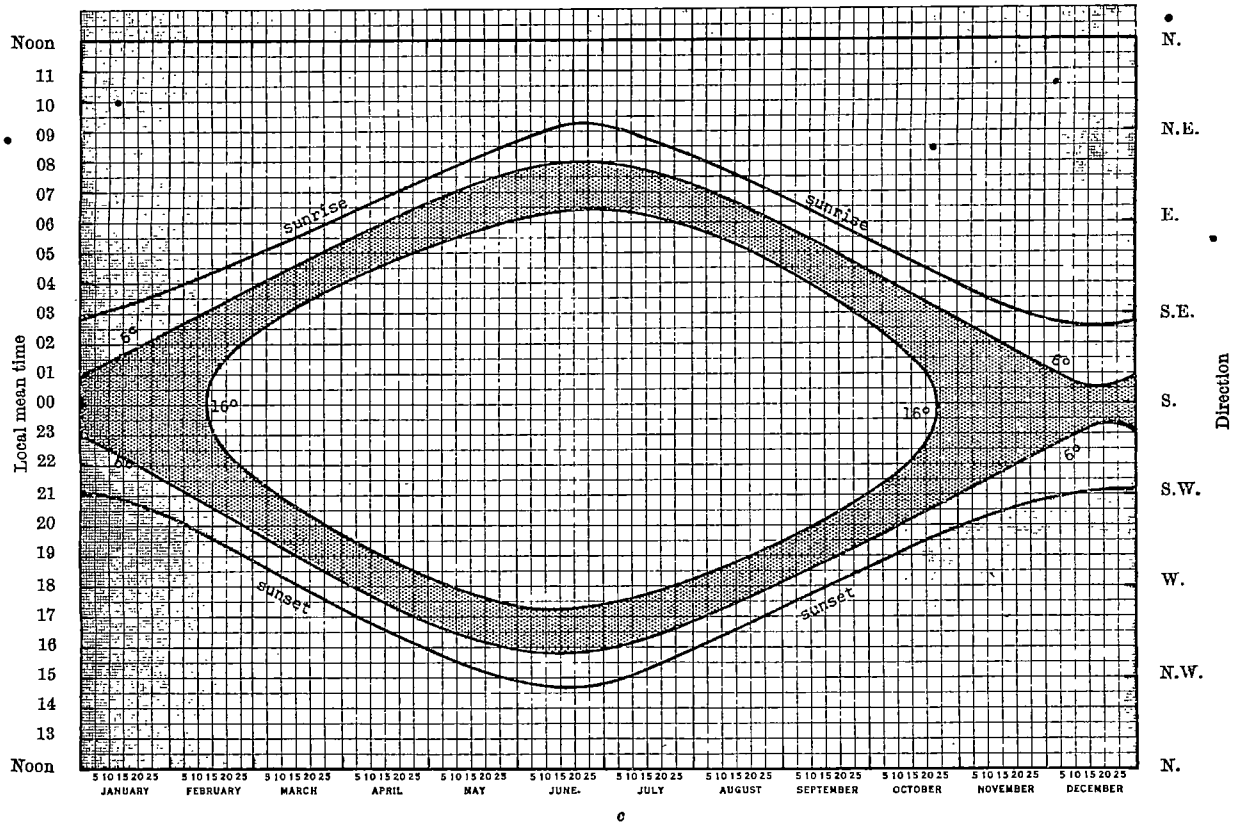
8. Port Stanley	United Kingdom	51·7	57·9 W
9. Campbell Is.	New Zealand	52·5	169·1 E
10. Heard Is.	Australia	53·0	74·0 E
11. Punta Arenas	Chile	53·5	71·0 W
12. McDonald Is.	Australia	54·0	74·0 E
13. Grytviken	United Kingdom	54·3	36·5 W
14. Macquarie Is.	Australia	54·5	158·9 E
15. Ushuaia	Argentina	54·8	68·3 W
16. South Georgia	United Kingdom	55·0	37·0 W
17. Orcadas del Sur	Argentina	60·8	44·7 W
18. Deception	Argentina	63·0	60·7 W
19. Esperanza	Argentina	63·4	57·0 W
20. Teniente Matienzo	Argentina	65·0	60·0 W
21. Argentine Is.	United Kingdom	65·3	64·3 W
22. Wilkes	Australia	66·3	110·5 E
23. Dumont d'Urville	France	66·7	140·0 E
24. Mawson	Australia	67·6	62·9 E
25. Davis	Australia	68·6	78·0 E
26. Sanae	South Africa	70·3	02·4 W



To answer the question about noctilucent clouds in the southern hemisphere, an effort is being made to establish a network of observers in those regions to keep a watch for these clouds. The weather observers at the U.S. Antarctic bases are already participating in this programme, but they are unfortunately outside the optimum latitude range for seeing the clouds frequently. A noctilucent cloud observation manual has been prepared[5] to familiarize these observers with the phenomenon, and is available on request to me.

A NEW JOINT AMERICAN–AUSTRALIAN ASTRONOMY CENTER

By Prof. T. GOLD* and Prof. H. MESSEL†
Cornell–Sydney University Astronomy Center

Introduction

A NUMBER of important research programmes in astronomy would be considerably more effective if they were carried out in both the northern and southern hemispheres by one and the same group of scientists freely using a variety of integrated major astronomical instruments. It is likely that future developments in astronomy will increase the need for such observations—and, in fact, one may expect that some of the more significant work in this field of research will result from such large-scale programmes. These programmes will require the efforts of a very large group of scientists with experience in a number of astronomical and related fields.

Astronomical research in universities has suffered in the past from the fact that astronomers have usually worked in groups of 'sub-critical' size. This has sometimes led to difficulties in regard to staff recruitment, attraction of young postgraduate workers to the field, to the difficulty of raising adequate funds for the construction of a major facility and also of making full use of the facility after completion. Considering these difficulties in conjunction with the rapidly increasing capital costs and size of astronomical installations, plus their running and maintenance at widely separated geographical positions, it is evident that no present single university could effectively undertake a programme of the type envisaged here. This applies to efforts within any one single country and even more so if one considers operating in both hemispheres.

The problems for universities, arising from running a large basic research facility at a great distance from a university centre, are well known. Especially important is the danger of a resulting intellectually isolated research facility which then loses touch with university teaching—and finally fails to provide for the adequate training of postgraduate students.

However, it is now generally agreed that research and postgraduate education of young scientists are intimately related—and hence the function of the universities, whether it be in the costly field of radio astronomy or some other. This fact is vital and has not always been taken sufficiently into consideration when deciding on the administrative abode of important astronomical installations. The resultant world-wide shortage of young astronomers, and especially radio astronomers, is well known and requires urgent efforts to rectify it.

As a helpful step in this direction it is proposed that scientists working in the astronomical and related fields at Cornell University and the University of Sydney, Australia, pool their already individually considerable resources in regard to manpower and equipment in a joint university astronomy programme spanning both hemispheres.

The only major initial costs associated with the scheme are those concerned with travel and living expenses. These, however, will be small in relation to the capital invested in the installations themselves and their running costs, which amount to approximately two million dollars annually at present.

* T. Gold, Center for Radiophysics and Space Research, Cornell University, Ithaca, New York, U.S.A.
† H. Messel, School of Physics, University of Sydney, Australia.

The Joint Programme

At present both universities have major new astronomical installations either completed or nearing completion and a number in an advanced planning stage.

The University of Sydney stellar intensity interferometer under Prof. R. Hanbury Brown, at Narrabri, New South Wales (Fig. 1), has commenced operations, and first results on the angular size of Vega have been published. The University's large Mills Cross under Dr. B. Y. Mills, at the Molonglo Observatory at Hoskinstown, New South Wales, is nearing completion and observations will be under way by the end of 1964. The capital cost of these two Sydney School of Physics facilities alone will be more than two million dollars. Major financial support has been or is being provided for these projects by the U.S. Air Force Office of Scientific Research, the U.S. National Science Foundation, the Department of Scientific and Industrial Research of Great Britain, the Nuclear Research Foundation within the University of Sydney and Mr. S. E. Chatterton of Sydney, Australia.

In addition the University of Sydney's Electrical Engineering School, with Prof. W. N. Christiansen as its head, has a field station at Fleurs, about thirty miles west of Sydney. This field station—which was given by the Australian Commonwealth Scientific and Industrial Research Organization—contains the 1,420-Mc/s grating cross with sixty-four 19-ft. paraboloids, commonly known as the Criss Cross, the original 1,500-ft. × 1,500-ft. Mills Cross operating on 85 Mc/s, and the Shain Cross operating on 19 Mc/s. Additions to the Criss Cross are being built and the Shain Cross is at present undergoing modifications.

The giant 1,000-ft. radio and radar instrument in Arecibo, Puerto Rico (Fig. 2), has just been completed at a cost of nine million dollars as part of the Advanced Research Projects Agency 'Project Defender'. Known as the Arecibo Ionospheric Observatory, it has been constructed and is being operated by Cornell University under contract with the U.S. Air Force's Cambridge Research Laboratories and Office of Scientific Research. Although designed primarily for the investigation of the ionosphere, it may have even greater basic scientific interest in radar and radio astronomy, owing to the great power and gain required for the ionospheric programme. Observations with it are under way, under the direction of Prof. W. E. Gordon, and already many important new results have emerged.

In addition to the astronomical instruments, both universities have closely related cosmic astronomy installations which would be included under the proposed arrangement. The installations, which are supported largely by the U.S. Air Force Office of Scientific Research and the Nuclear Research Foundation (Sydney), are under the direction of Prof. K. Greisen of Cornell University and Prof. C. B. A. McCusker of the University of Sydney. Further, both the university groups have direct control of, or call on, a very wide range of necessary supporting staff and facilities. For example, the University of Sydney School of Physics recently installed a new high-speed computer in order to be able to cope with the large amount of data which will be forthcoming from its new astronomical instruments.

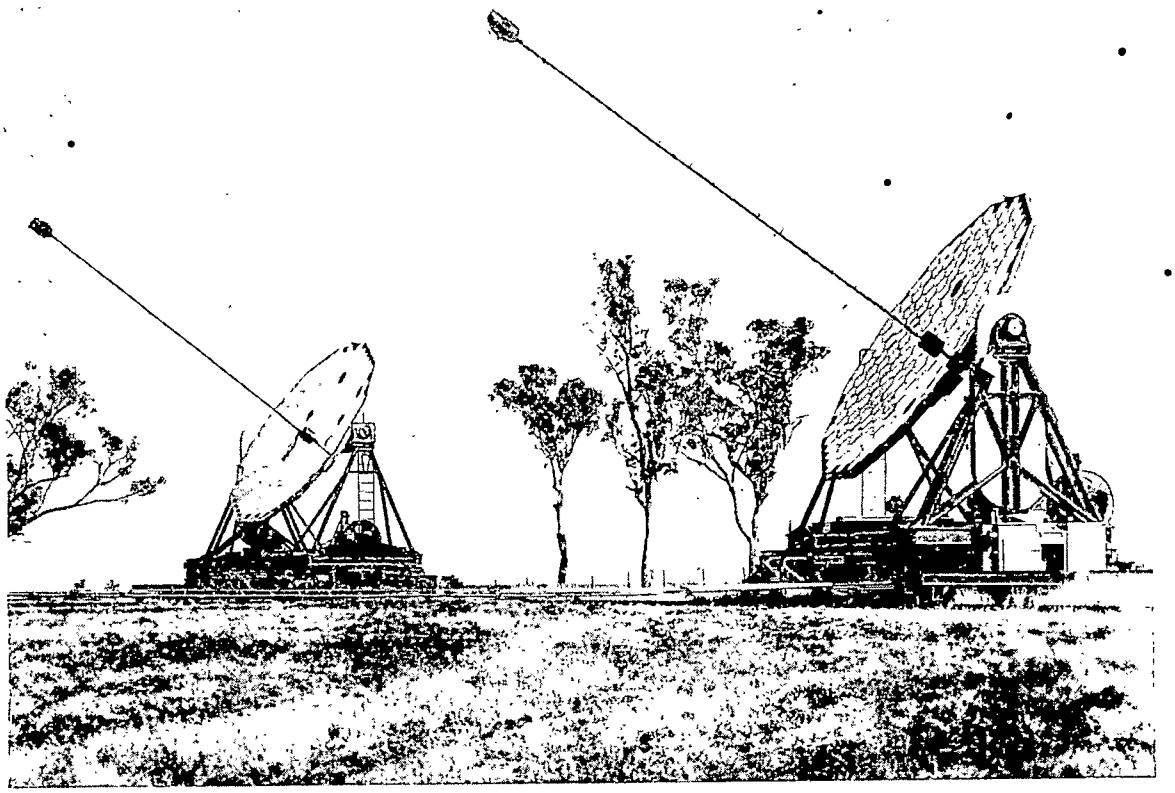

Fig. 1. The two mirror units of the stellar intensity interferometer at the Narrabri Observatory some 350 miles from Sydney

Members of the Centre agree to pool for the use of the Centre all the astronomical facilities—and facilities closely associated with these—under their direction or control. At Cornell the scientists concerned are the members of the Cornell Center for Radiophysics and Space Research under the direction of Prof. T. Gold; at the University of Sydney those concerned are the members of the Chatterton Astronomy and Falkiner Nuclear Departments in the School of Physics under the direction of Prof. H. Messel and the Sydney University Electrical Engineering School under the direction of Prof. W. N. Christiansen. The joint operation is proposed under the direction of Prof. Messel and Prof. Gold, who will be the Centre's joint directors.

Senior members in Sydney include R. Hanbury Brown, W. N. Christiansen, C. B. A. McCusker, B. Y. Mills, A. E. Aitchison, I. S. Docherty, E. A. S. Finlay, A. G. Little, M. I. Large, C. T. Murray, H. D. Rathgeber, M. M. Winn, L. R. Allen, J. Davis, K. S. Imrie, W. B. McAdam, R. F. Mullaly, H. S. Murdoch, L. S. Peak, A. J. Turtle and R. Wielebinski.

At Cornell there are E. E. Salpeter, P. Morrison, K. I. Groisen, G. Pettengill, C. Hazard, F. D. Drake, M. Cohen, W. L'Axford, M. R. Kundu, M. O. Harwit, J. P. Delvaille and B. Hapke.

All research carried out by the members of the Centre under this operation or work which benefited from it will appear under the title "Cornell–Sydney University Astronomy Center".

Both the facilities and scientists of the two universities will, as at present, remain administratively under their respective control; however, the facilities will be pooled for use by the joint group. New installations in the future could be placed under the administrative control of one or other of the universities or, if dictated by geographical position, under their joint control. The mode of operation will not interfere with any research priority system which may be in effect at a facility, but it will merely increase the pool of staff available who may carry out such research.

It is envisaged under this plan that staff within the Centre would be completely interchangeable and that scientists from Cornell would spend considerable time in Sydney (Australia) and at the facilities of the Sydney group, and Sydney scientists would equally well spend considerable time in Ithaca (New York) and Arecibo (Puerto Rico). A knowledge of the different modes of operation and of various technical skills could thus be disseminated to the group as a whole. Technical and instrumental problems of any one facility would come to the attention of the entire group, and the knowledge, ingenuity and experience of all members would be available for their solution. Undergraduate and postgraduate lecture courses and seminars given by scientists of the sister institution would greatly expand the range of interests and knowledge both of faculty and students.

Graduate students would also be interchanged between the two institutions whenever appropriate for the research work on which they are engaged. They would, perhaps, be the most important beneficiaries of this scheme. In the first place, good prospective graduate students in both countries would more readily enter radio astronomy and associated fields if they saw the possibility of joining a group of such a wide range of knowledge and skills. They may develop a particular interest in the approach available in the other institution. As an example, at the present time insufficient training is available in the United States in such fields as phased arrays and interferometers and instruments of the Mills Cross type, and this is felt as a serious handicap in the development of new instruments in the United States. The Australian scientists do not have any planetary radar facility at their disposal. There are several other examples of this nature.

The scientific programme which would initially receive most attention under the joint operation would be the survey of discrete radio sources. This is the investigation of the statistical distribution of sources with the view of deriving information concerning the distribution in depth.

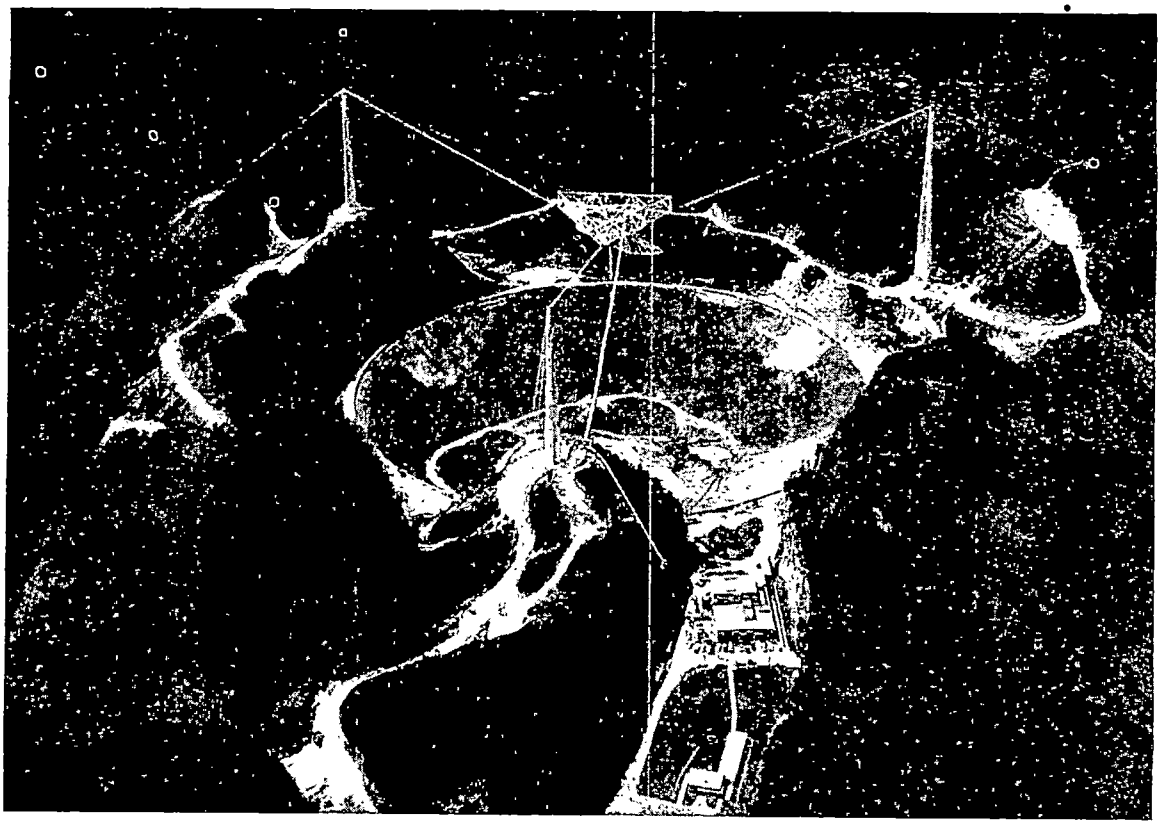

Fig. 2. Aerial picture of the giant radar radio telescope at Arecibo in Puerto Rico. The spherical dish antenna is 1,000 ft. in diameter and the movable feed arm is suspended on cables some 500 ft. above it from three concrete towers, two of which are 265 ft. in height and the third 365 ft.

It has been shown that such investigations have the possibility of giving information concerning the structure of the universe on the largest scale and, therefore, about cosmology.

Investigations of this kind have been made several times in the past, and have been severely disturbed by a variety of errors. It is now considered that such catalogues of sources ought to be published, so far as possible, only after each source has been investigated separately by two different instruments which are unlikely to suffer from similar deficiencies and which work on approximately the same frequency. A large area-filled instrument like a dish and an open area instrument like a Mills Cross make an ideal pair in this respect. It is proposed, therefore, to prepare a detailed catalogue of sources in the area of sky in which the Sydney Mills Cross and the Arecibo instrument overlap. All discrepancies between the results of the two instruments will be investigated in detail, and the final catalogue should be of a level of precision far exceeding that of any previous work.

Other investigations where a joint operation is clearly advantageous are those of extended sources and background structure where more detail can be described by using two such instruments than by either singly.

These examples of joint observation are those which come to mind in the present state of the instrumentation. It is expected, however, that many other types of observations will equally benefit as the subject advances and as the instrumental facilities available increase. Furthermore, one may look forward to new research projects coming forward as the full effect of the joint team effort comes to fruition.

The two universities have agreed to recognize research supervision extended by the sister institute and with the approval of the home research supervisor, and the time spent by a student on thesis work in the sister institute will be accepted toward the residence requirement.

The scientists concerned are agreed that such a joint operation would be most beneficial for their work and for the subject, for the reasons mentioned. An operation of this kind, where the advantages to research are conspicuous, may pave the way towards other combined university operations which tend to break down barriers imposed by geography and thus broaden the educational programme.

OBITUARIES

Dr. R. S. Creed

His many pupils will have read with regret of the death on July 7 at his home near Oxford of Dr. R. S. Creed, emeritus Fellow of New College, Oxford, and formerly demonstrator and lecturer in the Department of Physiology, University of Oxford. He was in his sixty-fifth year and is survived by his wife, herself a distinguished physiologist, a son who was elected to a Grocer's Company research fellowship in zoology at New College this year, and three daughters.

Dr. Creed went up to Trinity College, Oxford, in 1916 and, after service with the Royal Field Artillery in France and Belgium during the next two years, returned to take a first-class degree in the Honours School of Natural Science (Physiology) in 1921, winning a senior demyship at Magdalen and the Gotch Memorial Prize. He took his clinical training at St. Thomas's Hospital and gained the B.M., B.Ch. and Conjoint qualifications in 1923. He was elected to a fellowship at New College at the age of 27, and served the College for many years as steward, pre-

centor, editor of the college record, sub-warden, and as a Fellow of Winchester College. He took the D.M. in 1930 and was awarded the Radcliffe Prize in 1933. Between the two World Wars Dr. Creed was an active Territorial officer; he was called up for service with the Royal Army Medical Corps in 1939 and served overseas in the Middle East and Italy. He returned to Oxford in 1945 and from 1947 until 1960 was chairman of the management committee of the Warneford Hospital. In 1949 he joined the editorial board of the *Journal of Physiology*, at a time of rapid post-war expansion, and was chairman from 1951 until 1956, a position of particular responsibility in maintaining that *Journal's* high standards. He was president of the physiology section of the meeting of the British Association for the Advancement of Science in 1955.

Dr. Creed was a co-author of the *Reflex Activity of the Spinal Cord*, a physiological classic published in 1932 with Denny-Brown, Eccles, Liddell and Sherrington. He made a number of contributions to the analysis of inhibitory reflexes, and also to investigations of the latency of after-images and of the electro-retinogram with Ragnar Granit. He was particularly interested in the mechanism of hearing and the function of the vestibular apparatus. However, above all, he was a College tutor in the classic tradition who would listen to an essay without interruption, and then, by a few deft and disconcerting questions, demonstrate the value of succinct expression and critical evaluation. Many generations of New College medical undergraduates have owed him a lasting debt for his perceptive and friendly guidance. G. S. DAWES

Mr. Lauge Koch

THE Danish geologist Lauge Koch, who died on June 7 aged seventy-two, was a legendary figure among Arctic geologists (themselves noted for strong characters). His first geological expedition was in 1913; then he was back in Greenland in 1916 with the veteran explorer Knud Rasmussen with the Thule Expedition which was marooned in north-west Greenland until after the First World War ended. Despite the hardships of this expedition (on one journey they ate their starving dogs and a member died) he returned to the same district to lead his own expedition. I met him a good many years later when I joined his party in Scoresby Sound in 1926–27. He had undertaken all the work of planning, stocking the party for the year and choosing the men—the Danish geologist Rosenkrantz, two Eskimo hunters and myself as a specialist on fossil plants. It was Koch who made the long sledge journey in late winter; he left to us shorter journeys and detailed work.

Koch was a big strong fellow, happier on a dog sledge than anywhere else. His character had much strength and half-a-dozen bad sides of which he was cheerfully aware and which all could see; but for me it was saved by his robust and often generous sense of humour. Very likely, too, the partial language barrier made relations easier. I am sure men will long brighten the Greenland night by anecdotes of Lauge Koch, stories that may or may not be true, just as Koch's own stories were. So he would have wished it to be.

Koch continued to lead expeditions for many years. As he grew old he managed to avoid the most exacting physical exertions, but he remained very much the leader. He wanted to complete the picture of the geology of Greenland, and, while he tolerated detail by other hands, his part was to be painted with bold strokes. I doubt if he ever spent months working on one rock formation to perfect knowledge that was already fairly good.

It was natural that he should undertake the work of writing a comprehensive account of the geology of Greenland. Nevertheless, he was the wrong man to do this. Though he had done more than anyone else, his boldness with theory bordered on rashness; it is said he had not the patience to confirm facts, and, worse, that he failed to attribute to others what was due to them. I do not know the truth, but he had already antagonized many (a thing that troubled him not at all) and there was a published counter-blast, a libel action and a hideous row which split Danish geology for years.

No more pioneering work like Koch's remains to be done, and now an aeroplane can do in an hour what a dog sledge took a month to do. But when the next comprehensive work on the geology of Greenland is written I am sure that by far the longest list of entries will be under Koch's name. TOM M. HARRIS

NEWS and VIEWS

Research and Development, U.S. Coast and Geodetic Survey : Dr. John S. Rinehart

DR. JOHN S. RINEHART, former director of the Mining Research Laboratory, Colorado School of Mines, has been appointed to direct the Office of Research and Development of the U.S. Department of Commerce Coast and Geodetic Survey. He succeeds Dr. Christopher E. Barthel, jun., who left the Survey to become executive director of the Kansas Research Foundation at Topeka. As assistant director for research and development, Dr. Rinehart will be concerned with the expansion of the Survey's scientific responsibilities, especially in satellite technology, mineralogy, instrument development, metallurgy, astronomy, ballistics, and physics. Prior to the Second World War, he taught physics at Fort Hayes, Kansas State College, and at Wayne University, and during the War he was executive secretary of Division 4 of the National Defense Research Committee, which directed development of radio and photoelectric proximity fuses. Dr. Rinehart also directed a programme of ordnance research and development at the New Mexico School of Mines. Later, at the U.S. Naval Ordnance Test Station, China Lake, California, he carried out research on problems associated with fracture and deformation of materials subjected to high-speed impact and explosive forces. During 1954–55, Dr. Rinehart carried out research in the University of Cambridge. In July 1955 he joined the Smithsonian Astrophysical Observatory as its assistant director, where he participated in the satellite tracking programme; he was also a research associate in astronomy at Harvard University, where he was concerned with meteorite research. Dr. Rinehart established the Mining Research Laboratory, Colorado School of Mines, in 1958. Born in Kirksville, Missouri, Dr. Rinehart went to the Northeast Missouri State Teachers College, where he gained a B.S. degree in education and an A.B. in physics. He obtained his M.S. degree in physics at California Institute of Technology, and his Ph.D. in physics at the State University of Iowa.

Botany at Queen Elizabeth College: Prof. J. Edelman

DR. J. EDELMAN, who has been appointed to the chair of botany in the Department of Biology at Queen Elizabeth College in the University of London, graduated in botany at the Imperial College of Science and Technology in 1948. Already interested in plant biochemistry, he spent two years in Prof. (now Sir) Hans Krebs's Depart-

R338

ment at Sheffield, obtained his Ph.D. there in 1950, and then returned to the Imperial College to join Prof. F. G. Gregory's team in the Research Institute of Plant Physiology. During 1953–54 he held a Rockefeller Foundation research fellowship at Berkeley, where he was closely associated with Prof. W. Z. Hassid. In 1956 he was appointed to the academic staff of Imperial College as reader in plant physiology and, later, as reader in enzymology. Dr. Edelman's research has been concerned mainly with the enzymatic synthesis of polysaccharides, particularly of fructosans, and he has published many papers on various aspects of this problem. Other publications have dealt with some transformations of sucrose, and with dark-fixation of carbon dioxide in *Kalanchoë*. More recently, he has initiated research into the formation of 'induced' enzymes in mature plant tissues, and has shown that plant hormones (auxins) affect the induction. All plant biochemists will be interested in the future development of these investigations.

The Rock Carling Fellowship: Prof. W. V. Mayneord

Prof. W. V. Mayneord, professor emeritus of physics as applied to medicine, University of London, has been elected the third (1964) Rock Carling Fellow by the Nuffield Provincial Hospitals Trust. The fellowship was founded in 1961 as a memorial to the late Sir Ernest Rock Carling, for many years a Governing Trustee and chairman of the Medical Advisory Panel of the Nuffield Provincial Hospitals Trust. Each holder of the fellowship will seek to review in a monograph the state of knowledge and activity in one of the fields in which Sir Ernest had been particularly interested and which is within the purposes of the Trust. The arrangements provide that the monograph will be introduced by a public lecture given at a medical teaching centre in the United Kingdom. The subject of Prof. Mayneord's review is "Radiation and Health", and this will be introduced at a public lecture at the Medical School, University of Birmingham, on November 19. Admission will be by ticket only, for which applications should be made to the Secretary, Nuffield Provincial Hospitals Trust, 3 Prince Albert Road, London, N.W.1.

Botany in the University of Delhi: Prof. P. Maheshwari

A special volume of the *Journal of the Indian Botanical Society* has been issued in honour of Prof. P. Maheshwari on entering his sixtieth year (42A.. Edited by T. S. Sadasivan. Pp. xxxiv + 330. Madras 5: Indian Botanical Society, University Botany Laboratory, 1963. Rs. 32; 50*s*.; 7 dollars). Prof. Maheshwari has been professor and head of the department of botany in the University of Delhi since 1949. He is well known for his work on the morphology and embryology of vascular plants and the *in vitro* culture of reproductive organs. In addition to a complete bibliography of his published works the volume contains 37 invited contributions on mycology and plant pathology, algae, bryophytes, pteridophytes, angiosperm anatomy, morphology and taxonomy, palynology, embryology, cytology, genetics, plant breeding, palæobotany and *in vitro* culture.

India at Mid-passage

The Overseas Development Institute has collected four short papers discussing aspects of India's third Five Year Plan (*India at Midpassage*. London: Overseas Development Institute, Ltd., 1964. 6*s*.). In the first, Mr. W. Clark discusses the progress of the Plan (1961–66), and suggests that it has not received sufficient publicity, nor have the central planners adequately appreciated the immense difficulty of passing on new agricultural techniques to the mass of the populace. Mr. Clark believes that nothing could be more useful than continued private investment in India, but it is essential that the Aid India Consortium should accept responsibility for playing a definite part in the planned attack on poverty or in the plan for economic growth. The success or failure of India's planned effort to end its poverty hangs in the balance, and although the outcome rests in Indian hands the key factor of external assistance can be applied effectively or ineffectively. There is at present great danger that too little aid will be given just too ineffectively. It is therefore essential that the donors should accept in principle the aims and methods of the Indian Plan and judge the amount that is to be made available in terms of what is needed to achieve its objectives. In the second paper, Mr. R. Neild examines population policy in the context of long-term economic planning in India. He points out that any population policy is unlikely to do more than moderate the growth of the population over the next 10 or 20 years, and stresses the urgent need to expand programmes of family planning as fast as possible and to survey the results obtained so far. There is also the broader question of the priority and attention which should be given to population policy and economic planning. He concludes firmly that if the objective of Indian planning is to raise the living standards, far too little is now spent on population policy. E. F. Schumacher examines the problem of rural industries, including the need for a suitable technology and also for a suitable form of organization. He suggests that detailed design investigations should be undertaken on all industries envisaged for establishment in rural areas. K. B. Lall discusses Indo–British trade prospects.

Expansion of Higher Education in Britain

In a brief debate in the House of Commons on July 29 on scientific and technological education, opened by Dr. J. Bray, Sir Edward Boyle, the Minister of State for Education and Science, reaffirmed the Government's endorsement of the recommendations of the Robbins Report regarding the building-up of technological universities and the development of management studies. He thought that the Robbins figure of 45,000 full-time advanced students in technical schools other than the Colleges of Advanced Technology was an underestimate of what would be achieved, and insisted that the Government would plan firmly on the basis of 219,000 students in institutions of university status by 1973–74, and 390,000 full-time places in higher education in the full ten-year plan. Output of qualified scientists and technologists this year was estimated as 19,500, and in the present year 1,073 awards of Dip.Tech. had been made. Between 1953 and 1968 capital work to the value of £18·5 million would have been done at the Imperial College of Science and Technology and its numbers would have increased from 1,700 to 3,700. Between 1955 and 1967 the capital expenditure of the Manchester College of Science and Technology would exceed £6·5 million with an increase in numbers from 800 to 2,700, while the University of Strathclyde over the same twelve years would have had a capital outlay of £5·25 million. Between 1955 and 1966, capital allocations to the University of Durham would total about £5·75 million, of which a little less than £1 million would be for applied science; while in the same period capital allocations to the University of Newcastle upon Tyne would total £9 million, of which £3·7 million would be for engineering and applied science. Sir Edward Boyle also paid tribute to the contribution of the Sunderland and Rutherford Technical Colleges and of the Constantine College at Middlesbrough to the provision of higher technical education in the North-East.

Financing Education in Britain

A pamphlet recently issued by the National Union of Teachers looks at the system of educational finance in Britain (*The Financing of Education: A Discussion Document*. Pp. i + 38. London: National Union of Teachers, 1964. 2*s*.). It examines suggestions that have

been put forward for changes and modifications in the present system, or for its retention in its existing form in order to see whether it can be made to work or whether some new and better system can be found. The ways in which different sectors of the system are financed are reviewed together with the controls which have been used to deal with increasing expenditure on education (estimated in 1961–62 at £898 million for present expenditure and £163 million for capital expenditure, or 4·4 per cent of the gross national product). Some important points are suggested for consideration by the local and county associations of the National Union of Teachers. Emphasis is placed on the belief in the unity of education which runs through all the thinking of the Union, and on the recognition that in some fields it is the duty and right of individual teachers or groups of teachers to determine what is best in any particular circumstances. It is regarded as the right and duty of the Union to defend this freedom of professional judgment. Here the pamphlet suggests that, if the present grant system continues, there will, in effect, be a breakdown in local Government finance, at least as applied to education. Possible alternatives to the present grant system are: the devising of new techniques of rate assessment and levying that would mitigate the impact and social injustices of the present system; alternative or additional methods of raising local revenues; the reorganization of local education authorities into regional or larger or *ad hoc* authorities. The associations should also consider whether the Union should support a return to a system of specific grants; the transfer of payment of teachers' salaries to the Central Exchequer; the financing of different parts of the education system by different methods; a nationally financed system of education. Appended to the pamphlet are summaries of the main points made by Mr. J. R. Sampson, Mr. N. Morris, Mr. John Vaizey, Dr. Horace King, M.P., and Sir William Alexander before the Union's panel on educational finance.

Sociology in Professional Training

THE question of what should be included in a sociology syllabus is frequently raised and many who are responsible for introducing the subject have indicated that they would welcome advice on this matter. The appropriate syllabuses could, with obvious advantage, be drawn up as a result of consultations between members of the various professions and sociologists who specialize in particular branches of the discipline. For example, discussions could be held between training college principals and educational sociologists, town planning officers and urban sociologists, those concerned with management studies and industrial sociologists. With the view of improving sociology syllabuses in general the British Sociological Association has established a panel of members from various fields in sociology to discuss the needs of professional organizations and to give advice in formulating sociology syllabuses. Further information can be obtained from the Honorary General Secretary, British Sociological Association, Skepper House, 13 Endsleigh Street, London, W.C.1.

Family Planning Association

THE 33rd annual report of the Family Planning Association describes the success of the campaign to secure a large sum of money to extend the Association's activities overseas. Over the past four years the number of Family Planning Association clinics in Britain has increased from 300 to 409, oral contraceptives have been introduced as a normal method of birth control, training for lay workers has developed, training for doctors and nurses has been improved, advisory visits to clinics have been initiated and the procedure for the inspection of training clinics overhauled. A limited cancer smear service is now available, clergy courses are regularly arranged and relations with a number of universities are much closer. There were 409 clinics in 1963, compared with 392 a year earlier. During the year covered by the report more than 335,000 individual patients were seen, 13,670 of whom used oral contraceptives; 138 of the Association's clinics undertake cervical smear examination, an important contribution towards the early detection of cancer of the cervix.

Abnormalities of the Sex-Chromosome Complement in Man

KNOWLEDGE of human chromosome anomalies as causes of abnormal somatic and sexual development is relatively new, and is increasing rapidly on account of the technical advances that have been made. However, techniques are still time-consuming, and laboratories that specialize in this work can cope with only relatively small numbers of patients while, in general, fairly large numbers are required to obtain statistically sound information on a number of points concerning the types, origins and outcomes of human chromosome anomalies. Therefore, the publication of detailed reports by those laboratories which are able to make an efficient and accurate examination of persons with potential chromosomal anomalies is particularly welcome. In *Abnormalities of the Sex-Chromosome Complement in Man*, Dr. W. M. Court Brown and his colleagues have given as much valuable information about each case as they have been able to assemble during their painstaking work. (Privy Council—Medical Research Council Special Report Series, No. 305. Pp. viii+239+3 plates. London: H.M.S.O., 1964. 27*s*. 6*d*.)

The data have been collected in connexion with the Registry of Abnormal Human Karyotypes set up in 1959 in the Medical Research Council Effects of Radiation Research Unit in Edinburgh. The primary object of the Registry is to enable an investigation to be made of the long-term effects of the chromosomal abnormalities that have been detected in man. This report deals with 266 subjects with anomalies and discrepancies of the sex chromosomes—the total number of cases with sex-chromosome defects which have been registered from 1959 to the end of 1962. There are two introductory parts: in the first are described the techniques and methods of examination of human sex-chromosome abnormalities by means of sex-chromatin and metaphase-chromosome investigation, and a section is devoted to the recognition of sex-chromosome mosaicism; in the second part, the literature concerning chromosomal findings in the persons described in the main body of the report, which follows, is briefly and critically reviewed. The third and main part deals with the persons reported to the Registry; reasons for referral, history and general clinical findings are given and reference is made to publications in which the patient has previously been reported. The persons examined are grouped into three main sub-sections according to phenotype; 134 have a male phenotype, 128 are phenotypically female and 5 are true hermaphrodites. 99 of the 134 phenotypic males have an XXY sex-chromosome complement and 24 have sex-chromosome mosaicism. Of the 128 phenotypic females, 38 are XO, 22 are sex-chromosome mosaics, 33 are XXX and 26 (not 20 as stated on p. 129) have an XY complement, and of these, 20 are examples of testicular feminization. The report contains a great deal of factual information on practically all types of sex-chromosome anomaly discovered in man, and it is to be hoped that new material will be published in similar form as it becomes available from time to time.

Total Beta Activity in Global Fall-out in Australia during 1963

CONTINUOUS sampling of fall-out for the measurement of total β-activity was maintained through 1963 by the

Atomic Weapons Tests Safety Committee in an Australia-wide network of sampling stations. Daily sampling was carried out at 24 stations for the first five months of the year, after which the number of stations was reduced to 11. Monthly sampling, using two methods, was conducted at eight stations throughout the year. A report by R. J. I. Alsop, W. J. Gibbs, J. R. Moroney, D. J. Stevens and Prof. E. W. Titterton presents results for total β-activity measurement on all these samples (*Aust. J. Science*, 26; May 1964). The measurements were intended to provide information on tropospheric and early stratospheric fall-out over Australia from high-yield nuclear weapon tests in the atmosphere, carried out by the U.S.S.R. and the United States during 1961 and 1962. The most recent release of fission products into the atmosphere in sufficient quantity to be of significance in considerations of global fall-out occurred in late December 1962. Results reported complement data obtained by the Committee in its extensive and continuing survey of strontium-90 in the Australian environment. All stations exposed 6 in. × 12 in. gummed films continuously for the purpose of providing daily samples for the measurement of total activity. The gummed films were changed every 24 h; the radioactivity measurements were made at a central laboratory. Up to May 31, daily gummed film sampling was carried out at 24 stations. Only 22 of the 3,624 daily samples taken during this period showed activities above the minimum detectable level; even the higher activities were just above the minimum detectable level. The survey showed that levels of total β-activity in fall-out over Australia throughout 1963, as monitored by the daily and monthly sampling methods, were notably lower than in 1962. Towards the end of 1963 the total activity-levels were approaching those recorded before the resumption of nuclear weapon testing in 1961. However, nuclear weapon testing during 1961 and 1962 resulted in the injection of substantial quantities of strontium-90 and cæsium-137 into the stratosphere which will contribute to the low levels of these long-lived fission products expected in fall-out over Australia. There were indications during 1962 that some strontium-90 in fall-out over Australia at that time was arising from recent nuclear weapon testing. Efforts in the fall-out monitoring programme will now be devoted to the continuing assessment of the levels of these long-lived fission products in the Australian environment.

British Lichen Distribution Maps

The British Lichen Society now has a Distribution Maps Scheme to record the distribution of lichens within the British Isles. The Scheme is based on the 10-km square system of the National Grid. A record card listing 154 easily identified lichens, with one side blank for additions, is available for use in the field. Eleven members are mapping individual genera or species for early publication. A large number of species are confined to the Highland Zone of Britain, and many lichens have restricted distributions due to such factors as climate, soil conditions, forest clearance, survival of open communities, atmospheric pollution, etc. Maps showing the precise British distribution of lichens will therefore be of considerable interest, and will help to disentangle the various factors which affect the distribution of particular species. Full details of the Scheme can be obtained from the Society's mapping recorder, Mr. M. R. D. Seaward, Lynwode, Vicarage Avenue, Wrawby, Brigg, Lincolnshire. Details of the British Lichen Society itself can be obtained from the secretary, Mr. J. R. Laundon, Department of Botany, British Museum (Natural History), Cromwell Road, London, S.W.7.

Textile Research in Poland

The Politechnika Łódźka has published a further issue of its Scientific Bulletins, details of which were given earlier (*Nature*, 201, 1171; 1964). Issue No. 11 (1964) of *Włókiennictwo* contains contributions from the Department of Mathematics of the Chemical Faculty on statistical analysis, and from the Department of Textile Raw Materials and Metrology on the effects of changes in structure, caused by heat-setting, on the mechanical properties of polyethylene terephthalate fibres during stretching. There are also articles on the causes of irregularity in carded flax sliver, and on the analysis of cotton combing in relation to fibre length distribution.

Wellcome Trust Grant for Neurophysiological Research in Canada

A grant of £10,000 is to be made by the Wellcome Trust in London to Dr. V. C. Abrahams and Dr. E. P. Langworth, Queen's University, Kingston, Ontario. This will enable them to establish the necessary computer and tape system for their research work on the neurophysiology of the brain stem. Dr. Abrahams and Dr. Langworth, both of whom formerly worked at the National Institute of Medical Research, Mill Hill, London, went to Queen's University, in 1963, to establish a Neurophysiological Research Unit. Together they have drawn up plans for joint research with other university departments in a programme of research on communication theory, particularly on organization in the brain stem.

Carlsberg–Wellcome Travelling Research Fellowships

The Carlsberg Foundation of Copenhagen and the Wellcome Trust of London have announced that the Carlsberg–Wellcome travelling research fellowships for the year 1964–65 have been awarded to Mr. Jens Hyldgaard-Jensen, of the University of Copenhagen, and Mr. G. C. Coles, of the University of Cambridge. Mr. Hyldgaard-Jensen, recently a research scholar at the Royal Veterinary and Agricultural College, Copenhagen, will work at the Rowett Research Institute, Aberdeen, under the guidance of Dr. R. N. B. Kay, on problems of the physiology of feeding in cattle. Mr. G. C. Coles, a post-graduate student in the Department of Zoology at the University of Cambridge, will carry out research under Prof. T. Weis-Fogh at the Zoophysiological Laboratory at the University of Copenhagen.

Announcements

Prof. F. C. Steward, professor of botany in Cornell University, Ithaca, has been awarded the Stephen Hales Prize of the American Society of Plant Physiologists, for his distinguished work on the salt uptake of plants, the nitrogenous constituents of plant tissues, and plant growth regulators.

A joint meeting of the Challenger Society and representatives from the Marine Laboratories (Development Commissioners' Scheme) will be held at the Freshwater Fisheries Laboratory, Pitlochry, during October 14–15. Further information can be obtained from the Secretary, Challenger Society, National Institute of Oceanography, Wormley, Godalming, Surrey.

A symposium on "Concrete Quality", organized by the Cement and Concrete Association, will be held in London during November 10–12. Further information can be obtained from Dr. R. P. Andrew, Cement and Concrete Association, Wexham Springs, Slough, Bucks.

An international conference on "General Relativity and Gravitation" will be held in London at the beginning of July 1965. The main meetings will be held during July 1–10, but arrangements will be made so that those participants who wish may arrive from June 28 onwards in order to take part in discussions and informal seminars. Further information can be obtained from the chairman of the local organizing committee, Prof. H. Bondi, Department of Mathematics, King's College, Strand, London, W.C.2.

THE GLASGOW UNIVERSITY EXPLORATION SOCIETY EXPEDITION TO MINGULAY

By J. F. ROBERTSON, J. B. RANKIN and DR. D. R. BOWES
University of Glasgow

AND

A. M. HOPGOOD
University of St. Andrews

A GLASGOW University Exploration Society expedition to the uninhabited Island of Mingulay (Nat. Grid NL 056783), some twelve miles south of Barra in the Outer Hebrides, was made during June 21–July 14, under the leadership of Mr. J. F. Robertson. The Island is essentially made up of rocks of the Lewisian complex[1] and the geological investigations, undertaken by six of the expedition members under the direction of Dr. D. R. Bowes and Mr. A. M. Hopgood, are a continuation of Lewisian investigations being carried out in the Departments of Geology of the University of Glasgow and the University of St. Andrews. Topographically the dominant features of the island are the sheer cliffs, some more than 700 ft. high, on the western seaboard, and a large, sheltered eastward-facing glacially-carved amphitheatre which rises from a sandy bay on the eastern seaboard. A crofting settlement, almost completely abandoned in 1909, is situated in the lower parts of this amphitheatre largely on superficial deposits of boulder clay and sand. This 'fossilized' settlement, which has remained well preserved by virtue of its isolation, was investigated under the direction of Mr. J. F. Robertson and Mr. J. B. Rankin as part of the crofting investigations being carried out by the Departments of Geography and Archæology of the University of Glasgow.

The Lewisian rocks are dominantly banded gneisses of intermediate to acid composition. They show evidence of metamorphic reconstitution at hornblende granulite facies, and subsequent retrogressive effects, and are injected by many structurally controlled pegmatite veins. The effects of at least five periods of folding and associated deformation are displayed. In addition there is evidence of two periods of pseudotachylite development, one within the Lewisian sequence and the other associated with the Hebridean Thrust. In summary the geological sequence of events is:

(1) The formation of the prominent banding, associated with tight isoclinal folding of lithological layers, tectonic disruption and metamorphic reconstitution at hornblende granulite facies. Strong linear and planar elements developed with mineral growth axial plane to the fold structures. The first prominent elements of rock microfabric were formed at this stage.

(2) The development of asymmetrical folds which fold the banding. The fold axes plunge gently north while the axial planes trend approximately north-west–south-east and dip in a north-easterly direction at a moderately steep angle. The dip of the north-eastern limb is consistently much less than that of the south-western limb which is commonly near vertical or overturned. A secondary foliation is developed parallel to the axial plane. The largest folds observed are of this type and they control the gross attitude of the banding. Quartzofelspathic pegmatitic material developed and its uprise was controlled by the axial planes of these folds.

(3) Pseudotachylite was formed and injects gneisses and pegmatites. Bands of pseudotachylite breccia trend east-north-east–west-south-west and dip toward the south-south-east at approximately 30°.

(4) Open folding with much small-scale crenulation and the development of axial plane cleavage. Fold axes plunge gently towards the south-east and axial planes dip at a moderately steep angle to the south-west.

(5) Folding of variable intensity on approximately east–west trending axes which plunge gently eastwards. Interference structures resulting from the effects of these folds on the asymmetrical folds are common and much of the variation in attitude of the lithological layering is the result of this interference. The most common and the largest pegmatitic veins trend east–west and are emplaced parallel to the axial planes of these folds.

(6) Variable, very open folding with near horizontal axes generally trending between north-north-east and east-north-east.

(7) Thrusting, dislocation and pseudotachylite formation associated with the development of the Hebridean Thrust.

(8) Emplacement of dolerite dykes (of presumed Tertiary age).

Events 1–6 are considered to represent the Lewisian history of the rocks and they correspond, both individually and in sequence, with Lewisian events shown by the rocks of Barra investigated by one of us (A. M. H.). There is also considerable similarity to the Lewisian rocks of the mainland, particularly in the vicinity of Gairloch, investigated by one of us (D. R. B.), but correlation at this stage, in the absence of absolute age dates, is considered premature.

The main settlement, which was surveyed by plane table at a scale of 1 : 500, consisted of approximately thirty crofts. It was located on the seaward side of the main track joining the school and St. Columba's Chapel, both of which were set apart from the rest of the village. The quality of the dry stone masonry of the croft houses was generally good, entire walls being intact in some cases, some with stones up to three-quarters of a ton. All the croft houses were roofless and most were approximately 30 ft. long, 15 ft. wide and 5 ft. high (internal measurements) with doorways 4 ft. 6 in. high by 2 ft. 6 in. wide. Both doorways and windows were topped by stone lintels. The walls, which consisted of inner and outer stone shells with rubble between, were approximately 4 ft. thick and generally rounded at the corners. Most of the croft houses had a fireplace and chimney in the end wall, and, with the exception of two that were gabled, the houses were hip-ended. The chief area of crofting land, surveyed at a scale of 1 : 2,500, was located on the landward side of the main track on the southern flanks of the amphitheatre. Elongate rectangular croft strips extended down the well-drained slopes from the Lewisian outcrops to one of the small streams cut in the boulder clay. Drystone dykes, some in very good condition, bounded the strips of land—good quality pasture broken by rock outcrops towards the head-dyke. The remains of the smaller crofting settlement at Skipsdale, in the south-eastern part of the island, were also investigated.

The expedition could not have been arranged without the generous financial assistance of the University Court of the University of Glasgow, the Carnegie Trust for the Universities of Scotland and the Royal Scottish Geographical Society. Grateful acknowledgment of assistance is also made to Kodak, Ltd., Hanimex (U.K.), Ltd., the Northern Lighthouse Board, the keepers of Barra Head Lighthouse, the Inverness Education Committee, our many kind friends in Castlebay, Barra, and Prof. Ronald Miller, Dr. J. B. Caird and Mr. G. Petrie of the Department of Geography, and Dr. H. Fairhurst of the Department of Archæology, University of Glasgow.

DEVELOPMENT OF NORTHERN AUSTRALIA

In his presidential address to the Section of Geography and Oceanography at the thirty-seventh annual congress of the Australian and New Zealand Association for the Advancement of Science, Prof. R. H. Greenwood (University of Queensland) analysed the conditions for accelerated development in Northern Australia (*Australian Journal of Science*, 26; April 1964).

The first point which he emphasized was the necessity for an enlarged market for Australian goods. Since the largest domestic market is in the south-east, and, since Australian transport costs are high, there is no purpose in seeking to replace existing production in the north. Additional markets may be created in four sectors —two domestic and two foreign. The domestic market is being constantly enlarged to keep in line with the increasing Australian population; however, it could—with benefit to the economy—be increased still more by replacing imports by home-produced goods. The latter offers the more appealing prospects, but in the main it depends on the ability to pioneer new techniques for the production of tropical crops that are normally labour-intensive (rubber, coffee, tea, copra, etc.) and to intensify the search for minerals and oil (which constitutes a particularly large item on the import bill). Overseas markets can be expanded either by seeking new buyers for the conventional products of the north (mainly beef, sugar and minerals), or by innovations such as exploiting newly discovered minerals, or by the large-scale production of tropical grains and other food crops and raw materials for Asian markets. In theory, there is a substantial potential in each of these market sectors. The major problem is high costs, and this is of such significance to the basic proposition that the second condition for accelerated development is the ability to reduce overall production costs, or (and this is not by any means the same thing) to reduce the price charged for goods produced in the north.

There are some ways in which small savings can be made. It would be an advantage to increase productivity in those parts of the Australian Commonwealth that are nearest to her customers. It is unsatisfactory that Australia should, in a geographical sense, face away from her customers. It is a significantly shorter haul from Darwin to Hong Kong, Madras or London than it is from Melbourne, and the shorter time of the sea voyage may be important for technical reasons as well as cost (for example, in the ability to deliver chilled beef to the United Kingdom). Land would be comparatively cheap and every advantage of large-scale commercial production could be reaped in agriculture. The largest element in the higher cost margin, however, relates to the establishment of essential services—water, power, transport and building —in areas remote from the main centres of production. The capital costs involved in setting the productive machine in motion are high and the benefits derived would be long-period, rather than short-period, benefits of a kind which reduce the attractiveness of the proposition to private enterprise. Moreover, public funds available for such capital developments are not unlimited.

This leads to the third condition for development. The benefits of capital investment in the north must be maximized. It would be essential to extract the utmost value from each project. In an area as big as tropical Australia, there is likely to be a measure of regional dispersal of public expenditure, each item adding different amenities in widely separated districts. The main item of public investment in the north should, however, be carefully planned to provide as many of the prerequisites for diversified development as possible. An ideal model would be the provision of a water storage that could be used both for irrigation, town supply and power generation to a nearby area with suitable conditions for the cultivation of an industrial crop which could be processed—at least in part locally—with road access to a not-too-distant port. The anticipated benefits would include the capacity of the original investment to bring about growth of ancillary and dependent activities in an exponential manner and, in particular, to stimulate the growth of small urban communities, the increasing needs of which would create opportunities for additional use of local land, water, power and other services. Such a deceptively simple model is not by any means easily created. For example, there is the temptation to start with the selection of a suitable dam-site and see what can be done with its surroundings. Governments in many parts of the world have been prone to build dams first and think of ways of using the water they retain afterwards.

The starting-point should be the selection of a crop with carefully evaluated market prospects. The next stage would be the location of one region in which market surveys indicate that the production of the crop is justified on a large scale. This should be a region with maximum nodality, with country capable of complementary rural production in different districts, with maximum access to a port, roads, railways and other services or with optimum means of creating such access. The logistics of geographical location are of immense importance, and the districts around Rockhampton and Darwin have great possibilities as regards the polarization of new developments. They are natural nodes to which easy lines of communication converge and around which varied resource patterns are disposed. They are of particular significance, as notably Australia lacks such naturally endowed nodal districts. Dam sites should only be looked into after the purpose has been satisfactorily defined of the new developmental scheme and the optimum location for its introduction agreed.

A GREAT PATHOLOGIST AND NATURALIST

Adolph Lutz, one of the world's greatest medical zoologists, was born in Rio de Janeiro in 1855*. His parents were Swiss, and when they returned to Berne in 1865, Adolph was educated in Switzerland. When his parents later returned to Brazil, Adolph was left behind to go to school in Basle. He had by then already decided to spend his life studying natural history, and in 1874 he began to study medicine at the University of Berne, taking courses also at Leipzig, Strasbourg and Prague, and studying biology as well. In 1879 he received his licence to practise medicine. Already he had published papers on the Cladocera of the neighbourhood of Berne and Leipzig. He went to Vienna and Paris for post-graduate studies, and then returned to Brazil, where he practised medicine from 1882 until 1892 in the province

* *Adolpho Lutz* (1855–1955): *Vida e Obra do Grande Cientista Brasileiro*. Pp. 55. (Rio de Janeiro: "Comissao do Centenario de Adolpho Lutz", Conselho Nacional de Pesquisas.)

of São Paulo and elsewhere. In 1885 and 1886 he went to Hamburg to study dermatology. In 1887 he moved to the city of São Paulo until the pandemic of yellow fever in Campinas in 1889, and he was later summoned to Hawaii to investigate leprosy. Although he was busy as a country doctor, Lutz found time to publish papers on helminthology and medicine, among which was a monograph on *Ankylostoma duodenale* and ankylostomiasis, and others on ascariasis and the mode of infection with the tapeworm *Taenia*. On the latter subject he experimented on himself. In 1886 he published a paper on the structure of the organism that causes leprosy, proposing to include it in a new genus called *Coccothrix*, including the causal organism of tuberculosis in the same family, but the name *Coccothrix* was not adopted, although the relationship of the two organisms is nowadays recognized. In 1885 he discovered a new disease of children, now known as pink disease, and he published further papers on leprosy, based on his observations made in Brazil. Working in Honolulu he published papers on dermatology, and in 1891 a paper in which he separated amoebic from bacillary dysentery.

In Honolulu he met and married an Englishwoman, Amy Fowler, who had gone there as a volunteer nurse. After a spell in San Francisco, he and his wife returned to Brazil in 1893, where two children were born to them. In the same year Lutz was appointed vice-director of the new Bacteriological Institute of the State of São Paulo, founded by Felix Le Dantec, and later he became its director. Here he did much work on yellow fever, malaria and typhoid fever, making possible the accurate diagnosis of these endemic diseases, and directing campaigns against them. Hearing that the transmission of yellow fever by mosquitoes had been proved, Lutz, together with his colleague Ribas, director of the State sanitary service, instituted, in spite of much opposition, measures against the mosquitoes. He also worked at this time (1899–1906) on cerebrospinal meningitis, plague and myiasis, and published papers on them. In 1897–98 he discovered the sylvan form of yellow fever in the area between São Paulo and Santos, and rightly ascribed the transmission of this to the forest mosquitoes rather than to *Aëdes aegypti* (*Stegomyia fasciata*).

In 1907–08 he discovered and described two new diseases caused by fungi, namely, a sporotrichosis of man and rats, and the disease later known as the mycosis of Lutz. From 1903 onwards Lutz began to work on medical entomology, publishing papers on the technique of the study of mosquitoes, on bloodsucking Diptera and on new species of Culicidae and Tabanidae.

He also did pioneer work on veterinary medicine in Brazil, investigating among other diseases equine trypanosomiasis. Later he was asked to join the staff of the Instituto Oswaldo Cruz, becoming chief of the Division of Medical Zoology. This post gave him time for work on medical entomology and helminthology, and for work on snakes and amphibia. He also wrote papers on Tabanidae and a monograph on the Simuliidae, parasitic Hippoboscidae and the forest flies and Ceratopogonidae, contributing chapters on insects of medical importance to the *Handbuch der pathogenen Organismen*.

From 1916 onwards he returned to work on helminthology, doing pioneer work on schistosomiasis in Brazil, studying the biology and ecology of the intermediate hosts involved. Later papers were on trematodes and scorpions in connexion with his lectures on poisonous animals. His earlier interest in leprosy was retained to the end of his life, and increasingly he regarded it as a disease transmitted by mosquitoes. Lutz travelled widely in Brazil in the course of his studies, and in 1928 he warned the country of the danger of outbreaks of malaria when *Anopheles gambiae* was carried from Africa to South America. It later caused, in north-eastern Brazil, one of the most disastrous outbreaks in the history of the disease.

In the course of his life Lutz named many insects, worms, molluscs and frogs, and many species were named in his honour. He was an honorary and corresponding member of many learned societies, and received many honours. On the first centenary of his birth the Brazilian Government issued a stamp with his portrait on it, and several towns in the State of São Paulo, where he did much beneficent work, named streets after him. His research extended over 61 years, and a complete edition of his publications, of which there are more than two hundred, is being planned.

G. LAPAGE

ROTHAMSTED EXPERIMENTS

IN 1919, Sir Alfred Hall wrote that the purpose of the Rothamsted Experiments was "to ascertain the conditions under which the plant grows and the soil supplies it with nutrient". Since then agricultural research has developed in many spheres, and it is clear from the annual report of the Rothamsted Experimental Station for 1963 * that at present the classical investigations, initiated by Lawes and Gilbert over one hundred and twenty years ago, form only a part of the manifold activities of the Station.

The report follows the same pattern as in previous years, consisting of reports from twelve research departments, the farms at Rothamsted and Woburn, Broom's Barn and Woburn Experimental Stations, and a summary of the work of the Soil Survey for England and Wales. In an admirable general report, the director, Mr. F. C. Bawden, has commented on a few of the subjects of research carried out, but emphasizes that his introduction is merely an indication of the range of work of the Station, and is in no way a summary. Similarly, in a short review it is possible to mention only a few of the items contained in the report, and I can only hope that the interested reader will explore the report further for himself.

Some of the most interesting and important scientific developments have come from the research of the Departments of Physics and Botany into the phenomena involved in crop physiology. Detailed investigations into the physical conditions within crops and the growth of species under different sets of conditions have been carried out to obtain information about the factors which limit the productivity of healthy crops receiving adequate water and nutrients. As the director pointed out, until such knowledge is available it will be impossible to say with certainty whether a variety is producing its maximum yield, or what conditions increase yielding capacity. The Physics Department has been concerned with the energy involved in photosynthesis, and carbon dioxide flux measurements. Already several important trends have emerged, and some earlier ideas have had to be modified. For example, the soil's contribution to carbon dioxide uptake is much less than had been thought. Evapo-transpiration studies have been continued, in particular the estimation of insolation from cloudiness records, and the calculation of net radiation from measured solar radiation, analysis of evaporation and records of heat balance. The value of these evapotranspiration measurements as a basis for assessing irrigation needs should be fully realized when the new irrigation scheme is installed at Rothamsted. In the Botany Department, controlled environment rooms have been used to examine the effects of varying temperature and humidity on plant growth. Apart from the controlled

*Lawes Agricultural Trust. Report of the Rothamsted Experimental Station for 1963. (Harpenden: Rothamsted Experimental Station, 1964.) 15s.

environment studies, other aspects of crop physiology, such as photosynthesis of ears of cereals, and dependence of the grain : leaf ratio on radiation, have been studied. These physiology studies, in conjunction with the work of the Physics Department, should yield fundamental information of far-reaching practical consequence.

In a year in which much has been written and spoken about the harmful effects of pesticides on Nature, it is gratifying to record that several departments have devoted considerable time and effort to pesticide evaluation. Although the investigations are of widely varying character, they have all been carried out with a common purpose—"to increase the efficacy of pesticides while decreasing the risk of unwanted side-effects". The Insecticides and Fungicides Department has been concerned with the search for effective new substitutes for the more persistent organic chlorine compounds and has experimented with organo-phosphorus compounds. Initial experiments have shown that yields of wheat in a wireworm-infested field were considerably increased by applying some of these latter compounds, but further work is required to determine whether their application is a commercial proposition. In the Entomology Department, the experiment on the long-term effect of DDT and aldrin has been continued. The extent to which insecticides such as aldrin, dieldrin and DDT accumulate in worms and other soil invertebrates is being studied. Results so far indicate that the concentration of dieldrin in earthworms is several times greater than in the soil itself. Another important aspect of these investigations is the re-colonization of sterilized soil by soil invertebrates which help to maintain soil fertility.

In agricultural entomology, although much time and effort has been spent in studying pests themselves, comparatively little work has been done on their relations with the growing plant, especially on the way in which pest populations of different sizes affect the growth and yield of plants at different stages in their development. Such an investigation has been commenced at Rothamsted on both root and seed crops.

The Biochemistry Department is pursuing its interest in the extraction of leaf protein as a contribution to the improvement of protein supplies in the underdeveloped countries. Three protein-extraction units have been set up in Lincolnshire, Lucknow and Jamaica, and a pulping machine has been sent to Makerere for an investigation into the prospects of using leaf protein in Uganda. The factors which control the suitability of a crop for leaf-protein extraction are the amount of protein which accumulates in the leaf and the readiness with which it can be extracted. Maize has been found to be particularly useful, as good extraction rates are obtained over a substantial part of the growing period, thus allowing continuity of production throughout the summer and autumn.

In the Chemistry Department, work on organic manures, soil structure and nutrient uptake has been continued. Attempts have been made to relate laboratory measurements of easily soluble nutrients to nutrient uptake in the field. Variations in such correlations in the past have been caused by variation in the structure of the same soil in different years. Ways of altering the soil structure have been tried in order to distinguish between the nutrient and physical effects of organic manures. Experiments carried out to investigate the way in which root growth and crop nutrition are influenced by soil structure have confirmed the theory that it is the rigidity of pore spaces in the soil rather than their size or continuity which affects root growth. Fertilizer placement experiments and work on nitrogen fertilizers, particularly ways of lessening losses of nitrate by leaching and denitrification, should prove to be of considerable practical significance.

The lay-out of the report, whereby the work of each department is recorded separately, often makes it difficult to deduce how much collaboration there has been between departments. The Plant Pathology report, however, includes an outstanding example of such collaboration, in the work on the cause of farmer's lung disease, which involved the Departments of Soil Microbiology, Plant Pathology and Biochemistry, and the Institute of Diseases of the Chest. Many of the problems in agriculture can only be tackled by interdepartmental co-operation, and it is hoped that the extent of such co-operation might be more clearly indicated in future.

The report contains two special reviews, on mobilization phenomena in soils and on the classic Park Grass Experiment. The character of these two reviews reflects the satisfactory blending of applied and pure scientific research conducted at Rothamsted. In his excellent review of mobilization phenomena, C. J. Bloomfield combines a summary of his own well-known work on the movement of iron in soils with a critical survey of the contributions of other workers in this field. Among the many important points he raises are the need to record the presence or absence of sulphate in investigations of the chemistry of waterlogged soils, and the difficulties involved in ferrous iron determinations in soils containing organic matter.

The report ends with a series of abstracts of papers published by the staff over the year. In all, two hundred and forty papers have been written, which is in itself a fair indication of the substantial contribution made by Rothamsted to present-day agricultural research.

D. A. MacLeod

THE ELECTRICAL RESEARCH ASSOCIATION

THE activities of the Electrical Research Association throughout the year 1963 are recorded in the forty-third report presented to the annual general meeting held on April 29*.

Perhaps the most notable development is the building up of a substantial research programme in the electronics field. This work, which is concentrated on thin films, is directed towards helping the manufacturer of thin-film devices first by accumulating information about the production of films, the effects of impurities and the factors determining the suitability of materials for particular applications. By providing information on manufacturing techniques such as methods of deposition and on the effect of different vacuum conditions on the performance of products, and by assistance in the analysis of faults occurring after manufacture, the Association should be able to provide much of the technical background required by industry.

Silicon monoxide, which is widely used for making insulating layers in cryatrons and microcircuits, is being investigated as its dielectric properties are known to be variable and dependent on uncontrolled deposition parameters. The evaporation of films and the investigation of their electrical properties are being carried out using an ultra-high-vacuum system in which the residual gas pressure can be reduced to 10^{-9} torr.

In relation to the deposition of thin metal films, an investigation is proceeding on the production, collimation and control of a beam of metal ions which can be directed at a suitable receiving surface. An arc discharge *in vacuo* between copper electrodes is being used to produce a high density of copper ions. It is thought that this technique will be of importance in the fabrication of thin-film

* The Electrical Research Association, 43rd Annual Report for the year ended 31st December, 1963. Pp. 92. (Leatherhead: The Electrical Research Association, 1964.)

components in which high standards of delineation and rate of deposition are necessary. Investigation of the conductivity of thin metallic films resolves naturally into that of three conduction mechanisms representing three stages in the formation of the film, namely: (1) conduction between discrete aggregates; (2) conduction between aggregates linked by metallic bridges; (3) conduction along a thin homogeneous plane parallel film. Work is in progress on all three conduction mechanisms, the last-named having already been investigated extensively.

A significant part of the Association's work on insulating materials is directed towards establishing or improving British Standards. For example, a proposed specification for capacitor tissue is nearly complete and will shortly be issued to members. A preliminary investigation is in progress on the use of non-polar plastics at a stress of about 500 kV/cm. A knowledge of the long-term effect of these high stresses and of the mechanism of failure in the absence of discharges is essential to the design of high-voltage plastic insulated cables. Theoretical work has continued on fundamental phenomena in dielectrics in the stable state and, in relation to the fundamental phenomena of instability, a paper on the theory of the stability of bubbles in insulating liquids in an electric field has been accepted for publication by the Royal Society.

Research on high-temperature plasmas has comprised further work on the magnetically constricted low-pressure d.c. arc. Probe and microwave techniques together with spectroscopic investigations have confirmed the part played by the cathode fall of potential in the production of the apparent high ion temperatures in excess of 2×10^{6}° K which are observed in the positive column of this low-power arc. This work has prompted a re-examination of existing theories of electrode mechanisms. The effect of electrode boundary layers and the mechanism by which current can be extracted from a flowing ionized gas constitutes one of the least understood problems of magneto-hydrodynamic power generation. A laboratory model of a novel form of plasma furnace has been built for the purpose of spheroidizing highly refractory particles.

Circuit breakers and the phenomena associated with current interruption continue to occupy an important place in the research programme. Particular attention is being directed to the further development of the 'synthetic' testing of circuit breakers. The demand for circuit breakers with still higher rupturing capacities implies increase in the size of the alternators and associated equipment of short-circuit testing stations on a scale which could be exceedingly costly. Synthetic testing which, in effect, supplies current and voltage for the test from two independent relatively low power sources, offers a possible alternative solution to the problem involving a much lower order of expenditure. While there is considerable evidence that synthetic methods can reproduce the severity of conventional testing it has still to be shown that synthetic circuits can stimulate adequately the many factors involved in the proving of circuit breakers. Among the items of research equipment developed for circuit breaker testing is a compact design of restriking voltage indicator.

The important fundamental investigation of possible binary and ternary alloys other than those of the silicon-iron binary series, which might offer improved characteristics in soft magnetic core materials, continues. This work is being carried on mainly at the British Iron and Steel Research Association Laboratories at Sheffield. In relation to transformer noise, tests are being made to ascertain what correlation exists between magnetostriction and core vibration. These are being made on transformer cores having similar magnetic properties but widely different values of magnetostriction.

An extensive investigation has been made of the over-voltages which occur in high-voltage transmission systems as a result of switching operations. A critical résumé has been prepared of the amplitudes, wave shapes and frequency of occurrence of switching over-voltages in extra-high-voltage transmission systems. An automatic surge oscillograph has been installed on one of the 275-kV transmission lines of the British Grid which is equipped with automatically reclosing circuit breakers in order to obtain information about the over-voltages produced by high-speed reclosure. The Association's facilities for power system analysis, particularly complex transient problems, have been extended by additions to the network analyser or, as it is now termed, the 'Integrated Computer'.

Transient problems have been dealt with relating to 50-c/s a.c. railway electrification, switching surges on high-voltage d.c. submarine cables, rate of rise of restriking voltage on large-scale systems and the fault contribution from large induction motors. The analyser is no longer used for load flow and stability investigations, as computer programmes are now available for the solution of those problems on digital machines.

The rating of cables constitutes an important part of the work of the division dealing with lines and cables for power supply. A field investigation on the thermal behaviour of buried cables is being made in co-operation with various area electricity boards, the Central Electricity Generating Board and the Cable Makers Association. This investigation is concerned with the influence of soil moisture migration on the power-rating of cables buried directly in the soil and with the exploration of methods of mitigating thermal run-away due to drying out in the summer. Experiments have been made with 'backfill' materials with good thermal properties and promising results have been obtained with impermeable cover and weak mortar bedding.

One section of the programme of work on intrinsic safety has been completed by the investigation of a further nine inflammable gases, and all inflammable gases and vapours of industrial importance are now included in a British Standard Specification. Work on the relationship between circuit current and the probability of ignition has shown that the safety factor at present used ensures that the probability of ignition is as low as $1 : 10^{8}$. Investigations concerned with rotating machines comprise an investigation of unbalanced magnetic pull and the continuation of work on tooth ripple phenomena in alternators.

Among the non-industrial applications, electrical heating takes quite an important place. Various aspects of off-peak floor heating are now being investigated. Field trials of floor heating in multi-story flats have reached a stage which enables definite recommendations to be made regarding floor structure, floor and building insulation and cable spacing. A related problem, that of the static electrification of carpets, has been investigated during the year and a report issued. There is increased general interest in problems of static electrification resulting from warmer and drier atmospheric conditions in buildings, the development of certain new industrial processes and the widespread use of very readily electrified plastic materials. Means of heat storage other than floor heating are being investigated, in particular the use of the lime-water reaction.

The Association's work related to agriculture and horticulture continues to be directed towards crop conservation, equipment in livestock husbandry and controlled environment for livestock together with instrumentation and control in horticulture and the horticultural applications of heat and light. Very encouraging results have been obtained with the dairy heat pump.

Quite outside the normal range of the Association's activities, although deriving directly from earlier work on arc physics, and on lightning discharge, are the contributions to astrophysics made by Dr. C. E. R. Bruce. It has been demonstrated that the types of absorption spectrum lines which have since 1877 been regarded as evidence of rapid stellar rotation often derive from discharge-generated vortices akin to ball-lightning. A theory of ball-lightning

has been developed which appears to be in accord with all known observations.

A significant trend in the financial support given to the Association is evidenced by the large increase, relative to the general subscription income, in the specific contributions by industrial groups to specially sponsored programmes. This, to a great extent, reflects the wish of members, especially the larger ones, to exercise a greater measure of control over the application of the funds which they provide than is possible if they simply contribute to general funds through membership subscriptions.

J. Greig

DISTRIBUTION AND MOTIONS OF OH NEAR THE GALACTIC CENTRE

By J. G. BOLTON, F. F. GARDNER, R. X. McGEE and B. J. ROBINSON

C.S.I.R.O. Division of Radiophysics, University Grounds, Sydney, Australia

MEASUREMENTS with the Australian 210-ft. telescope have shown[1] a wide and deep absorption by OH in the radio spectrum of Sagittarius *A*. The absorption occurred over a region the angular extent of which was much less than that of the whole Sagittarius *A* source, and it appeared likely that only the 'core' component[2,3] of the source was being absorbed. However, the original observation did not reveal the overall angular extent of the absorbing gas.

We have since observed OH absorption in other parts of the Sagittarius *A* complex at 1,667 Mc/s, 1,665 Mc/s and at 1,612 Mc/s, the frequency of one of the recently detected[4] satellite lines of OH. Absorption has been detected at all longitudes between $l^{II} = 358°\ 30'$ and $l^{II} = 2°\ 30'$, and for latitudes between $b^{II} = +10'$ and $b^{II} = -30'$. As was found[1,4] for the central source of Sagittarius *A*, only some of the components of the continuum radiation were absorbed, and the ratios of the intensities of the lines were smaller than the theoretical values. The OH is distributed in apparently discrete clouds with characteristic velocities. An unexpected result was that the velocities of the various clouds are constant over a range of galactic longitude, in contrast with the velocity distribution deduced from 21-cm measurements of neutral hydrogen.

Observations at intervals of 10′ arc were made at 1,665 and 1,667 Mc/s using a modified receiver with 48 channels[5] of band-width 37 kc/s. Absorption was found at radial velocities from +160 to −200 km/s. Partially resolved minima in the profiles at a number of discrete velocities can be traced continuously over one to two degrees in longitude. An example is given in Fig. 1; contours of the 'apparent opacity', at 1,667 Mc/s, of the gas with radial velocity near −135 km/s are superimposed on a map of the continuum at 1,670 Mc/s. (The continuum measurements were made during the present survey with a wide-band section of the receiver). The apparent opacity is defined as the amplitude of the observed absorption divided by the continuum temperature in the same direction; as in general only part of the continuum radiation is absorbed, this ratio will be a lower limit to the true opacity. The gas responsible for absorption near −135 km/s extends south of the galactic plane in a band 20′ arc wide, the opacity being appreciable between $l^{II} \doteqdot 359°\ 10'$ and $l^{II} \doteqdot 0°\ 30'$. No contours are shown for the weaker absorption outside this longitude range. The apparent opacity reaches peak values of about 0·4, corresponding to an optical depth of at least 0·5.

Clouds of similar extent are observed at a number of other velocities. At negative velocities the gas is found mainly south of the plane in the longitude range from 358° 30′ to 1°. For positive velocities the clouds are observed to lie close to the plane, in the longitude range $l^{II} = 359°\ 50'$ to $l^{II} = 2°\ 30'$. These clouds have dimensions of approximately 200 parsecs at the distance of the galactic centre.

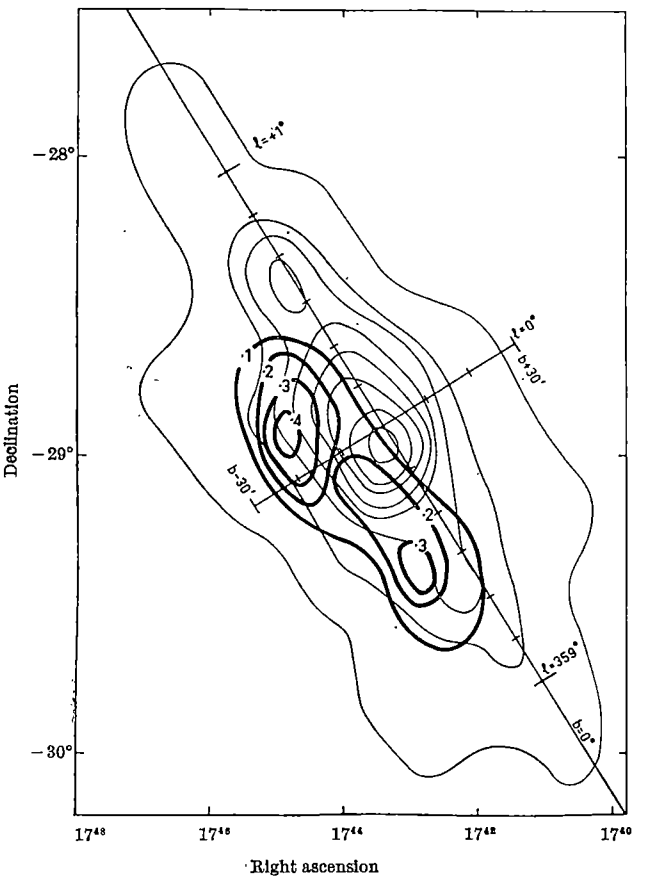

Fig. 1. Contours of the 'apparent opacity' at 1,667 Mc/s of the gas with a radial velocity near −135 km/s (1964·5 co-ordinates)

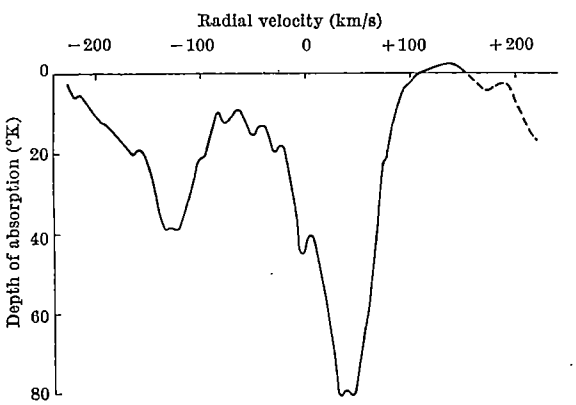

Fig. 2. Absorption profile of Sagittarius *A* at 1,667 Mc/s, measured with a band-width of 37 kc/s. For velocities greater than +150 km/s the profile overlaps that of the 1,665 Mc/s line

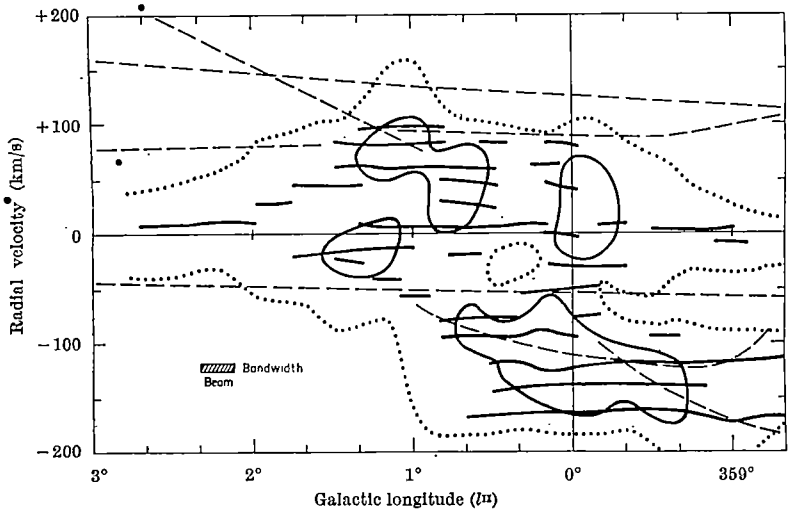

Fig. 3. Galactic longitude *v.* velocity diagram, showing for $b^{II} = -0° 10'$ the areas of strong 1,667-Mc/s absorption (enclosed by contours) and the boundaries of the observed absorption (dotted lines). The thick lines join discrete minima on the profiles, while the dashed lines represent the velocity variation of HI observed[7] at 1,420 Mc/s

Goldstein *et al.*[6], observing the central source of Sagittarius *A* with a 54′ arc beam, found an absorption at −120 km/s of intensity comparable to the deep minimum at +40 km/s. The complete profile for this source, observed with the 12′·5 arc beam at 1,667 Mc/s, is shown in Fig. 2. With the greater resolution the localized[1] absorption near +40 km/s is enhanced relative to that at high negative velocities. Both the strong absorption features are seen to be blends of several components not revealed in the earlier investigations[1,6].

An impression of the motions of the gas may be gained from the radial velocity *v.* galactic longitude plot at $b^{II} = -0° 10'$ given in Fig. 3. The diagrams for other latitudes are similar. The extent of the absorption is indicated by the four closed contours, delineating areas where the absorption is greater than 7° K, and by the dotted lines showing where absorption can no longer be detected. The thick lines running across the diagram join the radial velocities of discrete minima on the profiles; for clarity no attempt has been made to indicate the intensity at the minima. The resolutions in angle and radial velocity are shown on Fig. 3. For comparison, the dashed lines indicate the behaviour of the main emission features of neutral hydrogen, for $|V| > 50$ km/s, as deduced by Rougoor[7] from 21-cm observations with a beam-width of 34′ arc.

A striking characteristic of the diagram is the constancy of the velocity of the absorption features. A close correspondence between the OH and HI velocities is seen between +90 and 100 km/s, and near −50 km/s. For velocities greater than +100 km/s no marked OH absorption is seen; the hydrogen at these velocities also shows no appreciable absorption[8], and is believed to lie beyond the centre and to be moving away from it. However, the OH observed between 0 and +100 km/s must lie in front of the centre and be moving inwards.

At higher negative values, up to −170 km/s, the constancy of velocity of the several partially resolved minima of the OH profiles (Fig. 2) contrasts with the 21-cm observations. The latter show steep gradients of velocity with longitude, interpreted[7] as a "rapidly rotating disk" and a "contracting or expanding arm at −110 km/s". The presence of apparently discrete velocities conflicts with the model proposed by Rougoor and Oort[8] for the motions of the gas in the central region. It is clear that radial motion is as marked as any component of rotation about the centre. The 21-cm measurements have possibly suffered from confusion of a mixture of emission and absorption, and inadequate resolution. In this survey no OH emission greater than 2° K was found, so that the absorption stands out clearly.

INTERACTION BETWEEN LOWER AND UPPER TROPICAL TROPOSPHERES

By C. R. V. RAMAN and Y. RAMANATHAN

India Meteorological Department, International Meteorological Centre, Bombay

ATTENTION has been directed by a number of workers to the concentration of easterly winds in the upper troposphere (150–100 mb levels) over the tropics into maxima, exhibiting jet stream characteristics. Such maxima in easterlies generally occur and are most prominent in the northern summer (July and August) along the southern periphery of the immense anticyclones over south Asia and north Africa. Occurrence of easterly wind maxima has also been noted in the Caribbean. These are sporadic and have been described as the return current of west wind maxima around the periphery of the sub-tropical anticyclone over the North Atlantic (Bermuda high).

Upper divergence in the favourable regions of the east-wind maxima over the tropics has been utilized in explaining low-level weather sequences on a cause-and-effect basis. In a case study, Alaka[1] cites examples of vertical motion associated with an easterly jet being directly favourable for organized convection over the Caribbean and western part of the Gulf of Mexico. In explaining conditions leading to the onset of the summer monsoon over India, monsoon rains as well as intensification of monsoon depressions, Koteswaram[2] visualizes the pre-existence of favourable regions of vertical motions in the upper troposphere brought about by east-wind maxima, perturbations in the upper easterlies and their movements. Summarizing the applications of similar mechanisms, Reiter[3] states that "the Indian monsoonal rains and the rainy season in equatorial Africa are dependent on the 'Tropical Easterly Jet' and its position and not so much on the zenithal march of the Sun". These are instances of extension to the tropics and near

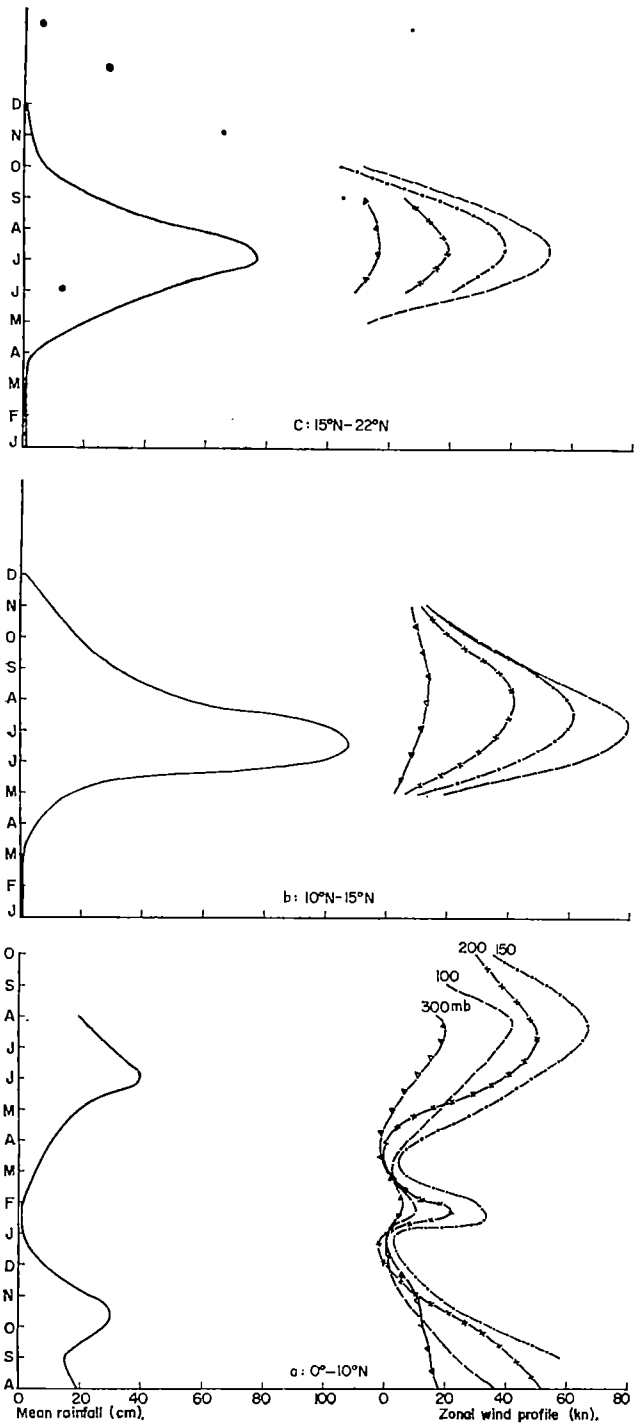

Fig. 1. Mean monthly rainfall distribution and profiles of upper tropospheric mean zonal components (east) along 77° E. (west coast of India)

equatorial regions of middle latitude concepts involving influence of changes in upper air on lower levels.

In an investigation of the upper easterlies during July 1957, Raman[4] directed attention to the absence of marked wave-type perturbations in the easterly current unlike the middle latitude westerlies. He also found that during the summer monsoon period, the upper tropospheric east wind maxima underwent a phase of generation and degeneration in an interval of five to nine days. Parthasarathy[5] pointed to the weakening of high-level easterlies over peninsular India during 'breaks' in the south-west monsoon when precipitation over the southern slopes of the Himalayas and sub-montane regions is copious but is practically absent over the plains and west coast of India. Again, reasons for the lateral displacements of east-wind maxima over south Asia during summer, occurrence of easterlies of jet magnitude over the equator, far removed from the sub-tropical anticyclones have remained obscure. Explanation is also necessary for the occurrence of east wind maxima of jet magnitude over tropical Australia and Africa, equatorward of the sub-tropical anticyclones in the southern hemisphere.

Towards a better understanding of some of these aspects, an examination was made of the behaviour of the upper tropospheric easterlies from south-west Pacific to equatorial West Africa during the IGY and IGC period (1957–59). It was found that the time sequence of the upper event to the lower effect was not always realized; for example, monsoon rains along the west coast of India did not appear always to result from changes in the upper troposphere. Instances were not uncommon when strengthening of the upper easterlies was noticed some time after occurrence of heavy rain along the west coast of India. Experience with daily analysis of extended weather charts (20° E. to 155° E. and 50° S. to 45° N.) at the International Meteorological Centre (IMC) during 1963 lent support to such a possibility, and suggested a re-thinking on the possible interaction between the lower and upper tropical tropospheres. In tropical areas, where the land–sea contrast is marked and convective processes are common, it became probable that weather sequences in the lower troposphere may precede and even cause significant changes in upper tropospheric circulations.

Climatological Aspects

As a first step towards investigation of such a possibility, the mean monthly rainfall at stations along the west coasts of Ceylon and India in the latitudinal belts 0–10° N., 10–15° N. and 15–22° N. was compared with the upper tropospheric winds along 77° E. (Fig. 1). The rainfall curve was obtained by averaging the mean monthly rainfall amounts of all available stations in each belt. In the near equatorial region (0–10° N.) (Fig. 1*a*), this curve exhibits a double peak, one during May–June and another during October–November. An explanation for this lies in the double traversal of the Sun in the near equatorial regions during its annual march and the activation of the near equatorial trough. The zonal components of available winds (east) in the layer 300 mb to 100 mb for Gan (00° 41′ S.), Colombo (06° 54′ N.) and Trivandrum (08° 29′ N.) also display a double peak, one during July–August and another during January–February. However, in the latitudinal belts (10–15° N. (Fig. 1*b*) and 15–22° N. (Fig. 1*c*), the monthly march of mean rainfall along the coast as well as the zonal wind in the upper troposphere display only single maxima. It is interesting to note that along 77° E. (typifying the Indian monsoon area) climatologically, the upper tropospheric wind is strongest in the latitudinal belt where the rainfall is also heaviest along the coast. In all the three zones, from the climatological point of view, the summer rainfall peak occurs first and the maximum east wind in the upper troposphere shortly thereafter. This fits with the observation of Raman and Dixit[6], who noticed a lag between low-level troughs and stabilization of upper anticyclones in the Indian monsoon area. However, it is felt that in the equatorial belt, the time gap between the rainfall peak in the transition months October–November and the wind maximum during January–February would get reduced when long period mean wind data for Colombo and Gan become available. Similar characteristics are observed along 100° E. (along the coasts of Arakan and Tenasserim) (Fig. 2); also along 30° E. and 10° E. (tropical Africa). In this context, it is interesting to note that Davies and Sansom[7] observed easterly wind maxima over Nairobi in two distinct epochs, July–September and December–March. Hay[8] found maxima in the upper tropospheric

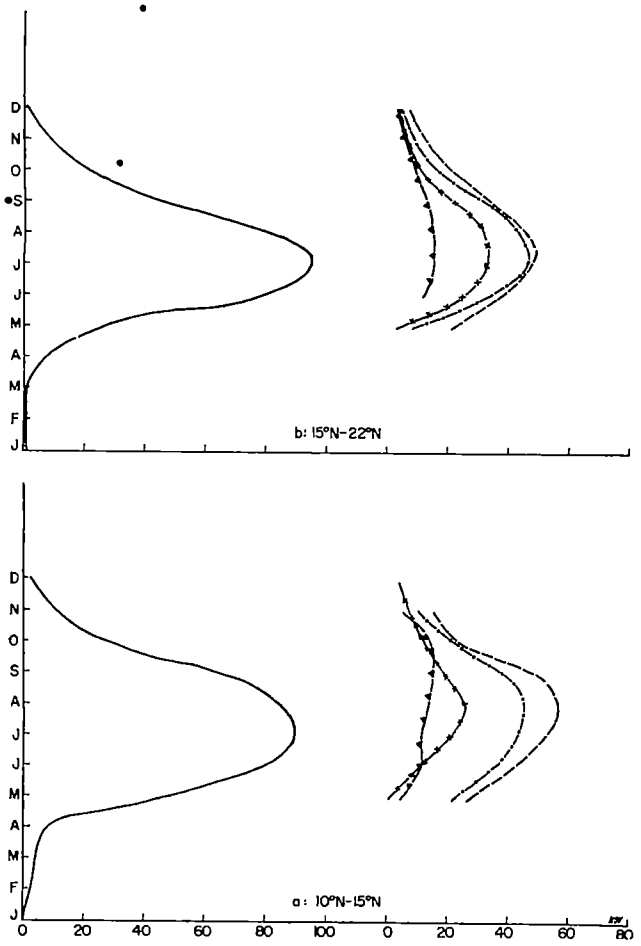

Fig. 2. Mean monthly rainfall distribution and profiles of upper tropospheric mean zonal components (east) along 100° E. (Arakan and Tenasserim coast)

easterlies over Singapore both during the months of south-west monsoon, June–August, and of the north-east monsoon, December–February. He, however, found that over Hong Kong (22° 18′ N.) east-wind maximum occurred only once in the year, and that in the summer months. A preliminary examination of upper wind data of Gan for three years reveals that strong upper tropospheric easterlies occur on individual days both during the northern and southern summer months.

Synoptic Examination and Quantitative Evidence

The climatological indication thus obtained was then put to a synoptic test. For this purpose, it was sought to examine the relationship, if any, between the precipitation and upper tropospheric zonal winds on a day-to-day basis, in the latitudinal belt 1° S.–22° N. during the mid-monsoon months, July–August of 1961, 1962 and 1963. To ensure homogeneity, rainfall data only of coastal observatory stations (numbering 22) along the west coast of India were utilized. Rainfall amounts for the 24-h period ending 0300 G.M.T. of each day were plotted against latitude of the recording stations and from the resulting curve the latitudes of maxima of rainfall along the coast were located. The latitude of east-wind maximum was arrived at from daily wind profiles of 200 mb, 150 mb, 100 mb and 70 mb along the mean meridian 77° E. Where data of 00 G.M.T. were not available, those of 12 G.M.T. were used in drawing the profiles. In order to assess quantitatively the interrelationship, if any, between the precipitation and easterly wind maxima, a set of correlation coefficients, as here listed, was computed.

The latitude of easterly wind maximum of each day was correlated with the latitude of highest rainfall along the west coast of India, recorded over a 24 h period ending 0300 G.M.T. of (i) previous day, (ii) next day, (iii) same day. Out of a total of 186 days in July–August 1961–63, wind data were available for comparative examination on about 100 occasions.

Table 1. Correlation between latitude of upper tropospheric east-wind maximum on a day with the latitude of maximum rainfall recorded at 0300 G.M.T. of (i) previous day, (ii) next day and (iii) same day along the west coast of India

Month/year	East-wind maximum of date with* (a) Previous date's precipitation maximum	(b) Next date's precipitation maximum	(c) Same date's precipitation maximum
July 1963	0·76	0·21	0·64
August 1963	0·90	0·23	0·54
July 1962	0·86	−0·11	0·21
August 1962	0·81	0·55	−0·06
July 1961	0·87	0·29	−0·27
August 1961	0·56	0·23	0·04

* (i) Total number of cases for which complete wind data were available for comparative study: 100.

The results are presented in Table 1.

It will be seen from the highly significant correlation coefficients in column (*a*) of Table 1 that precipitation maximum on a day seems to be associated with the concentration of upper tropospheric winds into a maximum probably on the next day only. The contribution of the day's maximum wind to the next day's precipitation maximum does not appear to be as much. Results for 100° E. for July–August 1963, given in Table 2, point to the same inference.

The general weakening of the east-wind maximum during the northern summer months over Saudi Arabia and Ethiopia, where cloudiness and rainfall are much less than along the west coast of India, the disappearance of the 'easterly jet' over the Sahara immediately to the west of Khartoum and its reappearance over Nigeria, which lies in the monsoon régime, then seems to follow a logical pattern.

The daily graphs of precipitation and the east-wind maxima along 77° E. and 100° E. bring out the following features. These are illustrated in Fig. 3 with the help of typical examples chosen out of a large sample. (i) Peakiness of 24-h rainfall along the coast on a day is reflected in the upper troposphere as a concentration of east wind into a maximum the next day. The latitude of east-wind maximum lies about 1–3 deg. south of the latitude of the recorded maximum of previous day's rainfall (Fig. 3*a*). This fits with Koteswaram's observation of the occurrence during 'breaks' of the axis of the maximum east wind at a more northerly location than usual, that is, closer and to the south of the rain excess region in the Himalayan slopes. (ii) The pattern of rainfall distribution along the coast with more than one maxima, as often occurs during the south-west monsoon, is largely reflected in the next day's wind profile as well (Fig. 3*b*). IMC charts also exhibited similar characteristics on a number of occasions, with well-defined maxima in easterlies near the equator, in the latitudinal belt 5–15° N. and farther north. Such occurrences were not confined to the monsoon months alone but were observed in other months as well. East-wind maxima were observed over Kenya, Malaysia, Indonesia and north Australia. Reconnaissance upper wind observations by the Indian Air Force during July–August 1959 also pointed to the occurrence of distinct east-wind maxima along different latitudes over south peninsular India. (iii) When rainfall along the coast is small and negligible, concentration of the easterlies on the next day is significantly absent on a number of occasions (Fig. 3*c*).

Table 2. Correlation between latitude of upper tropospheric east-wind maximum on a day with latitude of maximum rainfall recorded at 0003 G.M.T. of (i) previous day, (ii) next day and (iii) same day, along Arakan, Tenasserim and Malaysia coasts

Month/year	East-wind maximum of date with* (a)	(b)	(c)
July and August 1963	0·68	0·43	0·47
July 1963 alone	0·86	—	—

* Total No. of cases for which complete wind data available for comparative study: 46.

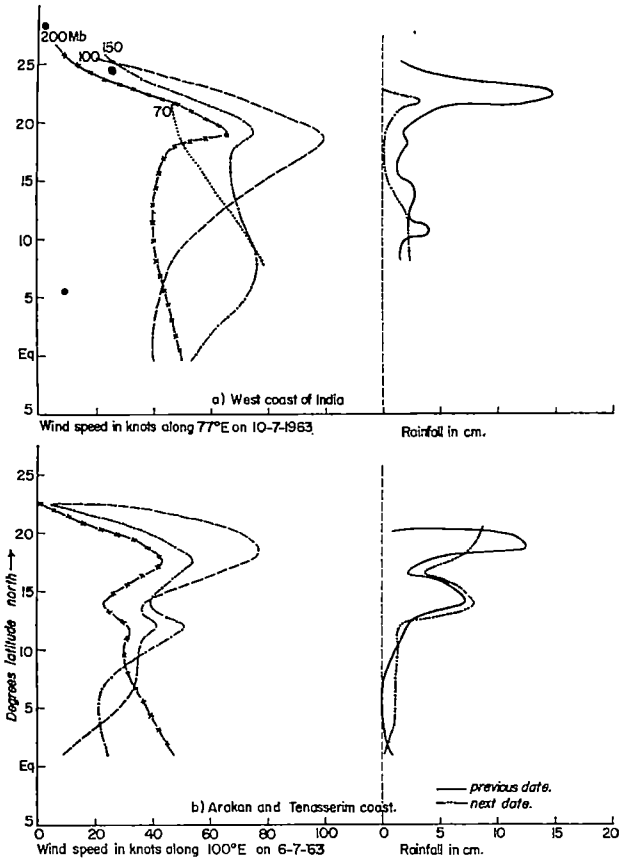

Fig. 3. Relation between summer monsoon rainfall along coast and upper tropospheric easterlies

An attempt was then made to synthesize the daily data into an average picture. With reference to the latitude of a day's east-wind maximum, discrete precipitation amounts from available data were extracted at one-degree intervals over a five-degree belt north and south, for the previous day and the next day. Mean monthly profiles for the period of study are presented in

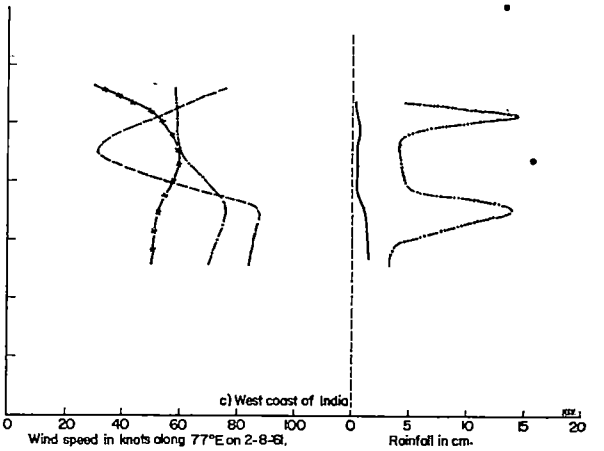

Fig. 4. It is clear that the axis of east-wind maximum lies on the average to the south of the previous day's recorded rainfall maximum (Fig. 4*a*). The average curves for the next day's rainfall do not exhibit any systematic or consistent relationship with the axis of maximum east wind (Fig. 4*b*). Herein it is pertinent to note Bond's[9] reference to the prior occurrence of strong surface pressure gradients, strong low-level westerlies and existence of mid-tropospheric vortices in describing easterly jet over Darwin. It seems possible now to offer a physical explanation to the observational evidence provided by Bond. Ramsey[10] has linked the position of the 'Intertropical front' with easterly jet over the far east and Indonesia.

While it is not possible to rule out the influence of the upper troposphere on conditions nearer ground, this investigation shows that there is a significant contribution to the upper level patterns by precipitation. This contribution probably results from the release of large amounts of latent heat from excessive cloudiness and copious precipitation. Such latent heat release may be expected to cause heating of the upper troposphere, advective transport of heated tropospheric air and consequent changes in upper tropospheric circulations[11]. This concept is being carefully considered in a few investigations in IMC. Further, quantitative assessments of the contribution of latent heat for production of kinetic energy are being made and the results will be published elsewhere.

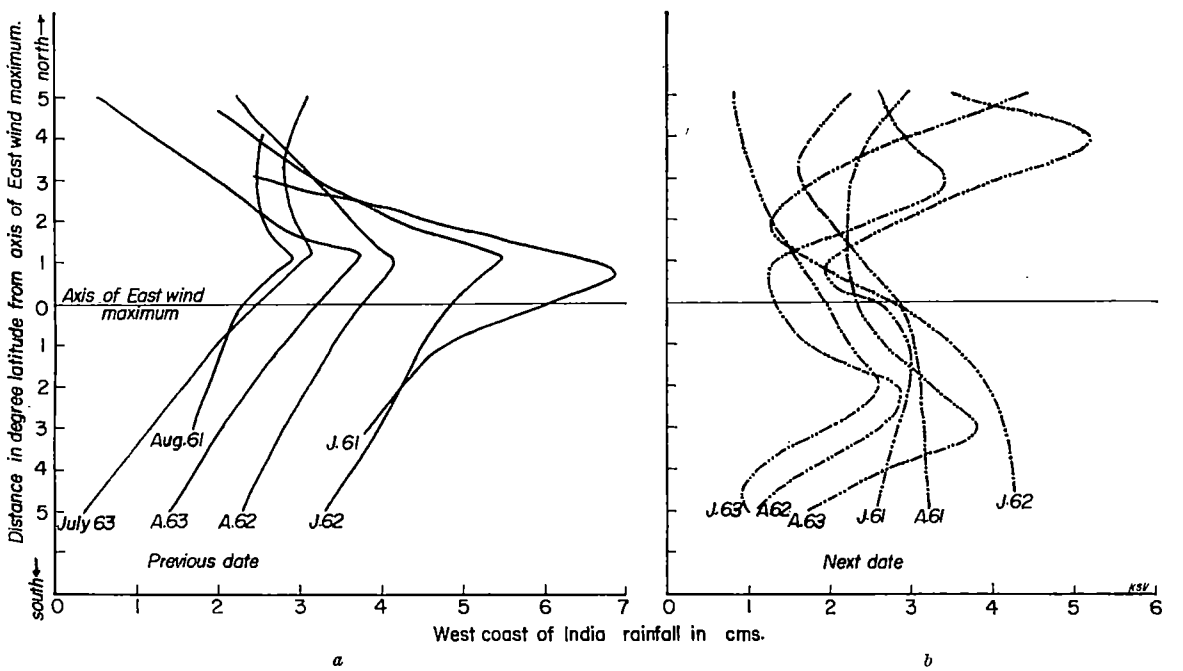

Fig. 4. Mean distribution of rainfall along west coast of India about the axis of strongest upper tropospheric easterlies in summer monsoon

The foregoing preliminary investigation provides a new point of view in the examination of low-latitude disturbances and strongly suggests that weather sequences in the lower troposphere may frequently cause changes in the upper tropospheric circulations.

We thank Dr. C. S. Ramage and Dr. P. R. Pisharoty for their advice.

ELECTRICAL CONDUCTION IN THIN AGGREGATED METAL FILMS

By Dr. ROBERT M. HILL
Electrical Research Association, Leatherhead, Surrey

An electrical field effect has been observed between discontinuous aggregated thin evaporated metal films of gold, and the substrate on which they were deposited. The effect is similar to that observed by Cox[1] and Bonfiglioli and Malvano[2] for continuous films, but the magnitude of the change in resistance involved is much larger. It suggests that conduction in the aggregated films occurs by electron tunnelling through the substrate and not directly between the metal aggregates as suggested by Neugebauer and Webb[3] and Hartmann[4].

The gold films were prepared in a vacuum of about 10^{-6} torr; soda and borosilicate glasses were used as the substrates. The substrates were cleaned with detergent solutions and baked in vacuum at a temperature of 320° C for a period of 4 h; they were then cooled to 300° C and the films deposited. The electrical resistance of the specimens was monitored during deposition, and evaporation was stopped when the resistance fell to about 5×10^3 ohms. Measurements of the films were then carried out over a lower temperature range (20°–250° C) so that no further structural reorganization took place. The metal films were removed from the vacuum after the measurements were completed and were examined by electron microscopy. They were completely aggregated with an average particle size of 260 Å, and an average spacing of 52 Å.

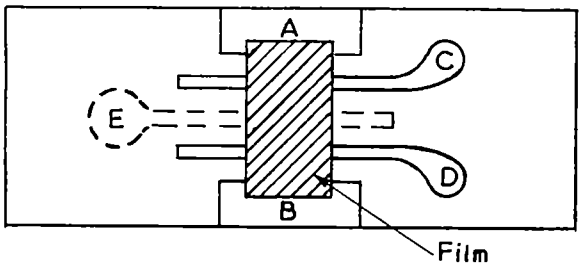

Fig. 1. Diagram of the evaporated film and the electrodes

The substrates carried fired-on electrodes, as shown in Fig. 1. *A* and *B* are current input and output electrodes, *C* and *D* are for voltage sensing. Electrode *E* was an extra electrode fired on to the back of the substrate. It was found that the resistance of the film between *C* and *D* could be varied, in a completely reproducible manner, by impressing a d.c. voltage on the bias electrode *E*. To remove uncertainties from leakage currents an a.c. signal at 50 c/s was used to measure the film resistance, and the driving potential was obtained from the ends of a centre-tapped transformer, the centre tap of which was earthed. The d.c. bias was supplied from a battery, one terminal of which was also earthed.

The variation of resistance as a function of bias voltage for the two glasses, and for a range of temperatures, is shown in Fig. 2. The changes in resistance of gold films on soda glass were small, but larger changes were observed using good-quality borosilicate glass (Corning No. 7740).

We have attempted to explain the results by applying the theory of amorphous dielectrics[5–7] to the system. If the bulk of the glass is assumed to contain a large number of trapping sites between the quasi-conduction and valence bands, then it can be deduced that the most likely distribution of traps is of a double exponential form, that is, many traps near the band edges and a few in the middle of the band gap. Thus the energy required to activate an electron from one trap to the trap of the next highest

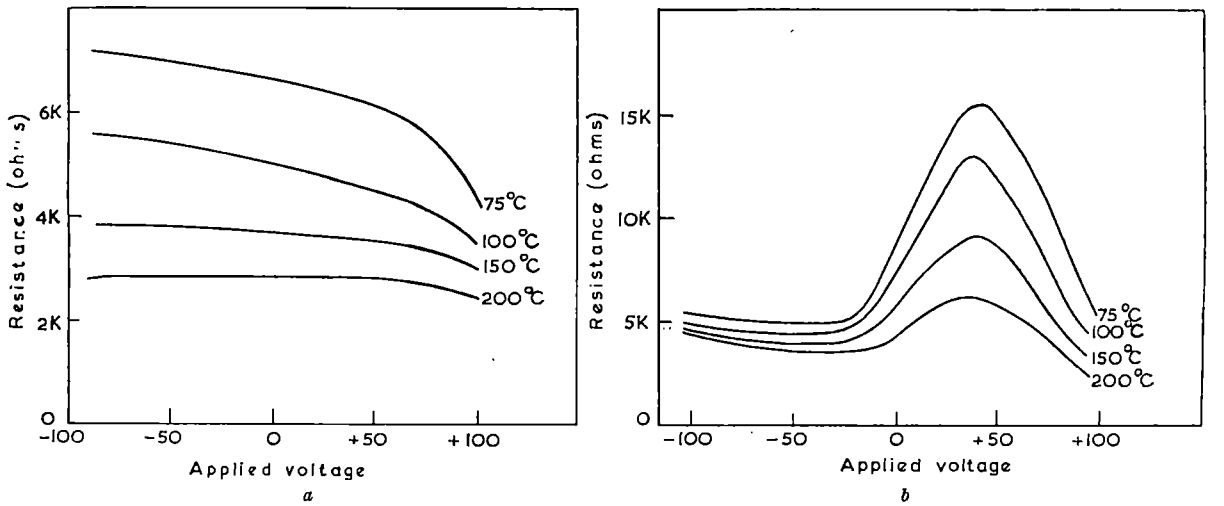

Fig. 2. The variation in resistance of gold films as a function of applied bias voltage and temperature. *a*, Soda glass 0·050 in. thick; *b*, borosilicate glass 0·020 in. thick

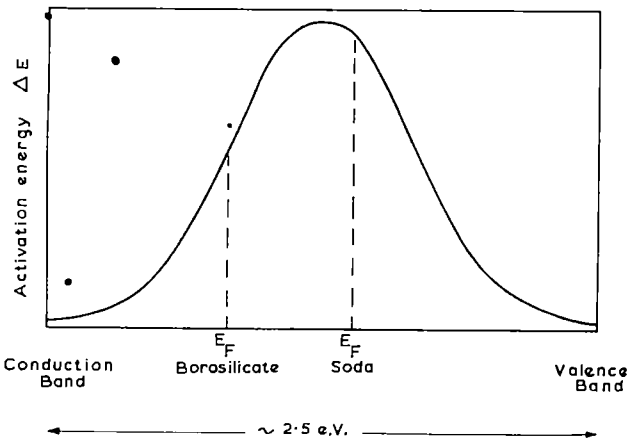

Fig. 3. The activation energy required for the transfer of an electron from trap to trap as a function of position in the normally forbidden energy gap

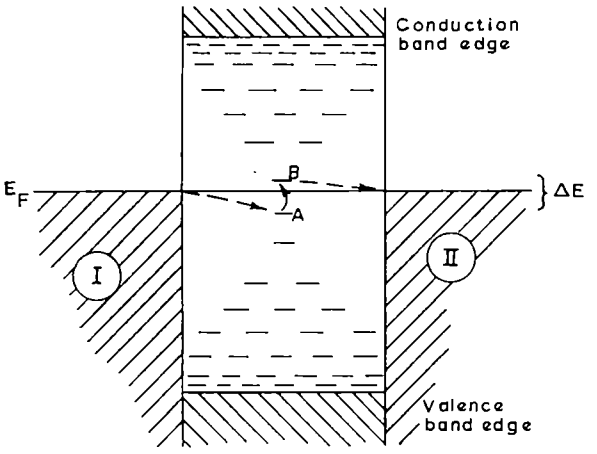

Fig. 4. Schematic energy diagram for the transfer of an electron from aggregate I to aggregate II by means of a trap jump A–B

energy, ΔE, will depend on the position of the trap in the band gap (Fig. 3). The energy diagram for the system is shown in Fig. 4, where I and II represent two adjacent metal particles separated by the glass. The Fermi-levels in the metal particles are shown at E_f, and the Fermi-level in the glass becomes aligned with these by charge transport between the metal and the bulk of the glass. As we are only considering the region just below the metal–glass interface we can neglect band bending effects. The applied potential between the aggregates is small (about 2×10^{-5} V) and can also be neglected. If a trap site were exactly located at the Fermi-level direct tunnelling could occur from the free thermal electrons above the Fermi-level in I, via the trap, with a much smaller effective impedance than for simple tunnelling between aggregates[8]. The process would be non-thermally activated. If, however, there is no trap in this position electron tunnelling into trap A can occur, as shown in Fig. 4, the small energy difference being lost to the glass lattice structure. Tunnelling from A into particle II cannot take place readily because there is no available energy-level within II at the energy value of A. Before this can happen the electron has to be activated into trap B, the nearest available trap of energy higher than E_f. The process then becomes thermally activated and a negative temperature coefficient of resistance would be expected, and is experimentally obtained for aggregated films.

The positions of the Fermi-levels within the glasses can be obtained from the d.c. activation energies (Fig. 3). On applying a positive bias to E the Fermi-level in the glass is lowered towards the quasi-valence band and the activation energy for conduction follows the curve shown in Fig. 3. As the Fermi-levels for the two glasses we are using lie on opposite flanks of the curve, we obtain agreement with the form of the experimental measurements shown in Fig. 2.

The resistance of the films was found to obey the usual relationship:

$$R = R_0 \exp (\Delta E/kT)$$

so that at any one temperature a change in the activation energy ΔE would give an exponential change in resistance. The activation energy was measured for various bias conditions and the calculated resistance values gave good agreement with the experimental results.

At present we are not able to calculate the number of trapping sites that are involved in the process, but it is possible to calculate the ratio of the number of active traps for the two glasses. At zero bias conditions the ratio of traps for the borosilicate and soda glasses are 5·0/12·5, whereas the sodium concentration in the borosilicate glass is 5 per cent and in the soda glass is in the range 10–15 per cent.

It appears that conduction in aggregated films occurs through the substrate, and is aided by the presence of trapping centres in the glass. Bonfiglioli and Malvano[2] found some evidence of interaction with surface traps on mica using evaporated films of a few ohms resistance, that is, a continuous structure. By using the discontinuous structure and a non-crystalline substrate we have enhanced the effect by some three orders of magnitude. We intend to use ultra-high-vacuum techniques to remove any uncertainties arising from surface layers and a wider range of glasses of known composition in order to test the experimental model we are proposing.

I thank Mr. G. Siddall and Mr. A. M. Cassie, of this laboratory, for their advice, and Mr. J. S. Cleaver for assistance in the electron microscopy investigation.

DEOXYRIBONUCLEIC ACID IN PLANT NUCLEOLI

By Dr. JOHN McLEISH
John Innes Institute, Bayfordbury, Hertford, Herts.

THE view that nucleoli contain ribonucleic acid (RNA) but no deoxyribonucleic acid (DNA) is based mainly on staining properties and the results of autoradiography. In general, nucleoli are Feulgen-negative although Feulgen-positive inclusions have occasionally been found in both plant[1] and animal[2–4] cells. Furthermore, nucleoli exhibit little, if any, residual basophilia after extraction of the RNA by ribonuclease (RNase)[5]. It is also known that under conditions in which radioactive precursors of DNA, such as tritiated thymidine, are readily incorporated into the chromosomes, no comparable incorporation into the nucleoli takes place.

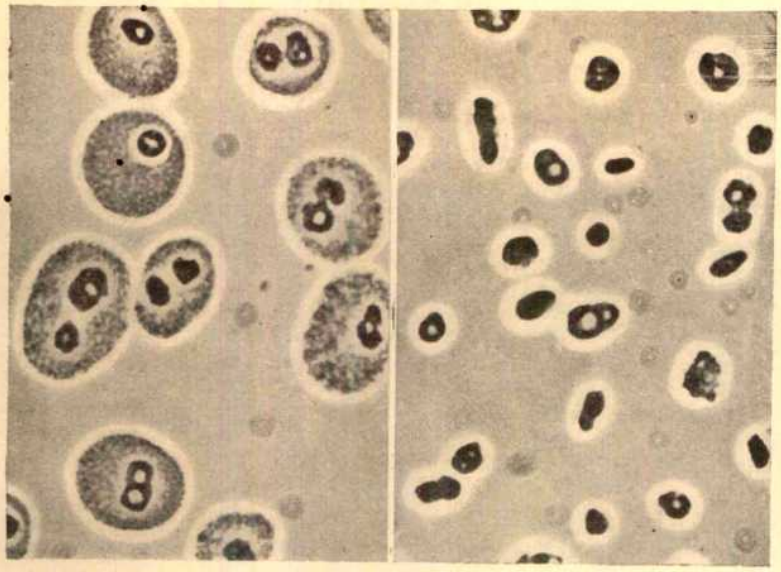

Fig. 1. Nuclei (left) and nucleoli (right) isolated from root apices of *Vicia faba* (phase-contrast; × *c.* 600)

On the other hand, DNA has been estimated chemically in nucleoli isolated from pea tissues[6,7] and rat liver[8,9]. In these cases, however, there has been some uncertainty as to how much of the DNA is truly nucleolar and how much is derived from accompanying chromosomal material such as the 'nucleolus-associated chromatin'[10]. In fact, it has been suggested that the nucleolus, together with any accompanying chromosomal components, should be considered as a discrete unit and called the 'nucleolar apparatus'[7]. It has never been clearly demonstrated, however, that the nucleolus still contains DNA after any accompanying materials, with the properties of chromosomal DNA, have been excluded. At least the nucleoli isolated by Rees *et al.*[9] may be free from high-polymer chromosomal DNA since they stain pink instead of blue-green with methyl-green-pyronin[11].

It is also significant that changes in the structure of both animal[12] and plant[13] nucleoli have been observed as the result of deoxyribonuclease (DNase) treatment.

The purpose of this article is to describe the results of chemical and cytochemical measurements which have led to the conclusion that nucleolar DNA may be of more widespread occurrence in plants than had hitherto been supposed. The measurements were made on nucleoli isolated from formaldehyde-fixed roots. There is reason to believe that such a fixation helps to prevent subsequent loss of both DNA and RNA[14].

The main experiments were carried out using the apical 2-mm segments of lateral roots of *Vicia faba* plants growing in vermiculite at 20° C. These root-tips were collected in ice-water and then fixed for 40 min in ice-cold 1·5 per cent formaldehyde in M/60 phosphate buffer at *p*H 7·0. They were then washed in 1 mM phosphate buffer at *p*H 7·0, to remove the formaldehyde, and crushed in a drop of the same buffer in a press[14]. The exudate, containing nuclei and cytoplasmic particles, was then diluted with more of the 1 mM buffer and clean samples of nuclei (Fig. 1) collected by three successive centrifugations, of 3 min each, at 500*g*. The nuclei were then resuspended in the 1 mM buffer and shaken for 15 min in a Mickle disintegrator (50 c/s). Glass beads were not used. This shaking disrupted the nuclei and dispersed the chromosomal material, but did not damage the nucleoli, which could be collected by centrifugation for 5 min at 1,500*g* (Fig. 1). All the operations were carried out in a cold room at 3° C. A small proportion of nuclei (0·5–2 per cent) was found to remain intact and could not be broken even with prolonged periods of shaking. Although it was possible to eliminate these contaminant nuclei by differential centrifugation, this led to some loss of the larger nucleoli and also increased the time taken for the whole isolation procedure. These nuclei were therefore allowed to remain and a small correction was applied to the final estimation of nucleic acid content in the nucleoli. The nuclei which resisted disruption did not appear to be derived from one type of cell in the roots since, when stained in Feulgen, microphotometry revealed a bimodal distribution and a mean stain value identical with that given by random samples of nuclei which had not been shaken.

The amounts of both DNA and RNA in the isolated nucleoli were determined by a modification[14] of the Schmidt–Thannhauser procedure[15]. The results of 15 separate determinations (Table 1) indicated that there is twice as much DNA as RNA. This is the same ratio as that found in rat liver nucleoli by Rees *et al.*[9]. In a second series of determinations, nucleoli were first washed in ice-cold 0·2 N perchloric acid and defatted before being incubated with RNase. Extraction of the RNA was then followed by extraction of the DNA by means of DNase. The quantities of the two nucleic acids determined in these two extracts were found to agree with those determined by the Schmidt–Thannhauser procedure (Table 1).

Approximately 17 per cent of the total DNA and 40 per cent of the total RNA of the nucleus is nucleolar. These figures are similar to those reported for *Pisum sativum*[7]. Estimations of nucleic acid concentration in nuclei and nucleoli have been based on measurements of total dry mass by means of interference microscopy (Table 2). These show that the concentration of RNA in the nucleoli is about three times higher than that in the rest of the nucleus, whereas the concentration of DNA in these two regions is about the same. Previous estimates of nucleic acid concentration in nucleoli have been lower than those found in *Vicia*. In a number of different species, concentrations of RNA of between 2 and 10 per cent have been reported[6,8,16–19]. Concentrations of DNA of 17 and 20 per cent[8,9] have been reported for rat liver nucleoli, but in the nucleoli of pea embryos, DNA is said to represent only 0·2 per cent of the total contents[6]. It is possible that more differences of this kind between species, and between tissues having different metabolic activities, will be found.

It should be mentioned here that, in the course of these experiments, some discrepancies were found which have

not yet been satisfactorily explained. On two occasions, using the Schmidt–Thannhauser procedure, a DNA : RNA ratio of exactly 1 : 1 was found in the nucleolar samples although the conditions of growth of the plants and the methods of isolation and extraction were apparently the same. In two other cases, samples of DNA extracted enzymatically from nucleoli gave a diphenylamine reaction of approximately twice the intensity expected from the ultra-violet absorption. Preliminary investigations suggest that this was not due to the presence of a contaminant.

Adenine, guanine, cytosine and thymine have been identified in the nucleolar DNA fractions by chromatographic analysis. The DNA, recovered either by the Schmidt–Thannhauser procedure or by enzymatic hydrolysis, was heated for 1 h in 0·1 N sulphuric acid at 100° C and the free purine bases precipitated as silver salts[20]. The purines, recovered by heating the precipitate in 1 ml. of N hydrochloric acid at 70° C for 15 min, were found to account for 50 per cent of the ultra-violet absorption of the original DNA solution. They were separated from one another on Whatman No. 1 filter paper using a descending solvent system consisting of methanol : ethanol : water : conc. hydrochloric acid (50 : 25 : 19 : 6)[21]. To recover the pyrimidine bases, further DNA samples from the isolated nucleoli were hydrolysed for 30 min in 5 per cent trichloroacetic acid at 75° C. The pyrimidine deoxyriboside phosphates were first precipitated as barium salts[20], and then freed from barium by dissolving them in water containing the NH_4^+ salt of 'Dowex 50'. The resin was then spun off and the supernatant dried down and hydrolysed with 98 per cent (w/v) formic acid for 2 h at 175° C. This hydrolysate was then evaporated to dryness, redissolved and the pyrimidine bases separated from one another on Whatman No. 1 filter paper using the descending solvent system consisting of ammonia in water-saturated *n*-butanol[22]. Each of the four bases was identified by its ultra-violet absorption spectrum after elution from the chromatogram in 0·01 N hydrochloric acid. Although not more than 30 per cent of the expected quantity of pyrimidines could be recovered by barium precipitation or other methods, it is difficult to believe that this is a true indication of the pyrimidine content; the results of all the other measurements, with the exception of the anomalous diphenylamine figures mentioned earlier, indicate that the nucleolar DNA is in a normal double-stranded form. However, the presence of single-stranded nucleolar DNA cannot be ruled out entirely and, with this possibility in mind, physical measurements and more intensive investigations of the base composition have now been started.

In order to see whether or not these nucleoli could have become contaminated by chromosomal DNA during the isolation procedure, the following tests were made. First, smears of isolated nucleoli were hydrolysed in N hydrochloric acid at 60° C for 12 min and immersed in Feulgen reagent for 2 h. In a few cases, small Feulgen-stained bodies (similar to those described as nucleolar organizers[23]) could be seen attached to the nucleoli. However, the dimensions and frequency of occurrence of these suggested that they would account for less than 0·1 per cent of the nucleolar DNA found. Apart from these bodies, the nucleoli were found to have no detectable stain whereas isolated nuclei treated in the same way had approximately the same amount of stain as nuclei in intact control roots which were formaldehyde-fixed, hydrolysed and stained concurrently. Since it could be argued that the absence of staining was due to leaching out of the DNA during the Feulgen procedure, another test was made. Isolated nucleoli were first subjected to the Feulgen procedure, then washed in ice-cold 0·2 N perchloric acid and finally hydrolysed in N perchloric acid at 75° for 30 min. Both the hydrochloric acid and the perchloric acid were then examined for the presence of DNA. In four experiments of this type it was found that between 25 and 50 per cent of the nucleolar DNA was being lost in the Feulgen procedure. In each case the rest could be recovered in the perchloric acid. It seems clear, therefore, that after the Feulgen procedure DNA is still present in the nucleoli. The fact that it is suggest that this was not due to the presence of a contaminant.

Two further tests for contamination were made. In the first, excised root-tips were immersed for 6 h in Knop's solution containing tritiated thymidine (1 μc./ml.). Nuclei and nucleoli were then isolated and smeared on separate slides. Autoradiographs were prepared and the average number of grains over nuclei compared with the average number over nucleoli. As can be seen from Table 3, the amount of nucleolar label (allowing for an average of 1·52 nucleoli per nucleus) is approximately 2·5 per cent of the nuclear. Had all the nucleolar DNA been derived from the chromosomes during the isolation procedure, a figure of about 17 per cent would have been expected. Unfortunately, sections could not be used for this comparison because the nucleoli, when centrifuged into pellets for the purpose of embedding, clumped and lost their separate identity. However, from interferometric measurements of optical path differences in media of known refractive index, the maximum thickness of nuclei and nucleoli in the autoradiographs was calculated to be 0·95μ and 0·33μ respectively. It is clear, therefore, that a correction for self-absorption can only accentuate the differences shown in Table 3.

In the final test for contamination, excised root-tips were again labelled for 6 h, this time using ^{14}C-thymidine. Nuclei and nucleoli were then isolated and DNA extracted from both. Known quantities of the two DNA fractions were then dried down on glass coverslips and the specific activities determined using a thin end-window counter. Again, had all the nucleolar DNA been derived from the chromosomes during the isolation procedure, the specific activities of the two fractions would have been the same. In fact, as Table 4 shows, the nucleolar fraction had approximately 10 per cent of the specific activity of the nuclear fraction. This is compatible with the autoradiographic results and suggests that at least 90 per cent of the DNA found in nucleoli cannot be accounted for by contamination unless, as seems unlikely, contamination by unlabelled chromosomal DNA occurs. The absence of Feulgen stain seems to rule this out. The relatively small amount of incorporation into nucleolar DNA, found in the above experiments, suggests that the material for this component might be drawn from a pool other than that involved in the synthesis of chromosomal DNA. Alternatively it could be derived from the chromosomal DNA itself at a time other than that covered by the period of labelling.

The technique described for the isolation of nucleoli from *V. faba* roots has been applied successfully in several other species of plants: *Pisum sativum*, *Phaseolus vulgaris*, *Allium cepa*, *A. ampeloprasum*, *A. babingtonii*, *Tradescantia ohioensis* and *Zea mays*. Nucleolar DNA has been found in all of them. Although comparatively few determinations of nucleic acid content in this material

have so far been made, it appears that the proportion of nuclear DNA which is in the nucleoli is always of the same order as that found in *V. faba*. The presence of such a fraction of DNA, which is Feulgen-negative, may seem to cast doubt on the validity of Feulgen microphotometry as a method for estimating total DNA content. However, if there proves to be little variation between species in the magnitude of the nucleolar DNA fraction, its presence need not be a serious source of error. The correlations which have been found between absolute amounts of DNA and the amounts of Feulgen stain[24,25] seem to provide confirmation of this.

If it is accepted that DNA is an integral part of nucleolar structure, the results of several previous experiments may be open to new interpretation. Perhaps the most relevant are those which have been concerned with the synthesis of nucleolar RNA.

The nucleolus is known to contain RNA with a high rate of turnover[26–28] and, furthermore, there is evidence to suggest that the synthesis of this RNA is DNA-dependent since it can be inhibited by both actinomycin *D*[29–31] and DNase[31]. Sirlin *et al.*[29] have suggested that nucleolar RNA synthesis is primed by 'messenger' RNA which is made on the chromosomal DNA and then moves to the nucleolus. But if the nucleolus itself contains DNA as well as RNA, possibly in a 2 : 1 relationship as the above results and those of Rees *et al.*[9] suggest, it would seem unnecessary to postulate the formation of an extrinsic 'messenger'. In any event, the autoradiographic evidence[32] for the movement of RNA from chromosomes to nucleolus has been seriously challenged[33] on the grounds that it fails to take into account the role of precursor pools as well as some fundamental differences between the nucleolus and the rest of the nucleus. These include differences in base composition[27,34,35], differences in concentration[6,8,16–19], and differences in the distribution of radioactivity according to the precursors used[33,36]. A continuation of such investigations into the chemical and physical nature of the components of nucleoli in different types of cells and environments is required before the true functions of these organelles can be elucidated.

BINDING OF PROFLAVINE TO DEOXYRIBONUCLEIC ACID AND RIBONUCLEIC ACID AND ITS BIOLOGICAL SIGNIFICANCE

By Dr. CHRISTOPH SCHOLTISSEK* and Prof. RUDOLF ROTT*

Max-Planck-Institut für Virusforschung, Tübingen

IT has already been shown that proflavine inhibits DNA-dependent RNA synthesis in a way similar to actinomycin[1]. It binds to DNA[2] and leads to mutations[3,4]. Furthermore, it destroys the infectivity of several viruses in the presence of light[5] and interferes with virus multiplication[6]. Nevertheless, the suppression of RNA synthesis *in vivo* is not complete, and the RNA synthesized in the presence of proflavine shows some peculiarities in base composition and base sequence[7].

This article is concerned with the action of proflavine on DNA and RNA. We have shown that proflavine which has little effect on energy metabolism not only inhibits RNA synthesis but also prevents the production of protein. Proflavine binds not only to DNA, but also to RNA. Furthermore, it interferes with the multiplication of fowl plague virus as well as with Newcastle disease virus (NDV). This is in contrast to actinomycin, which binds only to DNA[8,9], does not affect protein synthesis immediately[10,11], and does not interfere with the multiplication of NDV[12,13]. The results suggest that proflavine inhibits multiplication of fowl plague virus in a similar way to actinomycin, while it inhibits NDV formation by reaction with an RNA template.

Chick fibroblast cultures, prepared according to Kraus and Schäfer[14], were used throughout. The changes in incorporation of isotopic precursors of RNA and protein synthesis, after transferring from growth to minimal medium, are described in refs. 7 and 11.

The 'Rostock' strain of fowl plague virus and the 'Italien' strain of NDV were used. The cell layers were infected with a multiplicity of about 100 as described elsewhere[15].

* Present address: Institut für Virologie, Giessen, Germany.

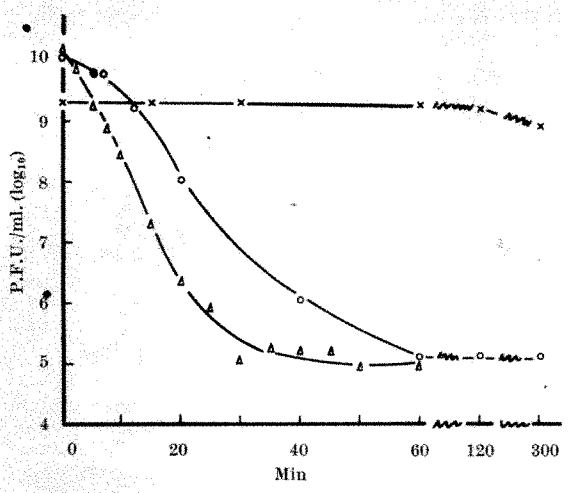

Fig. 1. Inactivation of NDV in the presence of proflavine with monochromatic light at different wave-lengths. NDV in sodium chloride-phosphate buffer *p*H 7·2 containing 50 μg/ml. proflavine was exposed for different lengths of time (abscissa) to monochromatic light of three different wave-lengths. As light source a Zeiss-spectrophotometer *PMQ* II with the fluorescence equipment *ZFM* 4 was used. The ratio of the energy at 365 mμ (○), 436 mμ (*Δ*) and 546 mμ (×) as measured by a thermo-element was 1/1/2·3; the ratio of the absorption at these wave-lengths was 0·11/1/0·006

The infectivity was determined by the plaque test[15]. The hæmagglutination titre was estimated in the usual manner (for fowl plague virus at room temperature, for NDV at 4° C). The microcomplement-fixation test[16] as modified by Hennessen[17] was used. *Q* is the ratio of the amount of complement causing 50 per cent hæmolysis with antiserum to that with normal serum. In the case of fowl plague virus only the synthesis of the RNP antigen (*s*-antigen) is measured by the complement-fixation test[18], while in the case of NDV, convalescent antiserum from hamsters, which reacts with all virus components, was used[19]. The neuraminidase activity was determined according to Aminoff[20], using *N*-acetylneuraminic acid as substrate.

The synthesis of RNA was measured by the incorporation of ^{14}C-uridine (1 mc./8·6 mg) into the acid-insoluble fraction, protein synthesis by the incorporation of ^{14}C-leucine (6·5 μc./μM L-leucine, dilutedby 1 μM/ml. ^{12}C-D,L-leucine). The procedures were described in detail in ref. 21.

Proflavine (free base) was a gift from the Bayerwerke, Leverkusen, Germany. Actinomycin *D* was a gift from Merck, Sharp and Dohme, New York. ^{14}C-Leucine was obtained from the Radiochemical Centre, Amersham, England. ^{14}C-Uridine was purchased from the New England Nuclear Corporation, Boston, U.S.A. The highly polymerized calf thymus DNA (type II) and the low-molecular-weight DNA from herring sperm (type IV) was obtained from Sigma Chemical Co., St. Louis, Missouri. The high-molecular-weight RNA was isolated from rat liver microsomes by phenol. The radioactivity was determined in a windowless flow counter model *FH* 516 (Frieseke and Hoepfner, Erlangen-Bruck, Germany).

(1) *Inactivation of fowl plague virus and NDV with proflavine in the presence of light.* It has been shown by Franklin[6] that proflavine inhibits the synthesis of fowl plague virus. Since we were unable to repeat his results in a consistent manner, we tested the influence of proflavine on the isolated virus. NDV and fowl plague virus were found to be inactivated by proflavine only in the presence of light. Both viruses were inactivated most rapidly with a wave-length close to the adsorption maximum of proflavine (436 mμ) (shown for NDV in Fig. 1). The hæmagglutination titre and the complement-fixing activity were not affected by this treatment. However, neither of the viruses was inactivated completely (Fig. 1). A second addition of proflavine at a time when the inactivation curve had levelled off had no further effect. Inoculation of the residual virus isolated from single plaques into embryonated eggs again led to the formation of proflavine-sensitive virus particles. Therefore there is no selection of a resistant mutant, and the formation of a proflavine-resistant fraction is not yet understood. Similar results were obtained with fowl plague virus, although the results are not so clear as those with NDV due to multiplicity reactivation[21].

(2) *Inhibition of fowl plague virus and NDV-multiplication by proflavine.* Since our results on the inhibition of fowl plague virus multiplication were not consistent when working in the presence of daylight, we compared the inhibition of both viruses by proflavine in red light and in normal light. Normal light means that the proflavine cultures received a light pulse of 15 min immediately after infection. Thereafter they were incubated in the dark. All further tests were performed in red light. Fig. 2 shows that the inhibition of fowl plague virus multiplication is much more pronounced if a light pulse is given immediately after infection. The same holds for NDV (not shown here). Nevertheless, there is a marked difference between the dose of proflavine needed to get a comparable inhibition of NDV and fowl plague (Fig. 3). Working in red light, considerably more proflavine was needed for the inhibition of the multiplication of NDV than for fowl plague virus.

In Fig. 2 it can be seen that, after a light pulse, the yields of the different virus components of fowl plague virus are affected to different extents by proflavine. The hæmagglutinin titre and neuraminidase activity do not go down in parallel with the infectivity, while the RNP antigen titre is unaffected by even relatively high doses of proflavine. Similar results have been obtained recently by the use of other inactivating agents on the isolated virus particles[21,22]. Therefore the best explanation for this phenomenon, and for Franklin's findings[6], is a partial inactivation of the virus genome of the fowl plague virus in the presence of proflavine and light. In the case of NDV, no differential effect on the production of the various virus components has been observed, except for a delay in the fall in the complement-fixing activity of little significance. Chemicals reacting specifically with the nucleic acids were

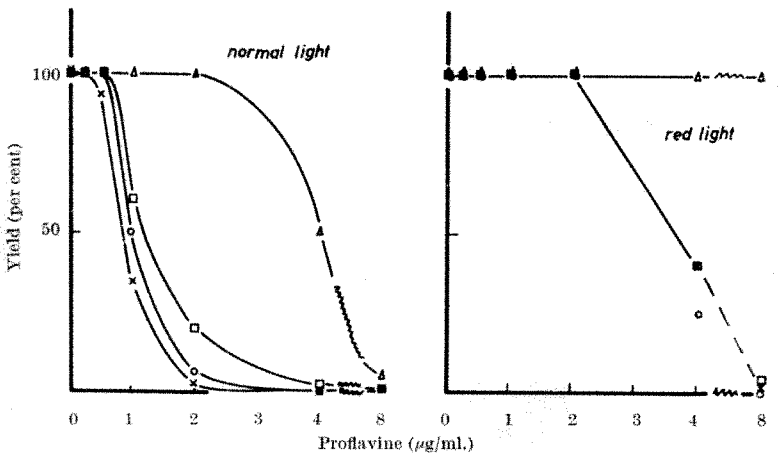

Fig. 2. Dose effect of proflavine on the formation of fowl plague components in tissue cultures after a light pulse (left) and working in red light (right). After infection and the addition of different doses of proflavine the cultures were exposed for 15 min to the light of three Philips lamps (*TL* 20 W, 34 D) at a distance of 30 cm or to red light, respectively. ×, plaque-forming units (P.F.U.), ○, hæmagglutination titre; □, neuraminidase activity, △, RNP antigen titre

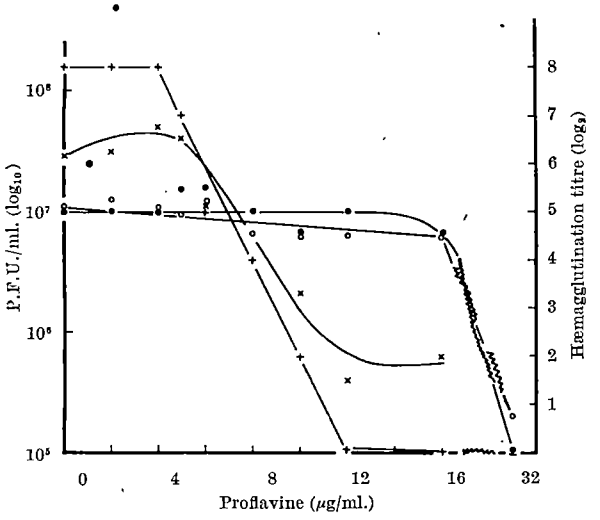

Fig. 3. Comparison of the effect of different doses of proflavine on the inhibition of fowl plague virus and NDV multiplication. Different doses of proflavine (abscissa) were added to NDV and fowl plague-infected tissue cultures in red light. The cells were gathered 8 h post-infection and the virus titre determined after the disruption of the cells. ×, P.F.U., +, hæmagglutinin, fowl plague; ○, P.F.U., ●, hæmagglutinin, NDV

also found to inhibit the ability to synthesize all the various components of NDV at the same rate[21].

When working in red light, no significant differential effect on the formation of the various virus components of fowl plague virus was observed, except for a greater resistance to proflavine of the RNP antigen formation (Fig. 2).

It has been shown that cellular RNA synthesis cannot be suppressed completely by proflavine[7]. Therefore a residual synthesis of viral RNA might proceed even in the presence of moderate doses of proflavine. This residual viral RNA might be enough to serve as template for RNP antigen protein synthesis, but not for that of other viral proteins. A similar effect has been observed when actinomycin, which inhibits the formation of fowl plague RNA, is added 2 h post-infection to fowl plague-infected tissue cultures. At this time only very low amounts of viral RNA are present in the infected cells, but this RNA gives rise, at a diminished rate, to normal yields of RNP antigen, without the formation of significant amounts of hæmagglutinin[23]. The RNP antigen could be labelled under these conditions with ^{14}C-leucine, but only very little with ^{14}C-uridine, suggesting that it contains little RNA (unpublished results). No RNP antigen was formed if actinomycin was added immediately after infection.

(3) *Binding of proflavine to DNA and RNA.* The binding of actinomycin to DNA is accompanied by a specific shift in the absorption spectrum of the chromophoric group of the antibiotic[8,24]. Since the absorption spectrum of proflavine also can be altered by nucleic acids (Häbich and Burberg, personal communication), this change has been selected as a quantitative test for the binding of proflavine by nucleic acids from different sources. At high concentrations of nucleic acid, the absorption maximim of proflavine shifts from 445 mμ to 460 mμ. Therefore the ratio of the absorption at 445 mμ to that at 460 mμ was determined as a function of the concentration of the nucleic acids. It can be seen in Fig. 4 that about three times more RNA or degraded DNA is needed than high molecular weight DNA, in order to get a comparable shift in the absorption spectrum of proflavine. This suggests that high-molecular-weight DNA (double stranded) binds proflavine about three times as well as single-stranded RNA, with a molecular weight of about one million. This is in contrast to actinomycin, which binds only to DNA. In order to get a comparable effect of RNA by actinomycin, at least 100 times more RNA is needed[24].

(4) *Inhibition of RNA and protein synthesis by proflavine.* Proflavine inhibits the incorporation of ^{14}C-uridine into the acid-insoluble fraction of the cell. But even with very high concentrations of this compound there is always a residual incorporation of the isotope of about 4 per cent[7].

The effect of proflavine on RNA synthesis was compared with that on protein synthesis. Fig. 5 shows that with low amounts of proflavine (2 μg/ml.) there is a small stimulation of the incorporation of ^{14}C-uridine, while the incorporation of ^{14}C-leucine is slightly depressed. Another difference has been observed with high concentrations of proflavine. While the incorporation of ^{14}C-uridine levels off at about 25–50 μg/ml. proflavine, that of ^{14}C-leucine drops further to an insignificant amount. But from the values between these extremes it can be seen that between two and three times more proflavine is needed for the inhibition of protein synthesis than for the inhibition of RNA synthesis. The inhibition of synthesis of both RNA and protein starts immediately after the addition of the drug (Fig. 6). The incorporation of precursors of RNA and protein in the presence of proflavine rises linearly with time. Therefore a destruction of the templates for synthesis of RNA and protein, respectively, during the experiment can be excluded.

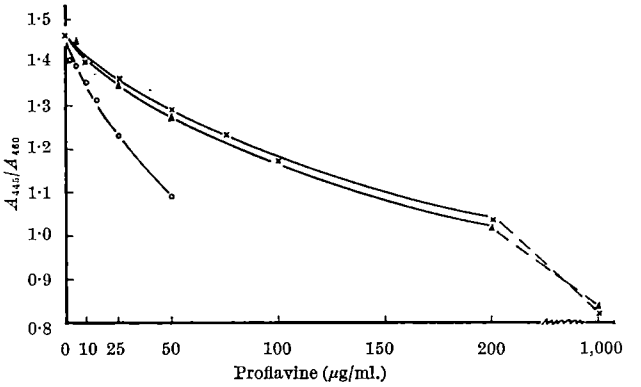

Fig. 4. Shift in the absorption maximum of proflavine by different doses of DNA and RNA. 10 μg/ml. proflavine in NaCl-phosphate buffer *p*H 7·2 was mixed 1 : 1 with solutions of different concentrations of nucleic acids and the absorption was measured at 445 mμ and 460 mμ. ×, rat liver microsomal RNA; ○, thymus DNA (high molecular weight); △, herring sperm DNA (low molecular weight)

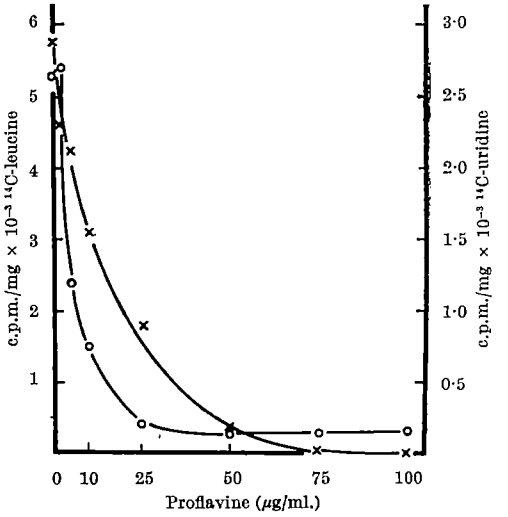

Fig. 5. Inhibition of synthesis of RNA and protein by proflavine. For each point one culture received 0·13 μc. ^{14}C-leucine or 0·2 μc. ^{14}C-uridine, respectively, and the corresponding dose of proflavine. The values are expressed as c.p.m./mg dry wt. ○, ^{14}C-leucine; ×, ^{14}C-uridine

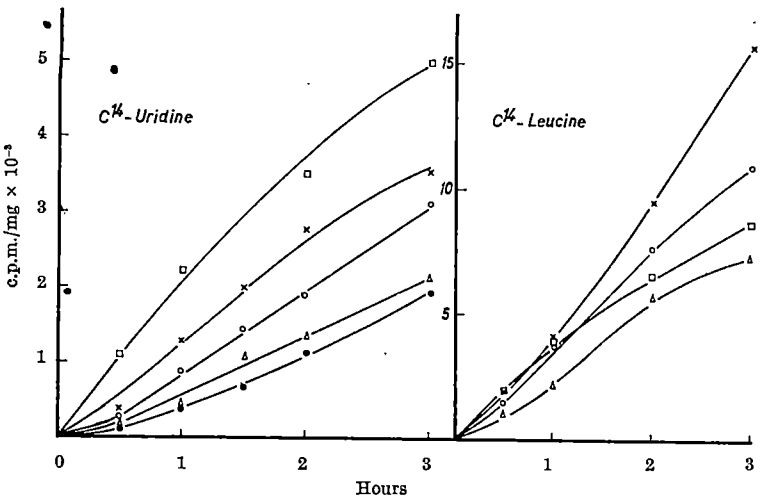

Fig. 6. Influence of a light pulse in the presence of proflavine on the synthesis of RNA and protein. For each point one culture received 25 μg/ml. proflavine and 0·13 μc. ^{14}C-leucine or 0·2 μc. ^{14}C-uridine, respectively. The cultures were exposed for different lengths of time to three Philips lamps (*TL* 20 W, 34 D) at a distance of 30 cm or kept in red light, respectively, before the isotope was added. Thereafter they were incubated in the dark for different lengths of time (abscissa). Left: ^{14}C-uridine: ×, red light; ○, 5 min light; △, 8 min light; ●, 11 min light; □, control without proflavine; the values for the controls have to be multiplied by 10. Right: ^{14}C-leucine: ×, red light; ○, 5 min light; △, 10 min light; □, control without proflavine; the values for the controls have to be multiplied by 3

All these experiments were performed with red light. Next we tested the influence of a pulse of normal light on the synthesis of RNA and protein in the presence of proflavine. In these experiments the tissue cultures were left in the light for different lengths of time immediately after addition of proflavine, then the isotope was added and the cells incubated in the dark. Fig. 6 shows the results of a series of experiments with different pulse-lengths. It can be seen that there is greater inhibition of RNA synthesis if the cultures received a light pulse in the presence of proflavine. But the effect of light on the RNA synthesis is much less pronounced than that on the production of infectious virus. Fig. 6 shows also that protein synthesis in the presence of proflavine can be influenced by a light pulse to about the same degree as RNA synthesis.

(5) *Action of proflavine on the energy metabolism of the cell.* The inhibition of RNA synthesis as well as protein synthesis by proflavine raises the question whether or not this inhibition is due to the breakdown of the energy production. Substances which interfere with energy metabolism also inhibit the production of the energy-rich phosphate compounds. Therefore the extent to which proflavine effects the formation of the 5′-uridine phosphates was tested. ^{14}C-Uridine was added to tissue cultures treated with different doses of proflavine. The results of one experiment are shown in Fig. 7. Proflavine has very little effect on the production of the 5′-uridine phosphates. Even as much as 75 μg/ml. proflavine did not inhibit the formation of UTP more than 30 per cent. Therefore a disturbance of the energy metabolism by proflavine can be excluded as an explanation for the inhibition of synthesis of RNA and protein.

The results presented here have demonstrated that synthesis of RNA as well as of protein can be inhibited by proflavine. To inhibit protein synthesis to the same extent as RNA synthesis, between two and three times as much proflavine is needed. This is in contrast to the action of actinomycin, which does not affect the protein synthesis immediately after its addition. The drop in the protein metabolism which is observed later is probably due to an exhaustion of the messenger RNA, rather than to a direct inhibition of protein synthesis by actinomycin.

Another difference between actinomycin and proflavine can be seen in the binding of these compounds to high-molecular-weight DNA and RNA. While actinomycin attaches only to DNA, proflavine binds to both DNA and RNA. But here again a factor of three is involved; three times more RNA is needed in order to get an effect comparable with that on DNA.

It is known that actinomycin inhibits the multiplication of the influenza viruses, of which fowl plague is a member, but not the production of NDV[12,13]. Two to three times more proflavine is needed for the inhibition of NDV multiplication than for the inhibition of the formation of fowl plague virus. Therefore it is suggested that proflavine prevents the formation of fowl plague virus by acting in the same way as actinomycin. In addition, proflavine inhibits the multiplication of NDV probably by binding to RNA and consequently preventing the synthesis of NDV proteins.

Since the production of the 5′-uridine phosphates, and consequently the energy metabolism, is not significantly affected by proflavine, we suggest that this compound acts on DNA as well as on RNA, preventing RNA and protein synthesis, respectively. Whether, or to what extent, binding of proflavine to soluble RNA is involved in the inhibition of protein synthesis is not yet known.

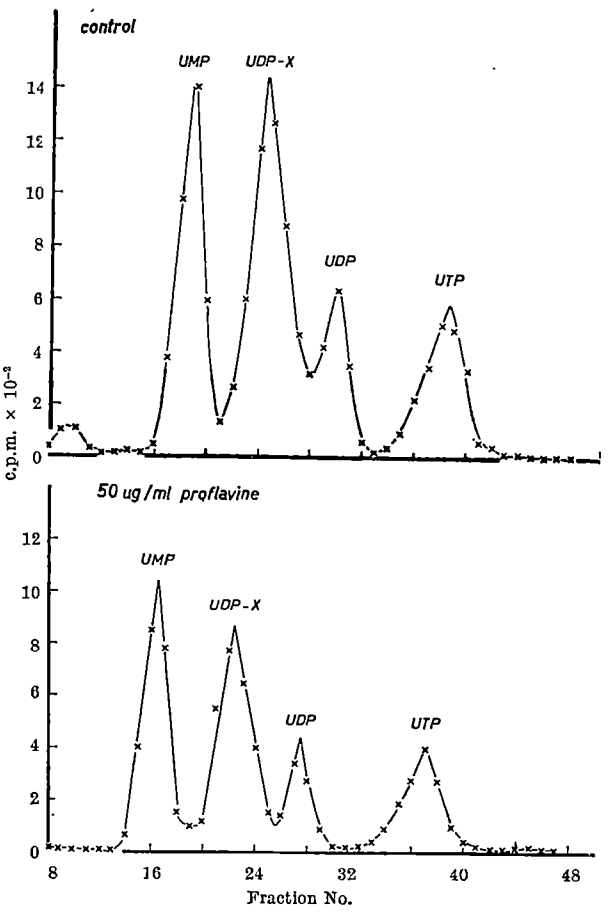

Fig. 7. Effect of proflavine on the formation of the 5′-uridine-phosphates. Five cultures, treated with 50 μg/ml. proflavine, and five controls received 1 μc. ^{14}C-uridine per culture in red light. 1 h later the cells were gathered and precipitated with cold perchloric acid (0·4 N final concentration). 1 mg 5′-UMP and 2 mg 5′-UTP (containing some 5′-UDP) were added to the supernatant. After neutralization with $KHCO_3$ and removal of the $KClO_4$ in the cold the supernatant was chromatographed on a 'Dowex 1 × 2'-column with ammonium formate according to Hurlbert *et al.* (ref. 25). UDP-*X*, 5′-uridine-diphosphate with a carbohydrate bound to the phosphate group

EFFECTS OF NITROGEN, AND OF RESPIRATORY INHIBITORS, ON ETHYLENE PRODUCTION BY A SUB-CELLULAR FRACTION FROM TOMATOES

By M. MEHERIUK and PROF. MARY SPENCER
Departments of Plant Science and Biochemistry, University of Alberta, Edmonton, Canada

NUMEROUS experiments with whole fruit and tissue slices have indicated the existence of a relationship between respiration and ethylene production[1]. This article deals with an investigation of the effects of an atmosphere of nitrogen, and of various inhibitors, on ethylene production by a sub-cellular system from ripening tomatoes.

Preparation of the sub-cellular particles (separated at 35,000 *g* for 15 min), their sonication; and the methods for collection, identification, and measurement of ethylene have been described previously[2,3]. When nitrogen was substituted for air, no consistent effect was observed on the initial evolution of ethylene (Table 1), possibly because of remaining traces of air, or the presence of preformed ethylene or ethylene precursors. Production thereafter was less in nitrogen than in air (runs 1, 2, 3*A* and *B*). However, if the samples under nitrogen were returned to air, ethylene production was greater than in the air controls (run 5). Addition of ATP to the samples in a nitrogen atmosphere also resulted in an ethylene production greater than that of the air controls (runs 3 and 4).

The results from these experiments with sub-cellular fractions from tomatoes are similar to those obtained with whole fruits by Hansen[4] and with apple tissue disks by Burg and Thimann[5]. The latter authors concluded that, in nitrogen, a precursor accumulated that could be rapidly oxidized on exposure to air, and then converted to ethylene. Our results indicate that, with the sub-cellular fraction from tomatoes, ATP may substitute for readmission of oxygen in the production of ethylene.

Several enzyme inhibitors were used to investigate the mode of ethylene production by the sub-cellular fraction from tomatoes. Effects on both the initial evolution of ethylene (during the first 3 h) and that produced after overnight ageing of the particles were observed, as the factors controlling production in these two cases appear to be different[6,7]. Results of the inhibitor experiments are presented in Table 2.

Cyanide at concentrations of 1 or 2×10^{-4} M did not inhibit ethylene evolution by the sub-cellular fraction (runs 1–4). When the cyanide was increased to 1×10^{-2} M, the initial production was not inhibited, but there was distinct reduction in ethylene evolved by aged, resonicated particles (runs 5 and 6). (No change in *p*H occurred in the particulate suspension.) These results are similar to those obtained by Hansen[4], with pears, and Gibson[8], with *Penicillium digitatum*, but Burg[9] found "no obvious effect on ethylene production" by apple disks treated with 10^{-2} M cyanide.

It should be noted that the sub-cellular particles were suspended in sucrose-phosphate buffer containing ATP, and the energy supply may not therefore have been limiting in the initial production of ethylene. Production of high-energy compounds may also have occurred through a cyanide-insensitive electron transport system known to be present in many plant tissues[10]. On the other hand, lack of inhibition by cyanide may reflect the presence of an excess of cytochrome oxidase, or the conversion of cyanide into other compounds[11].

Since cyanide in sufficient concentration did inhibit, to a considerable extent, the ethylene production of the aged and resonicated suspension, the possibility remains that metal-containing enzyme systems, or enzymes requiring carbonyl or disulphide groups for their activity, or cyanohydrin-forming metabolites such as pyruvate and oxaloacetate, are involved, directly or indirectly, in ethylene production. The lack of cyanide inhibition of the initial (1–2 h) ethylene production, even at 10^{-2} M potassium cyanide concentration, could be due to several factors in addition to those mentioned above: the ethylene precursor (or precursors), the new formation of which would be prevented by cyanide, initially may have been present in the preparation in such amounts that it was not the rate-limiting factor in ethylene production; alternatively, preformed ethylene may have been bound by some factor, and liberated on addition of cyanide. Liberation of preformed ethylene would mask inhibition of formation of new ethylene.

Malonate (10^{-2} M) had no pronounced effect on ethylene evolution (runs 7 and 8). Gibson[8] observed that the same concentration of malonate (10^{-2} M) produced a 13 per cent inhibition of ethylene production by *Penicillium digitatum*, but did not affect the respiration. The lack of effect of malonate on the tomato particles does not necessarily exclude a role for the Krebs tricarboxylic acid cycle in ethylene production. Malonate can be readily metabolized by plants and malonate inhibition in plant tissues is usually found only when the concentration of malonate is relatively high, and the medium is acid, and even then it may take some time to develop[10].

Monofluoracetate, like malonate, did not appreciably inhibit ethylene production (runs 9 and 10), but it is possible that higher concentrations of the inhibitor would have an effect[8,12].

Reaction mixture as in Table 1. *A* and *B* are two halves of the same particulate preparation, *A* being the control and *B* the sample treated with inhibitor. ATP ($1{\cdot}98 \times 10^{-3}$ M) was added after the initial sonication. Sonications were performed and ethylene collections were made at the same time intervals as in Table 1, and the appropriate results added to give the above figures. When values were expressed on a nitrogen basis, about the same comparative activities were obtained. *T*, trace.
* Glutathione (1×10^{-2} M) added after 1 h.

Arsenite at a concentration of 10^{-1} M almost completely inhibited the production of ethylene by aged particles on sonication (runs 11 and 12). At 10^{-4} M, where it could be considered to act more selectively to inhibit oxidative decarboxylation of keto acids, it only slightly inhibited the production after overnight ageing (runs 13 and 14). At both concentrations, the initial production of the gas was greater in the presence of the inhibitor.

Treatment of the sub-cellular fraction from tomatoes with 1×10^{-2} M iodoacetamide resulted in pronounced inhibition of the ethylene production by the aged and resonicated fraction (runs 15 and 16). Similar results were reported by Burg and Thimann[12], with apple tissue disks, and Gibson[8], with *Penicillium digitatum*.

When *p*-chloromercuribenzoate (*p*-CMB, 1×10^{-4} M) was used with the sub-cellular particles, ethylene production was decreased (runs 17 and 18). Glutathione (1×10^{-2} M) reversed this effect (runs 19 and 20). The protective function of glutathione with respect to sulphydryl groups is well known. (Sonication of glutathione itself in the reaction mixture (without particles) did not result in detectable ethylene production. When glutathione was added to particles suspended in the usual reaction mixture, there was no increase in ethylene evolution over the controls.)

Sodium fluoride (1×10^{-2} M), in the presence of ATP, had little effect on ethylene production by the sub-cellular fraction from tomatoes (runs 21 and 22). This is similar to the results of Burg and Thimann[12], who found that fluoride inhibition of ethylene production by apple tissue disks was reversed by addition of ATP. Succinic acid dehydrogenase, phosphatases, pyrophosphatases and a number of glycolytic enzymes, are among those inhibited by fluoride. Negative results with inhibitors do not, of course, preclude participation of a reaction in the biosynthesis of a compound, for the product of the inhibited reaction may already be present in sufficient amounts in the enzyme preparation.

Although the results of experiments with any single inhibitor cannot be accepted as a conclusive test of the operation of a pathway, the summation of evidence from experiments with several inhibitors can be a useful guide. The first observation that may be made is that the effects of inhibitors on the initial ethylene evolution and on the evolution of aged and resonicated particles were often different, which indicated once more that different mechanisms might be involved. (It is for this reason that figures for total ethylene production over the 24-h period have not been included, their significance being doubtful.) Preformation and binding of the gas as factors in the initial production of ethylene appear possible, and participation of non-enzymatic reactions in this evolution has been suggested previously[6,7].

With respect to the aged and resonicated particles, operation of the complete TCA cycle would not appear to be a necessity for ethylene evolution. (Monofluoracetate (10^{-3} M), arsenite (10^{-4} M), malonate (10^{-2} M) and cyanide (2×10^{-4} M) did not significantly hinder ethylene production.) The fact that higher concentrations of cyanide (1×10^{-2} M) and arsenite (10^{-1} M) did inhibit evolution of the gas would not necessarily mean that the TCA cycle was involved, for at these concentrations many enzyme systems in addition to those directly concerned with the TCA cycle are likely to be affected[13]. Burg and

Thimann[5] concluded that the TCA cycle was not involved in ethylene production by apple tissue disks, and Gibson[8] found that pyruvate was a better ethylene precursor than fumarate or succinate, in *Penicillium digitatum*. On the other hand, Wang *et al.*[14], who used long collection periods for ethylene, concluded that there was an intimate connexion in *Penicillium digitatum* between production of the gas and the Krebs tricarboxylic acid cycle.

Involvement of essential sulphydryl groups in ethylene production by the sub-cellular particles was indicated by experiments with *p*-CMB and glutathione, as well as those with iodoacetamide. Thiol reagents can inhibit plant respiration by interfering with glycolysis, the hexose monophosphate pathway, and organic acid oxidation[15].

The inhibitors may exert their effects at any stage in the pathway of ethylene synthesis. The general pattern of inhibition of the production of the gas by aged, resonicated particles indicates that enzymatic reactions are involved. However, they may effect the production of a precursor of the gas, rather than the final evolution of ethylene itself.

INHIBITION OF PROTEIN SYNTHESIS BY ACRIDINE ORANGE

By Dr. A. V. ZELENIN and Mrs. E. A. LIAPUNOVA

Institute of Radiation and Physico-chemical Biology, Academy of Sciences of the U.S.S.R., Moscow

THE interaction of acridine diamino derivatives with nucleic acids has been extensively investigated, particularly *in vitro*[1–5]. It is not yet known, however, how these substances affect the synthesis of protein.

We have examined this problem autoradiographically having chosen as an active substance acridine orange (2,8-*bis*dimethylaminoacridine) the effect on protein synthesis of which has been to some extent reported in the literature[6]. Preparations of 1–2 days monolayer cultures of amnion cells (strain *FL*) were placed for various times (3 min–48 h) in a medium with acridine orange (AO) in a 0·1–6·0 μg/ml. concentration. During the test, precautions were taken not to expose the cells to the action of light. After treatment with AO the excess dye was washed off from the slides, the latter being then placed in a fresh medium containing ^{35}S-methionine or ^{14}C-phenylalanine (3–5 μc./ml.), fixed in 70 per cent ethanol for 3–5 min and treated for 5 min with a 5 per cent solution of perchloric acid at 0°–2° C. The autoradiograms were prepared using *NJKFJ* dipping emulsions. Quantitative results characteristic of the intensity of the incorporation of the tracers were estimated by counting the number of silver grains per 1 cell or per field of standard size, fully covered by the cells.

The first series of experiments have shown the treatment of cells by relatively high doses of AO (6 μg/ml.) for 16–20 h to suppress fully the incorporation of labelled precursors. Subsequent experiments have led to the conclusion that the incorporation of tracers is partly inhibited when cells are treated with AO in a concentration of 0·5–1·0 μg/ml. AO practically inhibits protein synthesis already at a concentration of 1·5–2·0 μg/ml. (Table 1).

It has been further shown that the incorporation of a tracer is already markedly inhibited 10–15 min after the beginning of treatment of cells with AO (Table 2).

Some differences in the results of various runs seem to be due to the different conditions of cells.

Our experiments have thus shown that AO markedly affects protein synthesis and practically inhibits it several minutes after the beginning of its action. The activity of the compound is in this respect strong enough, being 1–2 μg/ml. In complete accordance with the inhibition of protein synthesis is the suppression of mitotic activity of cultures by AO. This suggests that the well-known antimitotic effect of AO and some other diaminoacridines[7,8] is due to their inhibiting action on protein synthesis.

It proved of interest to elucidate the ways in which AO influences protein synthesis. It seemed most reasonable that the effect of AO should be connected with the inhibition of the synthesis of the messenger-RNA. It was found, however, that actinomycin *D* (which completely hinders the synthesis of cell RNA, estimated by the incorporation of ^{3}H-uridine) even after 6–10 h of its action affect protein synthesis only by 60–70 per cent[9]), whereas treatment with AO suppresses the incorporation of radioactive tracer into the protein in 15 min after the beginning of the experiment. The supposition that the action of AO on protein synthesis is effected through the inhibition of RNA synthesis is also contradicted by the direct autoradiographic observation on the incorporation of ^{3}H-uridine and ^{3}H-thymidine into AO-treated cells (Table 3).

One can see from Table 3 that even after 48 h of AO treatment the rate of synthesis of RNA is reduced only to 75 per cent, this result being in agreement with the results obtained by Brown and Stewart[10], who showed that proflavine inhibited the synthesis of the protein part

Table 1. Effect of Different AO Concentrations during 20 h on the Incorporation of Labelled Amino-acids into the Cells

of foot-and-mouth virus without any marked influence on the synthesis of its RNA.

It is necessary also to mention that AO does not affect primarily either the cell respiration[6,11] or oxidative phosphorylation. The latter fact follows from our experiments (Table 3) in which the possibility of normal undergoing of phosphorylation of ^{3}H-thymidine and ^{3}H-uridine molecules in AO-treated cells was shown.

It seems most probable that inhibition of the protein synthesis by AO takes place in the early stages of proteosynthesis and is connected with the inactivation of *s*-RNA by AO (ref. 5). On the other hand, AO (as follows from the data presented in Table 3) produces some inhibitory effect also on the synthesis of DNA and RNA. This effect takes place in a rather short period of time after the beginning of AO action and seems not to be connected with inhibition of protein synthesis but due to the direct interaction of AO with DNA, possibly by intercalation between its double helix molecule[3,4].

MUTAGENICITY OF IONIC POLYMERS AND LEUKÆMOGENIC VIRUSES RELATIVE TO NUCLEIC ACIDS IN *Drosophila melanogaster*

By Dr. O. G. FAHMY and Dr. MYRTLE J. FAHMY

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

THE mutagenic activity of macromolecules was first discovered for deoxyribonucleic acid[1] (DNA), but was later ascertained for other cellular constituents[2]—such as ribonucleic acid (RNA), deoxyribonucleoproteins (DNP) and histones. These various molecules shared the property of being predominantly effective in the induction of small deletions resulting in the *Minute* phenotype, although their efficiency in this respect varied considerably. This indicated some degree of non-specificity as regards the molecular structure of the inducing agent and suggested that synthetic polymers might also be active, especially if they were somewhat imitative of the hereditary macromolecules. More interesting, from the point of view of the mechanism of carcinogenesis, is the question whether viruses—which might be looked on as infective nucleoproteins—also possess the macromolecular type of mutagenesis. In an attempt to probe these possibilities, mutagenic tests were undertaken with various synthetic polymers simulating natural macromolecules, as well as with cell-free extracts from normal and leukæmic mice (with Gross and Moloney viruses).

The synthetic polymers tested belonged to the following chemical series: (1) polyelectrolytes, represented by polymethacrylic acid (mol. wt. $\simeq 10^6$) used as the sodium salt; (2) polyamino-acids, represented by polyglutamic acid (mol. wt. $\simeq$40,000); (3) polynucleotides, polyadenylic acid (polyA) as a representative of a purine polymer and polyuridylic–cytidylic acid (poly-UC; 3U : 1C—kindly supplied by Prof. S. Ochoa, New York University Medical Centre), as a representative of pyrimidine polymers (both of low molecular weight; of the order of 20,000).

The cell-free extracts were derived from mouse tissues, which were either normal or leukæmic and were intended for the assessment of the change of mutagenicity in the presence of the leukæmogenic viruses (both of Gross and Moloney). In the Gross virus tests the extracts (kindly supplied by Dr. J. F. A. P. Miller, of this Institute) were prepared from thymus, spleen and lymph nodes (to be referred to collectively as lymphatic tissue) derived from $Ak \times T_6, F_1$ mice with leukæmia originally induced by the Gross virus. The non-viræmic control was an extract from the same tissues from healthy adult C_3H mice. Extraction was undertaken by the homogenization of the tissues in isotonic saline (20 per cent w/v) followed by the isolation of cells and their debris by centrifugation (1,400*g* for 15 min; 7,000*g* for 10 min) and then by filtration through a 'Selas 02' porosity candle under vacuum. The extracts were subjected to an amino-acid analysis, to obtain some idea of their constituent proteins. Although the amino-acids predominant in basic proteins were detected, their proportions were rather low; percentages by weight: lysine, 6·4; arginine, 3·3; isoleucine, 3·3; leucine, 9·1. These proportions were not considerably above those found in albumins and globulins of mouse serum, thus indicating that the presence of large quantities of basic proteins in the tested extract was rather improbable.

In the Moloney virus experiments, the material (kindly supplied by Dr. J. B. Moloney of the National Institutes of Health, Bethesda, U.S.A.) was normal or viræmic plasma from *BALB/c* mice. The virus was concentrated by differential centrifugation so that a corpuscle-free pellet derived from 10 ml. of whole blood was finally suspended in 1 ml. of 0·5 M sodium citrate. The leukæmogenic efficiency of this virus concentrate (assayed in Dr. Moloney's laboratory) was found to be ED_{50}/ml. $\times 10^{-4.5}$: 50 per cent of the *BALB/c* mice which received $10^{-4.5}$ dilution of the virus when newly born showed spleens which weighed in excess of 150 mg at 28 days post-inoculation. The material for the control genetic test was normal *BALB/c* mouse plasma, which was subjected to the same differential centrifugation procedures used in the preparation of the virus concentrate. The proteins in the tested material (normal and viræmic plasma) were also analysed for the constituent amino-acids. The proportions of these acids were on the whole comparable to those obtained for the proteins from the lymphatic tissue extract. The percentages by weight of the amino-acids (predominant in basic proteins) in the analysed samples were: lysine, 7·8; arginine, 3·9; isoleucine, 3·2; leucine, 9·9.

For the mutagenicity tests the various agents were administered in isotonic solutions by micro-injection into

the hæmocœl of adult males (30 ± 5 h after eclosion) of the Oregon-*K* stock. The mutations scored in the progeny of the treated males were viable chromosome fragments and visibles (morphologically detectable changes)—both the sex-linked recessives and the autosomal dominants (especially *Minutes*). These mutations were detected by the attached-*X* technique with the markers: yellow (*y*), vermilion (*v*) and forked (*f*). Scoring for the visibles was restricted to the males only, since the slight *Minutes* (showing thin macrochætes) were difficult to detect in the females in conjunction with the forked marker which also affected the shape of the bristles. In all experiments the progeny of the treated males were fractionated into broods by repeated matings to an equal number of virgin females at 3-day intervals: the mutation rates in the successive matings were determined separately. Breeding was undertaken in mass cultures, with a maximum of ten pairs per half-pint bottle. For control purposes, males of the same stock and age were injected with isotonic saline and subjected to the foregoing attached-*X* technique. The spontaneous mutation rate detected in the male progeny over 7 broods (21 days after treatment) reached a mean value per thousand tested gametes of 0·95 ± 0·11 for the *Minutes*, and 0·15 ± 0·05 for the sex-linked recessive visibles[2]. No hyperploid females were detected among an observed sample of 80,000 progeny, which virtually excluded the spontaneous occurrence of large viable *X*-chromosome fragments.

The overall mutagenic activity of the agents investigated is summarized in Table 1. All were convincingly active as regards the induction of small chromosome deletions resulting in the *Minute* phenotype. The induced rates in the different experiments were very significantly above the control rate (by as much as 3–7-fold). Whenever more than one concentration of the same macromolecule has been tested, the recovered mutation rate was lower with the higher dose. This is entirely due to the rapid increase in toxicity with dose, both on the injected animals and on the germ cells. In the experiments with polymethacrylic acid, only 3 per cent of the injected males survived the higher dose (1 per cent) for 7 days and none gave any progeny after the sixth day. Even with the lower dose of this polymer (0·1 per cent) the survival rate at the end of the first week was still low (15·7 per cent) and their fertility was considerably lower than among the controls. This suggests that the mutations recovered in the mutagenicity tests with macromolecules are probably only a small proportion of those actually induced; the remainder being eliminated among the cells killed through cytotoxicity. The tests with the lower concentrations, therefore, are probably more representative of the actual mutagenic potency.

The synthetic polymers tested, like the natural macromolecules, were virtually ineffective in the induction of viable chromosome fragments. The hyperploid females induced by the various agents were as follows: polyglutamic acid, 1/8,863; polymethacrylic acid, 1/12,919; polyadenylic acid, 1/24,831; leukæmic (Gross virus) mouse lymphatic tissue extract, 2/82,051; leukæmic (Moloney virus) mouse plasma, 1/58,343. No fragments were recovered with polyuridylic–cytidylic acid, 0/48,916; normal mouse lymphatic tissue extract, 0/25,009; and normal mouse plasma, 0/43,560. These results add further support to the interpretation[1,2] that the induction of small chromosome deletions by macromolecules is the outcome of gene inactivation *in situ*, rather than the induction of chromosome breaks.

In contrast to the mutagenic efficiency of the tested agents in the induction of small deficiencies (*Minutes*), their activity as regards the point mutations (sex-linked recessive visibles) was not very dramatic. Although there was some rise in the rate of visible mutations in most tests, the induced frequency did not reach statistical significance except in the Gross virus series. The viræmic lymphatic tissue extract gave a rate of visible mutations considerably higher than the spontaneous rate (P = 0·00012) and also well above that induced by the non-viræmic extract of the same tissue (P = 0·0094). Unfortunately, however, the same mutagenicity did not occur with Moloney virus: the mutation rate (as regards the visibles) was the same with the normal and viræmic plasma, being insignificantly higher than the control level ($P \simeq$ 0·1). The difference in mutagenicity between the Gross and Moloney extracts is rather unexpected, since both viruses are of the RNA type, and are known to induce leukæmia in mice. This, however, does not exclude the possibility that some differences might occur in the biological activity of the two viruses in the fly's hæmocœl.

The significance of the cell stage during spermatogenesis on the activity of the tested agents was assessed on the basis of the variation in the mutation rate in different progeny fractions of the treated males. As with other macromolecules[2], this comparison was undertaken on the basis of the frequency of *Minutes* in the first 9 days progeny and that occurring in still later offspring (the 10th and later days after treatment). It should be recalled that mutations recovered in the earlier period were induced in the post-meiotic stages (sperm and spermatids), whereas those detected in the later interval must have occurred in germ-cells treated in the meiotic and premeiotic stages (spermatocytes and spermatogonia). The mutation rates induced in these two sectors of the germ line with the various agents are shown in Table 2. With polymethacrylic acid and poly-A there was conclusive evidence that the mutagenicity was significantly higher in the post-meiotic stages. In this respect, the mode of action of these agents simulates that ascertained for DNA. Polyglutamic acid was extremely toxic to the premeiotic germ-cells, thus not permitting the recovery of sufficient late progeny for a satisfactory determination of the mutation rate. Poly-UC, like RNA, was slightly more mutagenic in the early germ-cells. With the various tissue extracts (mainly heterologous proteins) there were no dramatic differences in activity in the various sectors of the germ

Table 2. The Mutation Rate (*Minutes*) in the Early (0–9 Days) as compared with the Late (Tenth and Later Days) Progeny, induced by Various Polymers and Cell-free Extracts

The limits of the mutation rates for the first two compounds are based on the Poisson expectation ($P = 0.025$)

Agent	Progeny sampled						Significance of difference P

line. There was some indication, however, that the viræmic lymphatic tissue extract (Gross virus) might be slightly more active in the post-meiotic stages.

The mutagenicity of the various macromolecules relative to DNA is represented graphically in Fig. 1. This was measured as the ratio of the mutation rate induced by each agent to that occurring with DNA at the same concentration. Where more than one concentration was tested for the same agent, comparison was based on the mutagenicity results with the lowest dose, so as to minimize the complications due to cytotoxicity. The standard deviation for each mutability ratio (vertical lines in Fig. 1) was estimated on the basis of the binomial variances of the mutation rates entered in its calculation. The differences in mutagenicity between agents were fairly marked as regards the induction of chromosome deletions (*Minutes*). Polymethacrylic acid was most outstanding among the tested compounds, in so far as it was nearly four times as active as DNA. The mutagenicity of polyadenylic acid was 2·5 times that of DNA, which is somewhat lower than that of polymethacrylic acid, although not significantly so ($P = 0.12$). It is, therefore, probable that the activity of polynucleotides (especially those of purines) is not different from that of unnatural anionic polymers. The remaining agents fell clearly into two groups: one with a higher activity than DNA (by a factor of 1·5–2), while the other was somewhat less effective (giving 0·2–0·7 the mutagenicity of DNA). The more active agents were mainly heterologous proteins, whether basic (histones), acidic, or neutral (albumins and globulins in the extracts of Moloney and Gross virus series). The group of compounds of lower mutagenicity than DNA was very heterogeneous, including poly-UC, polyglutamic acid, DNP and RNA. There is no obvious common feature (as regards chemical structure) that might account for their comparative inactivity.

A comparison was also undertaken of the mutagenicity of the various agents, relative to DNA, as regards the induction of sex-linked recessive visibles (Fig. 1). This comparison proved to be more ambiguous than that based on the *Minutes*. The extreme rarity of the induction of visibles with the macro-molecules resulted in large sampling errors in the estimation of their relative mutability ratios, which made it difficult to establish significant differences between agents. On the whole, however, there was a considerable similarity in the order of activity of the different agents on the basis of the two classes of mutation; but with narrower differences for the point mutations. Nevertheless, deviations in the rank of activity for *Minutes* and visibles did occur with two agents, which might be indicative of some differences in their mutagenic mode of action. Foremost in this connexion is the position of the cell extract with Gross virus, which showed maximal activity as regards the visibles, but only an intermediate efficiency (equivalent to the non-viræmic extract) as regards the *Minutes*. This could mean that the virus was predominantly effective in the induction of the point mutations (visibles) whereas the tissue proteins (common to both the normal and viræmic extracts) were mainly active as regards the induction of deletions (*Minutes*). Another compound which showed rank deviation as regards the two classes of mutation was polyadenylic acid. It was more active than DNA as regards the induction of *Minutes*, but less effective in the production of visibles. This suggests that poly-A is preferentially effective in the induction of small chromosome deletions, rather than point mutations.

It has already been pointed out[1] that the mutagenicity of DNA in metazoan cells does not involve a specific exchange between the exogenous DNA and particular

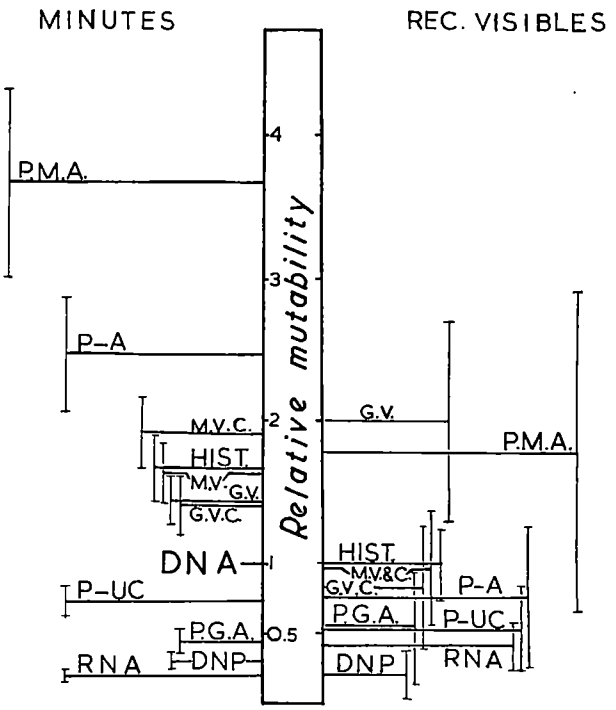

Fig. 1. Mutagenicity of natural and synthetic polymers relative to DNA: left half, *Minutes*; right half, sex-linked recessive visibles. Relative mutability was measured as the ratio of the mutation rate induced by each agent to that of DNA at the same injected concentration. DNA, deoxyribonucleic acid; DNP, deoxyribonucleoprotein; G.V., Gross virus (in mouse lymphatic tissue extract); G.V.C., Gross virus control (mouse lymphatic tissue extract); Hist., histones (calf thymus); M.V., Moloney virus (in mouse plasma); M.V.C., Moloney virus control (mouse plasma); P–A, polyadenylic acid; P.G.A., polyglutamic acid; P.M.A., polymethacrylic acid; P–UC, polyuridylic-cytidylic acid; RNA, ribonucleic acid

gene loci. Transformation at specific genes by the injection of DNA of the wild-type did not occur and mutagenicity was not restricted to the homologous material. Later investigations showed that the DNA type of mutagenicity also occurred with other cellular macromolecules, such as RNA, DNP and histones. It was accordingly suggested[2] that the mechanism involved was probably physical, involving the 'coverage' of some gene loci on the template chromosome, thus preventing their coding in the replica. The nature of the process of locus 'coverage' was unknown, but it was thought possible that it could be mediated by surface or electrical phenomena. The results summarized in Fig. 1, however, are incompatible with the above physical interpretation. There was no obvious correlation between the physical properties of the molecules tested (whether as regards size or charge) and their biological activity. Polynucleotides of the same charge (−ve) and roughly the same molecular weight showed considerable differences in mutagenic efficiency: poly-A was more active than DNA, while poly-UC was less effective. On the other hand, the activity of the positively charged histones was higher than that of DNA and approached that of poly-A.

The strongest evidence against the template coverage interpretation came from our recent work on the distribution of *Minutes* induced by different agents. A considerable specificity as to the site of genetic damage occurred with different macromolecules. With DNA (both homologous and heterologous), the majority of the induced deletions—about 80 per cent—involved the same segment on the fourth or 'dot' chromosome (most of segment 102 on the salivary chromosome map), whereas with radiation about 30 per cent of the deletions occurred in the same chromosome[3]. The proportion of fourth chromosome *Minutes* varied considerably with the other polymers[4] (both natural and synthetic), being highest with polyadenylic acid (about 55 per cent) and lowest with polymethacrylic acid, where it was of the same order as after irradiation. This differential activity of macromolecules on the genome immediately excluded any random physical mechanism and suggested some biochemical control, probably of an enzymatic nature. Support for this possibility came from the fact that ionic polymers, which were the most effective agents as regards the induction of *Minutes*, were also shown to be inhibitory to a number of biological systems[6], including enzymes, bacteria and viruses. The nature of the enzymatic disturbance that could lead to the induction of chromosome deletions has recently been indicated by the mutagenicity results with substituted nucleosides[5]—especially 5-fluorodeoxyuridine. This compound, which was shown to be a specific inhibition of thymidylate synthetase[7], was found to induce the macromolecular type of mutagenesis in *Drosophila*, in so far as it was predominantly active in the induction of *Minutes*. It is highly probable, therefore, that these mutations arise through the inhibition of cellular enzymes which, directly or indirectly, affect DNA synthesis: oxidases, phosphorylases, synthetases or polymerases. According to this interpretation, the variation in the induction of *Minutes* with the different polymers could arise as a consequence of differential enzymatic inhibition, coupled with the known variations in the time of replication of different segments of the chromosome complement[8,9].

The important question as to the mutagenic activity of tumour viruses still remains undecided. Experiments with cell-free extracts from mouse tissues, with and without Gross virus, suggested that the presence of the virus might have significantly enhanced the rate of point mutations (sex-linked recessive visibles). On the other hand, parallel tests with mouse plasma (from normal and leukæmic animals) did not reveal an increase in the rate of visibles in the presence of Moloney virus. The mutagenicity of the leukæmogenic viruses as regards the induction of chromosome deletions could not be determined, since the heterologous material (mainly soluble proteins of mouse tissues) was also active. To determine the activity of the pure virus, it will be essential to free it completely from the mouse proteins. Whether this proves feasible with leukæmogenic viruses still remains to be seen. On the other hand, it should be possible to isolate the RNA of the virus, at least from the plasma of leukæmic mice infected with Moloney virus. The investigation of the mutagenic efficiency of virus nucleic acids is now in progress.

We thank Profs. A. Haddow and J. A. V. Butler for their interest. We also thank Prof. S. Ochoa (New York University Medical Centre), Dr. J. B. Moloney (National Institutes of Health, Bethesda, U.S.A.), and our colleagues, Dr. P. Alexander and Dr. J. F. A. P. Miller, for supplying the material used in the work recorded here, and Miss P. Simpson and Miss D. Purkis for the amino-acid analyses.

This work was supported by grants to the Chester Beatty Research Institute (Institute of Cancer Research: Royal Cancer Hospital) from the Medical Research Council and the British Empire Cancer Campaign for Research, and Public Health Service research grant *CA*-03188-08 from the National Cancer Institute, U.S. Public Health Service.

INHIBITION OF INTERFERON BIOSYNTHESIS BY ACTINOMYCIN *D*

By Prof. ROBERT R. WAGNER

Department of Microbiology, Johns Hopkins University School of Medicine, Baltimore, Maryland

VIRAL infection of vertebrate cells often results in the synthesis of interferon, a protein which inhibits multiplication of the same virus that induced its formation or a wide variety of unrelated viruses[1]. This observation is understandably of considerable interest as one possible mechanism of intrinsic cellular defence against viral infection. Definitive biological investigations of this phenomenon have been hampered by difficulties encountered in purifying interferon, but some progress has been made recently in characterizing its physicochemical properties[2] and mechanism of antiviral action[3]. Even less is known about the synthesis of interferon at the cellular level. In a recent analysis of this subject[1], three major alternatives, in increasing order of likelihood, were considered as possible pathways for synthesis of interferon: (1) that interferon synthesis is directed by nucleic acid of the infecting virus; (2) that interferon precursors normally present in the uninfected cell are activated by the infecting virus; (3) that interferon synthesis is a latent cellular function induced by viral infection (or other stimulus).

The suggestion was also made that insight into this problem could be gained by the use of selective antagonists of nucleic acid and protein synthesis.

The antagonist with the greatest potential value is actinomycin *D* because of its capacity to block cellular RNA synthesis without inhibiting synthesis of viral RNA[4]. The literature contains several reports[5] on the effectiveness of actinomycin in preventing interferon synthesis without inhibiting multiplication of RNA viruses used to induce its formation. In fact, in the presence of actinomycin the yields of infecting virus may be significantly greater than anticipated[5], presumably owing to suppression of endogenous interferon. The present experiments provide evidence for the cellular site of interferon synthesis based on this selective action of actinomycin.

The feasibility of these experiments depended on the availability of virus–cell systems in which interferon production would begin several hours after infection rather than days. The protocols also called for consistently high final yields of interferon in control-infected cultures. Two such systems satisfied these conditions. In one, primary monolayer cultures of chick embryo (CE) cells were infected with Chikungunya virus; in the other monolayers or suspensions of strain *L*-929 (L) cells of murine origin were infected with a vaccine strain of Newcastle disease virus (NDV). Chikungunya virus was cultivated in brains of new-born mice and prepared as a 10 per cent suspension of emulsified brain from moribund infected animals. The titre of the stock Chikungunya virus suspension determined by intracerebral titration in new-born mice was 10^9 LD_{50}/ml. The stock NDV suspension was prepared from allantoic fluid gathered from 12-day-old chick embryos 48 h after infection; the hæmagglutinin titre of this material was 512 when tested with 0·5 per cent chicken erythrocytes. Both viruses produced only indistinct plaques on CE cell monolayers and neither was cytopathogenic for L cells except at very high multiplicities.

As previously described[6], interferon activity was assayed by the plaque-inhibition method. Fluids removed from infected cell cultures were freed of residual virus by 3 cycles of centrifugation at 100,000*g* followed by dialysis for 24 h at *p*H 2. After neutralization by further dialysis at *p*H 7, the supernatant fluids were diluted serially in two-fold steps and titrated on cells of the same type as those in the original cultures. Confluent monolayers of CE cells in 100-mm plastic plates were drained of growth medium (lactalbumin hydrolysate, 4 per cent calf serum) and exposed for 1 h to 0·5 ml. of each interferon dilution. These cultures and appropriate controls were then infected with an estimated 100 plaque-forming units (P.F.U.) of Eastern equine encephalitis (EEE) virus and overlayered with medium containing 0·95 per cent agar and neutral red. Similar procedures were used for titrating interferon on L cells grown in 60-mm plastic plates in medium 199 with 10 per cent calf serum. In these latter assays monolayers of L cells were exposed for 1 h to 0·2 ml. of each interferon dilution, infected with approximately 100 P.F.U. of encephalomyocarditis (EMC) virus, and then covered at 40-h intervals with 2 agar overlays, only the second of which contained neutral red. Plaques were scored on both CE and L cells after incubation for 44–48 h in a humidified atmosphere of 5 per cent carbon dioxide. The titre of interferon was read as the reciprocal of the dilution at which the plaque numbers in duplicate plates were reduced by at least 50 per cent of the control counts. The method is sensitive and reproducible.

Interferon synthesis was first examined in monolayer cultures of CE cells infected with Chikungunya virus. In these experiments, a series of identical flasks contained approximately 2×10^7 cells and the virus input was 10^8 LD_{50}. After a period of 1 h for virus adsorption, the cell layers were washed and covered with 10 ml. of maintenance medium. At intervals after virus adsorption, the medium was completely withdrawn from each of 3 cultures for

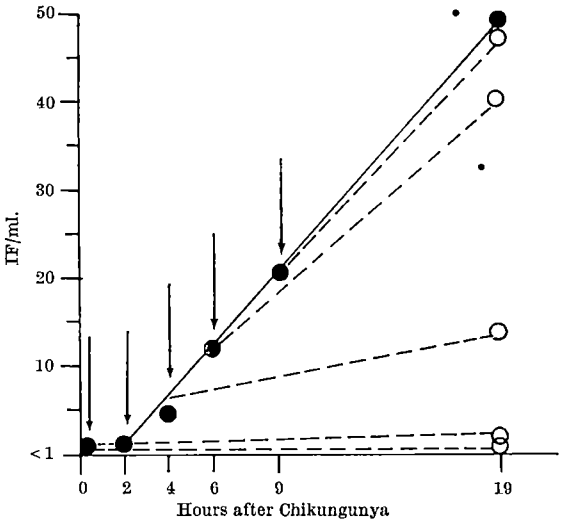

Fig. 1. Synthesis of interferon (IF) by CE cells infected with Chikungunya virus. The solid line and closed circles show the mean interferon content of control flasks at intervals after infection. The open circles and broken lines show mean interferon titres in three flasks after exposure of cells to actinomycin *D* (2 μg/ml.) at times indicated by arrows. As noted in the text, interferon synthesis was interrupted by actinomycin added to cultures by 3–4 h after infection but not by 6 h or later

interferon titration and replaced with an equal volume of fresh medium containing 2 μg/ml. of actinomycin. Finally, the actinomycin-containing fluids were gathered from all cultures at 19 h after infection and assayed individually for their interferon content. Actinomycin was removed from the media by the dialysis procedures used for processing the interferon samples.

Fig. 1 shows the rate of interferon synthesis in cultures of infected CE cells and the effect of actinomycin on final interferon yields. Interferon first appeared in the medium between 2 and 4 h after infection. Thereafter, as previously noted by Heller[5], interferon titres increased linearly to a maximum level at 19 h. When actinomycin was present in the medium from time 0 (the end of virus adsorption) or from 2 h after infection, interferon synthesis was completely inhibited. If exposure to actinomycin was delayed for 4 h, the time at which interferon was first

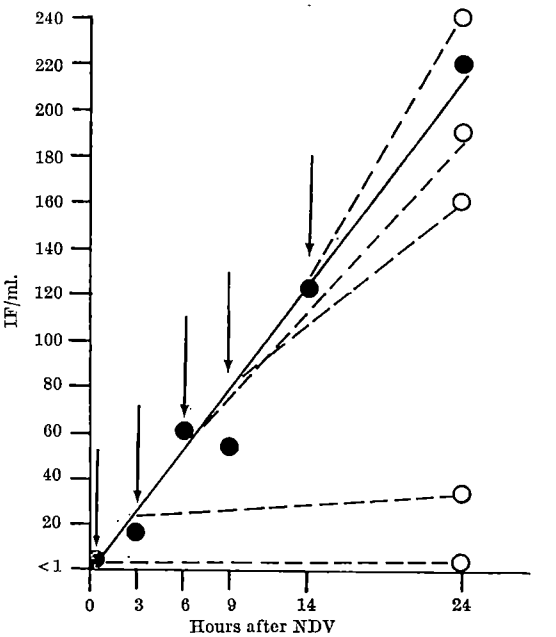

Fig. 2. Synthesis of interferon (IF) by L cells infected with Newcastle disease virus. The arrows indicate the times at which 2 μg/ml. of actinomycin were added to each of three culture flasks. See legend of Fig. 1 and text

detected, the titres at 19 h were considerably reduced, equivalent to the levels in control cultures at 6 h. The presence of actinomycin in the medium from 6 to 9 h after infection did not significantly influence the final yields of interferon.

Fig. 2 reveals that virtually identical results were obtained when monolayers of 6×10^6 L cells were infected with NDV at a multiplicity of about 5. In the absence of actinomycin the delay in appearance of interferon was at least 3 h. Once again, the ensuing rate of interferon synthesis was approximately linear; maximum titres were reached within 24 h after infection. Cells exposed to actinomycin (2 μg/ml.) at time 0 or 3 h were incapable of producing interferon, but by 6 h the interferon-producing capacity of the infected cells was not altered by actinomycin. Entirely comparable results were obtained in investigations with suspended L cells, although the final yields of interferon were generally lower than those from monolayer cultures.

The results strongly favour the hypothesis that interferon synthesis is under genetic control of cellular DNA rather than viral nucleic acid. The time-course of interferon production and the inhibitory effect of actinomycin appear to preclude the possibility that viruses activate a preformed precursor in the uninfected cell. The function of the infecting virus remains to be determined, but it seems likely that interferon synthesis is initiated in a manner similar to that of inducible enzymes. Another analogy can be found in the cell-directed synthesis of 'uncoating protein' induced by infection with pox virus[7]. The delay in onset of interferon synthesis can be attributed, in part, to the requirement for *de novo* production of messenger RNA from information encoded in cellular DNA. The failure of actinomycin to interrupt interferon synthesis late in infection suggests that the bulk of the messenger RNA is formed within 6 h and, once formed, is relatively stable.

This research was supported by grants from the U.S. Public Health Service and the National Science Foundation. I thank Miss Ruth M. Snyder for her assistance.

FIRST RECEPTOR IN INTESTINAL SUGAR TRANSPORT: THE EFFECT OF PHLORIDZIN AND OF CETRIMIDE ON THE INTESTINAL ABSORPTION OF α-D-GLUCOSAMINE, L-GLUCOSE AND D-XYLOSE

By S. L. HART and Dr. J. A. NISSIM

Department of Pharmacology, Guy's Hospital Medical School, London, S.E.1

THE absorption of many nutrient substances by the intestine can proceed against higher concentration in the blood plasma. The term 'active transport' has been used to describe absorption against a concentration gradient, but some workers[1] use it to include all transport in which the cell plays an active part, even though the substance may not be absorbed against a gradient. To avoid confusion, we shall adopt Danielli's[2] term 'facilitated diffusion' for the latter. Using the criterion of absorption against a gradient for active transport, Wilson and Landau[3] examined a large number of carbohydrates and classified them accordingly. Thus, Crane[4] was able to specify the minimum structural requirements in the carbohydrate molecule for its active transport across the intestinal mucosa.

It has already been established that in the intestinal absorption of glucose two receptors are involved in series[5], receptors which are blocked totally by phloridzin and cetrimide respectively. This fact renders Crane's structural characterization without much effective value, for we now require the interaction of the two receptors with the different carbohydrates to be specified separately. We also know now that the inhibitors of the first and second receptor are not equivalent in effect, for of the two inhibitors, only cetrimide produced leakage of blood glucose into the intestinal lumen in rabbits, guinea-pigs, rats and mice, while phloridzin produced leakage only in mice (Nissim, unpublished observations). Substances closely related to D-glucose, such as D-glucosamine and L-glucose, or the pentose D-xylose, which were shown not to be transported against a gradient[3], have been assumed to be absorbed by simple diffusion. This assumption no longer seems justified for an absorption mechanism which involves two receptors, since failure of transport may occur at either one of the two receptors only. Furthermore, the original experiments of Wilson and Landau were carried out entirely on an *in vitro* intestinal sac preparation from hamsters. The sensitivity of the method could also have failed to demonstrate smaller degrees of active transport. Finally, the first receptor may in fact be concerned only with entry, so that investigations involving the criterion of transport against a gradient may not be sufficiently informative. These reasons made it clear that the absorption of carbohydrates, which have been considered to be transported by simple diffusion, must be investigated afresh with the foregoing points in mind.

The effects of phloridzin and cetrimide on the intestinal absorption of α-D-glucosamine hydrochloride, L-glucose and D-xylose were examined in pure strain male *C3H* mice and male albino rats. The effect of combinations of different concentrations of phloridzin and cetrimide was also examined in *C3H* mice. 0·2 per cent (w/v) of the carbohydrate—the glucosamine calculated as base—dissolved in 0·9 per cent sodium chloride was circulated through the small intestine of the anæsthetized animals by the intraluminal perfusion method[5]. In preliminary experiments with *C3H* mice, 25 ml. of fluid, containing 50 mg glucosamine, was circulated for 0·5 h. In all subsequent experiments, 10 ml. of fluid, containing 20 mg carbohydrate, was perfused in mice, and 20 ml. containing 40 mg was perfused in rats, for 1 h, to give higher percentage absorption. The sugars were estimated by a modification of the method of Haslewood and Strookman[6].

α-D-*Glucosamine*. Half-hour experiments. The same procedure was followed as previously for the absorption of D-glucose (34·6 ± 0·9 per cent) in *C3H* mice, so that the absorption of glucosamine could be directly compared with that of D-glucose. The mean percentage absorption of D-glucosamine in three control experiments was 2·31 ± 0·24, while the mean for three experiments with 10^{-3} phloridzin

Table 1. Effect of Drugs on the Absorption of α-D-Glucosamine in the Small Intestine of *C3H* Mice

Drugs	No. of animals	Percentage absorption (mean ± *S.E.*)	*P*
(Control)	10	22·0 ± 1·8	
Cetrimide, 10^{-3}	6	25·4 ± 2·1	< 0·3 > 0·2
Phloridzin, 10^{-4}	8	11·0 ± 1·2	< 0·001
Phloridzin, 10^{-4} + cetrimide, 10^{-3}	3	27·3 ± 2·4	< 0·2 > 0·1
Phloridzin, 10^{-4} + cetrimide, 10^{-4}	3	8·3 ± 0·5	
Phloridzin, 10^{-4} + cetrimide, 5×10^{-5}	12	7·4 ± 0·6	< 0·01 (compared with phloridzin 10^{-4})

was $-0{\cdot}38 \pm 0{\cdot}28$. Although the difference was small, it was highly significant with $P < 10^{-3}$.

One-h experiments. (*a*) *C3H* mice (Table 1). Even at a concentration of 10^{-4}, phloridzin reduced absorption to 50 per cent of the control value, while 10^{-3} cetrimide had no inhibitory effect. An interesting result was obtained with drug combinations, for while low concentrations of cetrimide potentiated the inhibitory action of 10^{-4} phloridzin ($P < 0{\cdot}01$), the higher concentration of 10^{-3} cetrimide completely nullified it.

Table 2. Effect of Drugs on the Absorption of α-D-Glucosamine, L-Glucose and D-Xylose in the Small Intestine of Albino Rats

Sugar	Drug	No. of animals	Percentage absorption (mean ± *S.E.*)	*P*
α-D-Glucosamine	(Control)	4	10·9 ± 1·2	
	Cetrimide, 10^{-3}	6	11·9 ± 0·6	
	Phloridzin, 10^{-3}	6	0·75 ± 0·7	⩽0·001
L-Glucose	(Control)	12	12·6 ± 1·1	
	Cetrimide, 10^{-3}	4	13·3 ± 1·3	
	Phloridzin, 10^{-3}	4	−3·7 ± 2·6	⩽0·001
D-Xylose	(Control)	12	22·0 ± 1·6	
	Cetrimide, 10^{-3}	12	20·3 ± 1·3	
	Phloridzin, 10^{-4}	8	13·2 ± 0·7	< 0·001
	Phloridzin, 10^{-3}	4	−0·5 ± 0·7	

(*b*) Albino rats (Table 2). 10^{-3} phloridzin produced practically total inhibition of D-glucosamine absorption. Cetrimide had no effect.

L-Glucose and D-xylose. Total block of L-glucose absorption was obtained with 10^{-3} phloridzin (Table 2). The negative value is attributed to error in the L-glucose determination. Cetrimide again had no effect. The absorption of D-xylose was practically halved by 10^{-4}, and completely blocked by 10^{-3}, phloridzin, while cetrimide had either a negligible or no effect.

The intestinal absorption of the three sugars, namely, D-glucosamine, L-glucose and D-xylose, amounted to no more than a fraction, 1/10–1/20, of the absorption of D-glucose in mice and rats. Theoretically, this absorption could be effected by simple diffusion, facilitated diffusion or active transport, alone or in combination. A striking result was the inhibition of the absorption of the three sugars by phloridzin. For all three sugars, inhibition was apparently complete at 10^{-3} phloridzin, so that no simple diffusion, apart from that through the portals of entry which are blocked by phloridzin, could occur. The phloridzin receptor must be associated with the portal of entry for these sugars in such a way that phloridzin blocks either the appropriate membrane pores through which simple diffusion of these substances occurs or an unknown process of facilitated diffusion. Facilitated diffusion may involve carrier transport across the membrane, or the walls of the pores themselves offer a pattern of forces which facilitates to some extent the passage of glucose, probably through hydrogen-bonding structures as suggested by Stein and Danielli[7]. It would be virtually impossible at this stage of knowledge to distinguish between simple diffusion through critical-size pores and facilitated diffusion inside the pores, for both mechanisms offer a basis of competition for transfer through the pores, and both are saturable. Facilitated diffusion, involving a mechanism of carrier transport across the membrane, will be later excluded deductively.

The next interesting result regarding the absorption mechanism of the three sugars was the absence of inhibition with cetrimide. This is in marked contrast to the effect of this substance on D-glucose absorption[5]. The only possible interpretation for the difference is that these three sugars do not share the second receptor for D-glucose, which is the receptor clearly involved in the active transport mechanism, as is evident from the D-glucose leakage caused by cetrimide. Our conclusion is in direct contradiction with that arrived at recently by Alvardo[8], who studied D-xylose transport by hamster small intestine *in vitro*, and found that it was inhibited by phloridzin, Na^+ lack, anaerobiosis and 2,4-dinitrophenol (DNP). These results led him to conclude that although this sugar is not absorbed against a gradient, it is nevertheless 'transported through the same pathway as the active sugars'. The 'apparent' lack of absorption against a gradient was attributed to the smaller affinity of this pentose to the receptor. Accepting this interpretation, we should expect cetrimide to be even more effective in displacing D-xylose from the receptor than D-glucose. It is therefore necessary to find other explanations for Alvardo's results. Inhibition by phloridzin need concern only the entry receptor and is energy independent. Alvardo argued that both anaerobiosis and DNP must inhibit a second reaction which is energy-dependent, and since D-glucose had been shown to block the absorption of D-xylose[9], he concluded that they must share the same active transport mechanism. Inhibition of D-xylose transport by anaerobiosis may not be considered established at present, for the results of Alvardo are contradicted by those of Salomon *et al.*[9], who obtained a slightly higher value for anaerobic D-xylose transport. Inhibition by DNP could be due to the inactivation—or merely alteration in the affinity constant for D-xylose—of a second receptor, distinct from that for D-glucose, and resistant to cetrimide. The block of D-xylose transport by D-glucose could occur at the first, phloridzin-sensitive, receptor. Reversal of D-xylose transport by D-glucose after equilibrium was established for the former, reported by Salomon *et al.*[9], may be accounted for by the build-up of an osmotic effect, on the serosal side of the intestinal sac, due to rapid D-glucose absorption; D-xylose would then have to flow back, particularly in the presence of an active mechanism for Na^+ transport as well.

Potentiation of the phloridzin inhibition of D-glucosamine absorption by 10^{-4} cetrimide, and the abolition of this inhibition by the larger concentration of 10^{-3}, was another noteworthy result. This may seem puzzling at first sight, particularly as cetrimide by itself had no activity. The effect of combinations of phloridzin and cetrimide on D-glucose absorption was analysed previously[5]. Synergism was in part primary, due to the blocking of the second receptor by cetrimide. A considerable part of the synergism, however, was auxiliary

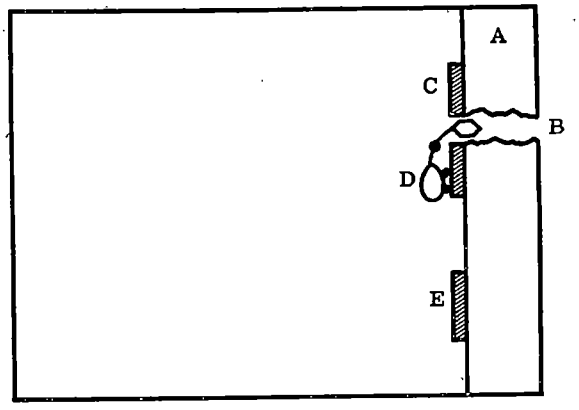

Fig. 1. Diagram representing mechanism of sugar absorption into an intestinal epithelial cell and its block by phloridzin. *A*, cell membrane; *B*, pore for entry of sugars; *C*, protein receptor for phloridzin (displaced by high concentrations of cetrimide); *D*, phloridzin molecule bound to protein, with glucose molecule in pore; *E*, silent receptor for phloridzin (displaced by low concentrations of cetrimide)

in type and caused by the conservation of phloridzin from 'silent' receptors. Evidently, the latter mechanism would still operate with sugars that are not blocked by cetrimide alone, and this would explain the present synergism between phloridzin and low doses of cetrimide on glucosamine absorption. On the other hand, the new finding of the abolition of phloridzin inhibition with higher concentrations of cetrimide must be due to displacement of phloridzin by cetrimide from the first receptor. Although cetrimide combines with the first receptor, it need not block the portal of entry if it has no D-glucose in the molecule. Even when the phloretin moiety of phloridzin is combined with other sugars, for example, galactose, it shows reduced activity[10].

Since cetrimide is an ionic surface-active agent with high affinity for protein, it is very likely that the phloridzin receptor is protein in nature. A previously established fact[5] which is of interest here is that the potentiation of phloridzin by cetrimide occurs after a relatively long interval, seemingly required for penetration of cetrimide into the cells. This would localize the protein phloridzin receptor on the inner aspect of the cell membrane. At sites where this protein receptor is adjacent to the pore, the glucose moiety of the molecule could fit into the pore, possibly with hydrogen bonding, and fail to be dislodged because of the firm phloretin attachment to the protein. A diagram representing the essential features of this model is shown in Fig. 1. It is now clear, from the new specifications of the phloridzin receptor, that it cannot be a mobile carrier ferrying sugar molecules across the cell membrane.

We thank the Medical Research Council for a personal grant to one of us (S.L.H.) and a grant for expenses.

ISOLATION OF A MUCOPEPTIDE FROM THE SURFACE OF EHRLICH ASCITES TUMOUR CELLS

By O. K. LANGLEY and DR. E. J. AMBROSE

Chester Beatty Research Institute, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

DURING recent years considerable interest has been taken in the surface membranes of tumour cells. A relative increase in the electrophoretic mobility between tumour cells and their normal counterparts has been observed in a number of cases[1,2]. It has also been shown that a high cellular mobility can be correlated with rapid invasiveness of tumour cells[3,4]. Forrester *et al.*[5] and Ruhenstroth-Bauer *et al.*[6] have shown that the electrical mobility of various tumour cells is reduced after incubation with neuraminidase, showing the important contribution of sialic acid to the cell surface charge. Furthermore, Forrester *et al.*[5], when studying the increased mobility of hamster kidney fibroblasts transformed by polyoma virus relative to the normal cell, found that the mobilities of the two cell lines were identical after incubation with neuraminidase. In the light of such work an investigation was begun to study the mode of linkage of sialic acid in tumour cell surface membranes. The Ehrlich ascites carcinoma was chosen as a suitable system on which to begin the work, as it was readily obtainable in quantities large enough for the work envisaged.

Tumour cells were collected into saline or EDTA saline from *C*-mice, by peritoneal puncture, eight to nine days after transplantation. After four washes in saline the cells were incubated at 37° C with enzyme solutions for periods of up to three hours. A 1 per cent suspension of B.D.H. trypsin in Krebs-Ringer phosphate at *p*H 7·2 was routinely used. A preparation of crystalline ficin, activated as described by Lisowska[7], has also been tried. The viability of the cells was tested after incubation, with lissamine green, when not more than a small percentage were found to stain. The supernatant from the incubation mixture after centrifugation of the cells was deproteinized by the addition of trichloroacetic acid solution. The precipitate was removed and the clear liquid then dialysed against running tap-water overnight. The retentate was lyophilized. This crude preparation was a white powder having an absorption maximum at 260 mμ in aqueous solution. On analysis, after weak acid hydrolysis, by the thiobarbituric acid method of Warren[8] it was found to contain bound sialic acid. The quantities of sialic acid released by trypsin and ficin from the cells are recorded in Table 1. These values are also expressed as a percentage of the amount of sialic acid released by neuraminidase.

To find out if other sugars were present in the sialomucopeptide, paper chromatography in two different solvent systems was attempted after acid hydrolysis. This revealed the presence of galactosamine and the possible presence of its *N*-acetyl derivative in small amounts.

An attempt was made to purify the mucopeptide, using the technique of gel-filtration. This was performed with a column of 'Sephadex *G*-50'. The peak shown in Fig. 1 is the result of plotting the values of the optical density at 260 mμ of the eluate against the elution volume. The concentrations of both sialic acid and hexosamine were also determined on lyophilized fractions of the

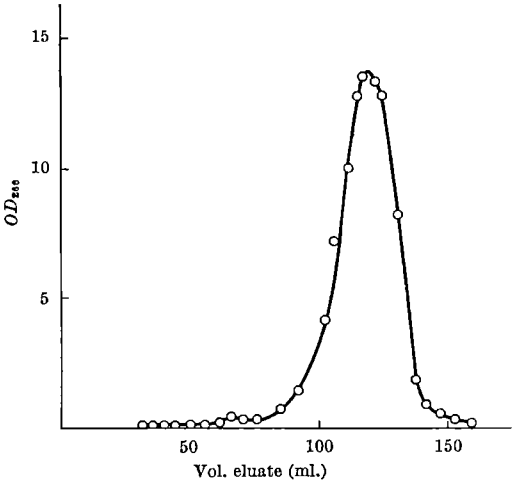

Fig. 1. Gel-filtration of the sialomucopeptide obtained by trypsin treatment of Ehrlich ascites tumour cells. The ultra-violet absorption at 260 mμ has been plotted against elution volume

eluate after hydrolysis with either 0·1 N sulphuric acid for 1 h at 80° C (for sialic acid) or 1 N hydrochloric acid in sealed 'Pyrex' tubes for 8 h at 105° C (for hexosamine). These results are shown in Fig. 2.

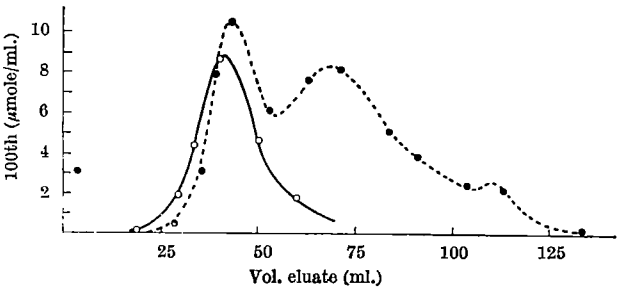

Fig. 2. Gel-filtration of the sialomucopeptide obtained by trypsin treatment of Ehrlich ascites tumour cells. The concentration of sialic acid, measured by the thiobarbituric acid assay[6] after acid hydrolysis, and the relative concentration of hexosamine in different fractions of the eluate, determined by Rondle and Morgan's modification[12] of the earlier described method of Elson and Morgan[13] and represented here by the optical density of the chromophore at 530 mμ, have been plotted against the elution volume. ●, $O.D._{530}$, Elson–Morgan reaction; ○, concentrated sialic acid

Gel filtration with 'Sephadex *G*-50' has shown the crude peptide to contain two major components, only one of which contains sialic acid. This latter component has a high molecular weight relative to the other. It is eluted in a volume approximately equal to the void volume of the column and consequently its molecular weight must be equal to or greater than the value of the exclusion limit of the gel. This value is approximately 8–10,000 for 'Sephadex *G*-50'. Another important result revealed by this technique is the coincidence of the hexosamine and sialic acid peaks in the eluate. Coupled with the evidence from paper chromatography that galactosamine is the only hexosamine present in the acid hydrolysate of the mucopeptide, and that this has probably arisen from its *N*-acetyl derivative, this indicates that both sialic acid and *N*-acetylgalactosamine are possibly linked together in the molecule. Evidence from enzymatic cleavage of sialic acid and weak acid hydrolysis of this somewhat purified material suggests that sialic acid may be terminally linked in the sugar side-chain of the molecule.

Cook[9], attempting to elucidate the mode of linkage of sialic acid in the erythrocyte membrane, prepared a sialomucopeptide by treating red blood cells with trypsin. His material contained sialic acid, *N*-acetyl galactosamine and eight amino-acids, two of which were present in trace quantities. He concluded that the saccharide chain was identical to that found in the submaxillary gland mucoproteins, namely the 6-α-D-sialyl-*N*-acetylgalactosaminoyl unit, and that it was joined through the γ-carboxyl group of glutamic acid to the peptide chain. Although the molecular weight of the sialomucopeptide prepared from the Ehrlich ascites tumour cells is very much larger than that of the erythrocyte preparation, it is interesting to note that the six major amino-acid components present in the latter are to be found in relatively large amounts in the former. The results of the amino-acid analysis of the fractions eluted from the 'Sephadex' column containing sialic acid are recorded in Table 2. These values were obtained using an EEL automatic amino-acid analyser, after the samples had been hydrolysed for 24 h with 6 N hydrochloric acid under nitrogen in sealed tubes.

The high proline, glutamic acid and glycine content of the peptide, together with the absence or very low content of aromatic side-chains, gives an amino-acid composition somewhat similar to collagen. Such an amino-acid composition will favour the stabilization of the peptide chain in an extended form[10] possibly in the collagen configuration[11]. Such a structure could lie compactly on the cell surface, which would not be possible with an α-helix. Experiments based on neuraminidase

Table 1. Released Sialic Acid

Enzyme	μ moles/ml. cells*	% Neuraminidase sensitive
Neuraminidase	$2{\cdot}60 \times 10^{-1}$	100·0
Trypsin	$2{\cdot}20 \times 10^{-1}$	84·5
Ficin	$2{\cdot}04 \times 10^{-1}$	78·5

* As determined in micro-hæmatocrit centrifuge.

Table 2. Amino-acid Composition of the Sialomucopeptide (g/100 g. Peptide)

Amino-acid	Sample 1	Sample 2
Aspartic acid	17·8	15·8
Glutamic acid	21·1	23·5
Glycine	5·7	5·6
Alanine	5·2	5·0
Valine	5·4	5·0
Leucine	5·6	5·1
Serine	5·0	5·0

Arginine	2·3	1·9

treatment of intact viable cells, and of completely disrupted cells (produced by ultrasonic degradation), showed that there was very little detectable difference between the amount of sialic acid released from intact cells and the total neuraminidase labile sialic acid of the disrupted cell. This evidence confirms the suggestion that the sialomucopeptide has originated from the cell surface. The quantitative assay for sialic acid in the purified mucopeptide gives a value of approximately 2 per cent, on a weight basis. It may be possible to differentiate further components, thus obtaining a fraction richer in sialic acid, by a technique dependent on the electrical properties of the material, such as starch-gel electrophoresis. In such a technique the sialo substance, which is endowed with a high negative charge due to the free carboxyl groups of the sialic acid residues, would be easily separable from any basic, neutral, or weakly acid substances present.

One of the disadvantages of the tumour system used is the absence of a normal cell to use as a comparison. It is hoped, therefore, to be able to perform similar investigations to those described here on normal hamster kidney fibroblasts, grown in tissue culture and on such cells transformed *in vitro* by polyoma virus. Using such a system it may be possible to detect differences in the amino-acid and sugar composition of substances comprising the cell surface membranes of normal and tumour cells.

We thank Prof. A. Haddow for his advice and Mrs. D. Purkiss for her assistance. VARIATIONS IN THE RATE OF INDUCTION OF CHEMICAL CARCINOGENESIS ACCORDING TO DIFFERING PSYCHOLOGICAL STATES IN RATS

By Dr. MARY R. ANDERSON
Algernon Firth Institute of Pathology, School of Medicine, Leeds

ENVIRONMENT modifies endocrine responses; goalkeepers secrete adrenaline while the forwards secrete noradrenaline[1], and socially-induced stress responses in mice cause a significant enlargement of the adrenal glands and temporary eosinophilia[2].

If chemical carcinogenesis is the result of an antibody induced by a carcinogen–protein complex deleting marker sites on cell surfaces as Green[3] has suggested, different forms of stress, activating different aspects of the immune mechanism, may vary the rate of chemical induction of cancer.

Four groups of 12 Sheffield strain Wistar rats, six males and six females in each group, received 0·05 g 20-methylcholanthrene (subcutaneously) to the anterior abdominal wall.

Group 1 (*contented*). Daily stroking from the nose to tail on the lap for 5 min. Two females were in a cage with the male rats, and a sterilized male with the females.

Group 2 (*stressed*). Daily injection of adrenaline (0·05 ml. 1 : 1000 subcutaneously). This dosage was stressful and caused epilation at the site of the injection.

Group 3 (*alerted*). Kept permanently in tension cages. A 60-V light fixed to the top of the cage lights up for 5 min in every hour, and is followed by an electric shock of 32 μfarads delivered to the floor of the cage. For the first few days the light and the shock were synchronized to condition the animals to associate the light with the shock. The timer was then adjusted so that the light preceded the shock by 5 min, to alert the animals for 5 min in the hour.

Group 4 (*controls*). These animals received no further treatment other than the implant of 20-methylcholanthrene.

Towards the end of the second week most of the animals had nodules of 0·5 cm to 1 or 2 cm diameter. These nodules either resolved or progressed to ulcer formation, which were larger in the females and the two adrenaline-treated females sloughed the carcinogen. In this context it might be noted that Kitary[4] found that plasma corticosterone reached higher and more persistent levels in female than in male rats under ether stress, and the adrenals of female rats were found to be more sensitive to ACTH than those of male rats.

At 40 weeks, 4 out of 12 rats in the tension cage were without tumours whereas only the 2 adrenaline-treated females out of 36 other rats were without tumours. The result appears to be significant, the *S.E.* being 2·5, giving a chance probability of about 1 in 300.

Previous work has shown that either irradiation of the draining lymph nodes, or treating them with thorotrast, delays chemical carcinogenesis[5], apparently by temporary suppression of the local immune response.

Evidence has also been presented that there is a predominantly larger flare in the side of guinea-pigs which have received subcutaneous injections of autologous (chemically induced) fibrosarcoma cell suspension and autologous spleen cells (which had been sensitized by a piece of the autologous tumour in a 'Millipore' chamber placed intraperitoneally), than there was in the other (control) side of the guinea pig which received the same autologous tumour-sensitized spleen suspension and a suspension of autologous liver cells[6]. More recent work has also shown that the spleen of a tumour-bearing rat does not need to be sensitized by the charged 'Millipore' chamber. Eight out of nine guinea-pigs showed a larger flare in the side which had received autologous spleen and tumour cell suspension, than the control side which had received autologous spleen cell suspension and autologous liver. This is further evidence of an immune response playing a part in both tumour induction and growth.

Table 1

Group	Treatment	No. developing ulcers second week after carc. inj.		No. without tumour at 40 weeks	
		F	*M*	*F*	*M*
(1)	Stroked	2/6 small	2/6 small	0/6	0/6
(2)	Adrenaline	5/5 very large	2/6 small	2/5	0/6
(3)	Tension	6/6	0/6	3/6	1/6
(4)	Control	4/6	2/6	0/6	0/6

Everett[7] showed that some strains of rat go into pseudopregnancy on isolation. Guy[8] obtained heightened contact sensitivity in guinea-pigs after they had been kept in a tension box for a few days. Winoker[9], too, showed that stress (electric shock) reduced epilation in mice painted with methylcholanthrene, and Rashkis[10] also found that stress (swimming) delayed both ascites and chemically induced tumours. In this experiment apprehension gave some protection against carcinogenesis.

A clear distinction must be made between stroking, which is a soothing process, and handling, which is alarming. Weininger[11] found that gentling rats (by handling) caused them to withstand acute stress better than normal animals. Selye[12] has shown that cardiovascular damage is the expression of the liberation of ACTH under stress, so it is possible that a mild degree of chronic stress (gentling) may raise the target's threshold to ACTH. The reverse probably happens in severe shock[13].

It has been found, too, that guinea-pigs sensitized to an allergen have a lowered threshold after electric shock or loss of sleep[14]. Bloch and Nordin[15] showed that delayed hypersensitivity in a guinea-pig to the intradermal injection of bacteria is transferable by monocytes to normal guinea-pigs. If the bacteria were injected intradermally to unsensitized guinea-pigs, they responded with an immediate Arthus-type reaction, and a circulating antibody, instead of a cell-bound one as in the delayed hypersensitivity experiments. Nilzén[16] demonstrated a rise in skin reactivity in guinea-pigs following adrenalectomy, which he says is due to the importance of the adrenal cortex in topical defence mechanism.

Darrack[17] and Murphy[18] found that adrenal steroids suppressed antibody activity, while adrenalectomy caused an increase in lymphoid tissue and circulating lymphocytes. Cortisone, however, while preventing the lymphophoresis and number of circulating lymphocytes from rising after adrenalectomy, did not affect the antibody production or Arthus and anaphylactic reactions[19]. Nicol[20] has shown that diethylstilbœstrol greatly stimulates the phagocytic ability of the reticulo-endothelial system, and that stilbœstrol *per os* cuts down the effect of stress on the plasma corticoids.

After mental stress the capillary resistance has been found to be higher in the arms of students painted with corticosteroids than in the control arms[21]. Ischæmic shock, injections of ACTH or cortisone, have been found to inhibit mitosis of normal cells but not of cancer cells[22]. This suggests that malignant cells may lack endocrine-binding sites.

If antibody attack is the essential mechanism in the chemical induction of cancer, modifying the level of circulating corticosteroids would theoretically delay the onset of neoplasia. It has been shown[23] that several forms of stimulation caused rats to have higher levels of plasma

corticosteroids than undisturbed animals Breen[24] has suggested that in an immunological sense tolerance is more important than immunity. It is believed that environmental factors play a part in controlling the degree of tolerance or immunity that is achieved, and modifying the environment, and hence the psychological state, can vary the rate of induction of chemical carcinogenesis in rats.

ANTIBODIES TO VIRUSES OF THE COLUMBIA *SK* GROUP IN SCIURIDAE IN BRITAIN

By Dr. ALBERTO D. VIZOSO and ROBERT HAY

Virus Research Unit, Medical Research Council Laboratories, Carshalton, Surrey

THE antigenically related group of Columbia *SK* viruses appears to be universally distributed. Their host range is so wide as to make this group remarkable among RNA viruses. To the species already listed as being susceptible by Jungeblut[1] we may add an isolation from a laboratory colony of Orkney voles (*Microtus orcadensis*), and also transmission of the virus to the short-tailed vole (*Microtus agrestis*) and to the bank vole (*Clethrionomys*) (Vizoso and Sanders, unpublished results). Murnane *et al.*[2] isolated a virus of the Columbia *SK* group from a pig, and Craighead *et al.*[3] also showed that pigs were susceptible to infection by encephalomyocarditis (EMC). Recently Vizoso *et al.*[4] isolated a virus of this group, resembling EMC, from a British squirrel (*Sciurus vulgaris leucourus*); this apparently healthy animal was devoid of any measurable antibody when tested against EMC virus, and the virus will be referred to as *RS*3. It lacks one of the main characteristics of the group, namely, the ability to agglutinate sheep red cells. A new isolation has been made from a grey squirrel (*Sciurus carolinensis*) trapped near the laboratory, and this animal also did not have antibody against EMC when tested by the hæmagglutination inhibition (HAI) test. The relative ease of isolation, considering the small number of animals in which it was attempted (one red squirrel and five grey squirrels), suggests infection is common. Grey squirrels are susceptible to EMC and *RS*3 virus by intranasal inoculation and develop limb paralysis or die. Sub-lethal doses presumably induce antibody response; it was therefore decided to investigate the antibody level and frequency as determined by HAI tests on serum from animals obtained from several localities. The investigation recorded here was carried out mainly on grey squirrels from Surrey, Hampshire and Buckinghamshire; a few red squirrels from Suffolk were also used.

Antibody assays were made by the HAI test using sheep red cells with serum samples taken from grey and red squirrels which had been either trapped or shot.

Since the squirrel virus (*RS*3) does not agglutinate sheep red blood cells the HAI test was applied, using a strain of EMC virus originally isolated from a chimpanzee by Helwig and Schmidt[5] and adapted to Krebs mouse ascites tumour cells by Hoskins and Sanders[6].

A second virus, provisionally identified as also being of the Columbia *SK* group (*GS*8), was also isolated from the fæces of an apparently healthy grey squirrel (*Sciurus carolinensis*) trapped in the vicinity of this laboratory.

This animal, like that of the previous isolation, showed no detectable antibody against EMC. The isolation of the virus, the characterization, ether resistance, demonstration of infectious RNA, and final identification by neutralization test against a standard EMC antiserum in suckling mice, were made as described for *RS*3. The titre reached by this virus in suckling mice was $\geqslant 10^{8.5}$, on which the EMC antiserum neutralized $\geqslant 10^{5.0}$ LD_{50}.

Unlike the previous squirrel virus *RS*3, this virus *GS*8 has the ability to agglutinate sheep red cells. The agglutinin, nevertheless, appears to be less stable than that of the standard strain of EMC, and decreases rapidly on freezing and thawing. With this virus the HAI tests were made with samples frozen once only.

The strain *GS*8 grew rapidly in Krebs ascites cells and the virus used in this test was grown in a cell suspension of these cells, ampouled, and kept frozen at $-70°$ C.

Washed sheep red cells obtained commercially from Burroughs Wellcome were used throughout at a concentration of 0·1 per cent.

Diluent for the test was PBS[7] plus an equal volume of 4·5 per cent glucose in distilled water and 0·0025 per cent gelatine. The test was incubated at 4° C overnight before reading.

All serum samples had been inactivated in a water-bath at 56° C for 30 min. 1/20,000 sodium azide was added as preservative, and the samples were stored at 4° C until required. Two-fold dilutions of serum were challenged with 8 units of virus hæmagglutinin. The significant level of antibody was arbitrarily fixed at $\log_{10} 1{\cdot}8$.

Blood samples from a total of 61 grey squirrels and 8 red squirrels were tested. None of the red squirrel samples showed any detectable antibody against the standard EMC virus. Fourteen grey squirrel samples were positive (EMC antibody-level $\geqslant \log_{10} 1{\cdot}8$). Two squirrels released in the proximity of the laboratory, which showed no traces of antibody against EMC, were recaptured after a period of five months; one still had no detectable antibody, while the other showed a level of $\log_{10} 2{\cdot}8$.

It was noticed that the incidence of EMC antibody appeared to be higher among grey squirrel samples obtained in the vicinity of the laboratory. It was therefore decided to group the samples according to the type of locality from which they had been obtained. This gave an urban group comprising animals captured in back gardens or parkland with close proximity to human habitation, and a rural group well isolated from towns or villages. The urban group with 30 grey squirrels contained 14 with significant levels of antibody against EMC. The rural group of 31 squirrels revealed no antibody. One animal in the rural area (Bucks.) showed an HAI anti-

body-level of log 1·5, which is below the significant level. Forty-nine samples of the grey squirrel sera still available were then tested using the newly isolated strain *GS*8. Of these samples (24 urban and 25 rural), 12 were found to have a significant level of antibody.

It was found that although some of the samples found positive when tested with EMC virus were also positive when tested with *GS*8, there were also some samples which were positive only to EMC or to *GS*8.

Again, as in the case of EMC, the positive samples were found in sera from animals obtained from urban areas. Only one sample in the rural areas had an antibody index of 1·5 for *GS*8, and this sample was totally negative when challenged by HAI test with EMC virus. The recaptured squirrel with positive antibody for EMC also had antibody for *GS*8. Unfortunately, there was not enough serum left from the first sample to test against *GS*8.

The numbers of squirrels showing antibody against one or two of the viruses are shown in Table 1.

Table 1. ANTIBODIES IN GREY SQUIRRELS AGAINST EMC AND *GS*8 VIRUSES

Locality	No.	*GS*8 only	EMC only	EMC and *GS*8	Total with antibody
Urban	30	4/49	6	8	18
Rural	31	0	0	0	0
Total	61	4/49	6	8	18

The results described show a fairly high frequency of antibodies to viruses of the Columbia *SK* group in grey squirrel populations, especially in urban populations when two different viruses of this group, EMC and *GS*8, are considered together. High incidence of antibody to the Columbia *SK* group was found by Barski and Lamy[8] (from ref. 1) in pygmy populations in Africa, and Warren found antibodies in 43 per cent of the wild rats on the farm where the original isolation of EMC was made from a chimpanzee. However, the investigations of Warren *et al.*[9] showed that the percentage of antibodies in wild rats can vary in different localities from nil to as much as 87 per cent. In the work recorded here, and in spite of the small sample, there appears to be a correlation between the antibody-level of the squirrel population and the proximity of human habitation. No similar correlation can be made in the case of the British red squirrel. The only samples are from a rural area, and none of the eight animals examined showed antibody to EMC. Since from this area an isolation has been made (*RS*3) of another virus of this group, differing from EMC and *GS*8 in the lack of hæmagglutinin, it is possible that some antibody could be found by the use of another test. It is tempting to correlate the higher level of antibody incidence among urban grey squirrels with the presence of rats near human habitations, since rats excrete large amounts of virus in their urine and fæces. The high incidence in the rat could, in turn, possibly be linked to the proximity of man, domestic animals, or livestock. Antibodies have been found in cattle, swine and dogs[1,2]. Insects do not appear to play an important part in the transmission of the viruses of this group, and the method of transmission still remains obscure. Fifteen adult albino mice inoculated orally with 10^5 mouse LD_{50} virus failed to show any outward signs of infection, and when killed 15 days after inoculation none showed any measurable antibody against EMC. Since at certain times of the year squirrels spend a considerable time searching for buried food, presumably by scent, and also sniff at urine traces left by other squirrels, nasal absorption would seem to be a likely route of infection. Grey squirrels inoculated intranasally with at least 10^5 mouse LD_{50} of *RS*3 virus succumb to the infection.

It is also of interest that two viruses of the Columbia *SK* group could be separated by the HAI test, but not by plating in Krebs cells, or by neutralization test in mice (to be published). This is, to our knowledge, the first time that this has been reported, and does not apply to other strains of the same group of virus. The HAI test has by now been shown to be a reliable and convenient method for the detection of antibodies of the viruses of the Columbia *SK* group; however, in a situation with two viruses, as described in this work, it may give an incomplete picture or conflicting results between neutralization tests and HAI tests, such as have been described by Craighead *et al.*[10]. A situation such as that described may explain their findings. A strain like *RS*3 which does not agglutinate need not induce the formation of HAI antibody, so its results would not be detected by HAI tests using other hæmagglutinating viruses of this group as antigens.

POTENTIATION OF THE NERVE-DEPRESSANT EFFECT OF LOCAL ANÆSTHETICS BY CARBON DIOXIDE

By PROF. G. A. CONDOURIS and A. SHAKALIS
Department of Pharmacology, Seton Hall College of Medicine and Dentistry, Jersey City, New Jersey

AN analysis of the influence of carbon dioxide on the pharmacological activity of local anæsthetics on frog and rat peripheral nerves disclosed that the gas potentiates the depressant action of the drugs[1]. These investigations have been expanded and the relationship of carbon dioxide to the drug action further characterized.

Experiments were performed on rat sciatic-tibial trunks which were isolated from the animals and subjected to a pharmacological analysis of their excitability and conduction properties in a nerve chamber in which the gaseous and fluid environments of the nerves could be selectively modified.

The drugs examined were three prototype tertiary amine local anæsthetics : procaine, lidocaine and cocaine ; the concentrations of carbon dioxide used ranged from 0 to 20 per cent. All extracellular electrolyte solutions (Tyrode's solution) were continuously equilibrated with the appropriate concentration of carbon dioxide. This was accomplished by vigorously bubbling them with the gas mixture before they were applied to the nerves and by keeping them saturated during the experiment by maintaining a constant ambient carbon dioxide concentration. Since carbon dioxide affects *p*H, sodium bicarbonate was added to the carbon dioxide containing solutions to hold the *p*H at about 7·4 ; carbon dioxide-free Tyrode's solutions contained a 2 mM sodium phosphate buffer instead of the bicarbonate and had a *p*H of 7·2.

Briefly, the experimental procedure entailed the equilibration of the trunks for 30 min (at 35° ± 2° C) in one of the Tyrode's solutions containing a specified

carbon dioxide concentration. Then the drug, dissolved in the same tyrode solution, was applied to a 15-mm segment of trunk interposed between a pair of stimulating and a pair of recording electrodes and the spike potential of the $A\alpha$ fibres evoked by supra-maximal electrical stimulation was continuously monitored. The size of the spike recorded just outside the treated segment of nerve was used to determine the ability of the nerves to conduct impulses. Most of the experiments evaluated the effects of 0 and 5 per cent carbon dioxide, but intermediate and larger concentrations were also examined. The balance of the gas mixture was oxygen.

The results illustrated in Figs. 1, 2 and 3 show that a single concentration of any of the three drugs causes two distinct quantitative levels of spike depression depending on the concentration of exogenous carbon dioxide in contact with the nerves. When the Tyrode's solution and chamber atmosphere are free of exogenous carbon dioxide, the drugs produce only a minimum depression of the $A\alpha$ spike height; procaine, 2 mM in 4 trunks, causes only a 5 per cent loss of spike height; cocaine, 1 mM in 4 trunks, a 5 per cent loss; and lidocaine, 1 mM in 4 trunks, produces no depression at the end of a 30-min period. The spontaneous recovery of some nerves from the action of the drugs in carbon dioxide-free Tyrode's solution is a real phenomenon the significance of which remains to be evaluated.

In contrast to their minor effects in the absence of exogenous carbon dioxide, the drugs produce a significantly greater conduction block when a physiological concentration of carbon dioxide (5 per cent) is introduced into the extracellular medium. Then, they produce a depression of conduction in practically every fibre. The restoration of function to the nerves following either of the two experimental procedures was never impaired.

The lowest concentrations of carbon dioxide that unequivocally enhance the action of the anæsthetics are about 2·5–3 per cent. As the carbon dioxide concentration is increased to 5, 10 and 20 per cent, the depressant actions of procaine, which was studied more extensively than the other drugs, progressively increased. A quantitative estimate of the degree of enhancement of procaine by 5 per cent carbon dioxide is provided by the fact that nerves that are maintained in carbon dioxide-free Tyrode's solution require procaine concentrations in excess of 15 mM in order to be blocked to a level equivalent to that obtained by 2 mM procaine in 5 per cent carbon dioxide. This means that the absence of carbon dioxide reduces the procaine action by about seven-fold. Conversely, the procaine concentration in normal Tyrode's solution would have to be reduced to about 0·2 mM in order to match the minimum block produced by 2 mM procaine in carbon dioxide-free Tyrode. This indicates about a ten-fold increase in procaine action proffered by 5 per cent carbon dioxide. The evidence presented supports the conclusion that the relationship of carbon dioxide to the local anæsthetic drugs is one of pharmacological potentiation in which the gas enhances the action of, at least, procaine by a factor of 7–10.

The known depressant action of carbon dioxide on nerve may explain, in part, but not completely, the observed phenomenon. Excitability threshold of the nerves used in Figs. 1, 2 and 3 was consistently elevated by 5 per cent carbon dioxide, with an average increase of 23 per cent (range 4–40 per cent). If the potentiation of the drugs were caused solely by an additive effect on threshold, then the higher concentrations of carbon dioxide (10 and 20 per cent) should result in an increase in threshold beyond that effected by 5 per cent carbon dioxide, because these higher concentrations of carbon dioxide did enhance the action of procaine to a greater extent than did 5 per cent carbon dioxide. But the results from strength-duration investigations on trunks kept in environments of 10 and 20 per cent carbon dioxide

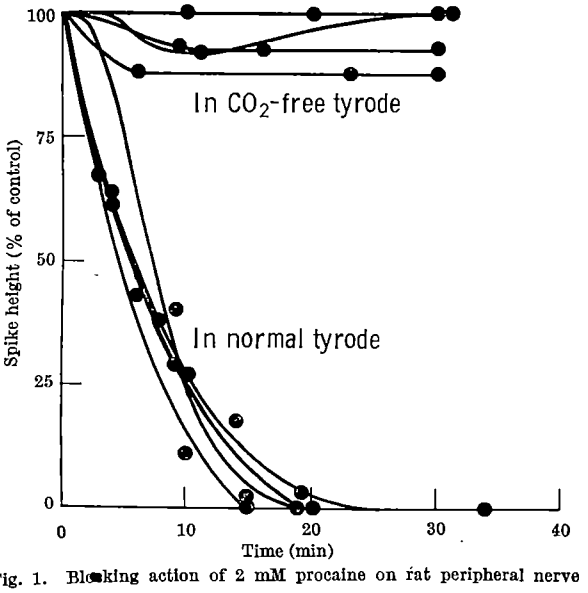

Fig. 1. Blocking action of 2 mM procaine on rat peripheral nerve

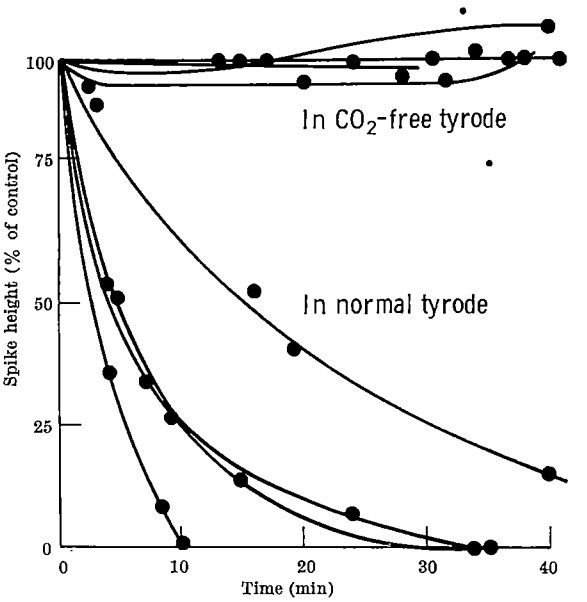

Fig. 2. Blocking action of 1 mM lidocaine on rat peripheral nerve

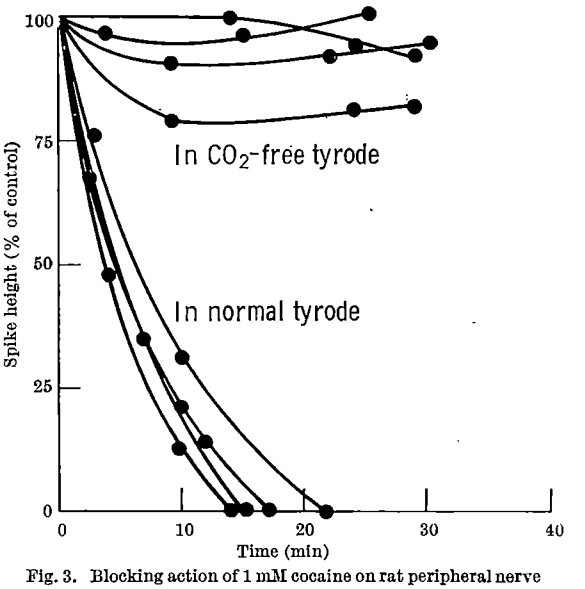

Fig. 3. Blocking action of 1 mM cocaine on rat peripheral nerve

failed to show any greater depression of excitability by the higher carbon dioxide concentrations than that already produced by the 5 per cent concentration. It seems, therefore, that some other action of carbon dioxide is involved. A change of extra-cellular *p*H by the carbon dioxide is also not the cause, because the *p*H was controlled and because, if the *p*H were lowered by carbon dioxide through carbonic acid formation, the activity of the drugs would be expected to be reduced rather than enhanced[2]. (The small difference in *p*H between carbon dioxide-free Tyrode (7·2) and 5 per cent carbon dioxide Tyrode (7·4) is not enough to account for the potentiation.) Of course, no conclusion can be made regarding the cellular *p*H change during these procedures. Another prominent action of carbon dioxide on nerve has to be considered. Lorente de Nó has shown that carbon dioxide increases the resting membrane potential of frog nerves[3]. Since the drugs used in the present investigation tend to stabilize the membrane, it is conceivable that the joint actions of the drugs and carbon dioxide on the membrane would augment each other. This would, of course, be partly reflected in an increase in excitability threshold. But this line of reasoning leads to a paradoxical situation, for, if the potentiation of the drugs by carbon dioxide were a result of an augmented and more stable membrane potential, an applied anodal current, which would raise the membrane potential, should also potentiate the action of the anæsthetics. But this is contrary to published evidence which clearly shows that, in frog nerves, anodal polarization relieves the conduction block by local anæsthetics[4,5]. An investigation of this interesting inconsistency is now in progress.

The finding that carbon dioxide can intensify the action of nerve depressants on isolated peripheral nerves raises the question whether carbon dioxide might also modify the pharmacological effects of other neurotropic drugs on other parts of the nervous system. Such a possibility is already established by several investigators[6], who have shown that carbon dioxide has an antagonistic action to the central nervous system convulsants such as pentylenetetrazol.

A MODEL OF THE INHERITANCE OF HANDEDNESS AND CEREBRAL DOMINANCE

By Mrs. MARIAN ANNETT
Department of Psychology, University of Aberdeen

THERE are many puzzles about left handedness. Left handers are often less consistent in using the left hand than right handers in using the right ; the incidence of left handedness is raised in many pathological groups and yet left handers may be of high intelligence ; several different solutions have been offered to the problem of which cerebral hemisphere leads in speech functions in left handers ; left handers seem to be more likely to recover from aphasias than right handers. It is the purpose of this article to describe a model of the inheritance of handedness and cerebral dominance which, together with a hypothesis about the direction of shifts of dominance, might account for many puzzling facts.

The Model. (1) Handedness (of human beings in the literature referred to) is determined by two alleles, *D*, which manifests right handedness and *R*, which manifests left handedness. (2) *D* is usually dominant and *R* usually recessive, but there is partial penetrance of *R* in heterozygotes. The possibility that left handedness is caused by such an imperfectly recessive gene was suggested by Rife[1] and supported by Merrell[2]. Rife's suggestion that heterozygotes may become right, left or ambidextrous is, I consider, the key to the various problems discussed here.

(3) The dominant cerebral hemisphere, meaning the hemisphere which leads in language functions, is closely linked with handedness so that: (*a*) Dominant homozygotes (*DD*) are consistent right handers with speech more highly developed in the left hemisphere. (*b*) Recessive homozygotes (*RR*) are consistent left handers with speech mainly in the right hemisphere. (*c*) Heterozygotes (*DR*) may use either hand for skilled activities and develop speech in either hemisphere. The majority of heterozygotes will develop right handedness and left hemisphere dominance, but in some heterozygotes the recessive gene will produce tendencies to left handedness. The sinistrality may vary from slight to strong, but careful examination should probably reveal the presence of the dominant gene in some skill with the right hand. In the course of normal development the dominant gene probably increases control so that right handedness and mediation of speech by the left hemisphere are characteristic of heterozygous adults.

However, should there be any physical trauma either to the hemisphere or to the limbs, the heterozygote may develop the use of the alternate hemisphere and limb. It is being suggested that heterozygotes only can shift dominance to compensate for injuries. Homozygotes injured in the hemisphere predisposed to become dominant will be 'ambilevous'—or equally unskilful with either hand—and prone to disorders of speech.

Illustration of the Model. Assuming the proportions of *D* and *R* in a population to be $D=0{\cdot}8$ and $R=0{\cdot}2$, the proportions of the genotypes would be $DD=0{\cdot}64$, $DR=0{\cdot}32$ and $RR=0{\cdot}04$. In this population the lowest possible incidence of left handedness would be 4 per cent. The incidence could rise to 36 per cent if there were full expression of *R* in heterozygotes, but this would be extremely unlikely in a normal population. The degree of expression may be influenced by many factors including age, sex and defects of the central nervous system. Assuming a degree of expression of 25 per cent so that 1/4 of heterozygotes are called left handed, the expected proportions of left-handed offspring of the three possible matings are close to those observed in three studies of familial handedness[3]. These results could be interpreted as consistent with other models of the inheritance of handedness ; the special advantages of the present model can be appreciated through its application to the problems discussed here.

Direction of Shifts of Cerebral Dominance in Heterozygotes. Annett, Lee and Ounsted[4] suggested that children with unilateral electroencephalographic foci and mixed hand preferences tend to locate verbal functions in the hemisphere with the focus so that biologically more primary

skills of orientation in space can be developed in the opposite normal hemisphere. The possibility that, given one intact hemisphere and the alternative of using it for either speech or visuo-spatial functions, speech would be allowed to suffer, is strongly supported by the data of McFie[5] for children who suffered early unilateral brain injuries and afterwards underwent hemispherectomy. The majority of these children showed greater verbal than non-verbal impairments. It is also supported by Naidoo's finding cited in ref. 6 that apparently healthy children of mixed handedness were significantly inferior to matched consistent handers, both right and left, on tests of verbal intelligence. There are strong grounds for believing therefore that in some circumstances heterozygotes may shift cerebral functions at the expense of speech.

The identification of the factors which lead some heterozygotes to shift speech into the damaged hemisphere while some clearly do not awaits investigation. Annett *et al.*[4] suggested that only injuries sustained in early childhood would result in such shifts. There is a series of adults, however, with epileptogenic unilateral anomalies in whom paroxysmal dysphasia is associated with lesions of either hemisphere[7]. These patients, and those of Annett *et al.* and McFie, suffered chronic disruptions of cortical function. It is possible therefore that speech functions are transferred to the damaged hemisphere when the maintenance as well as the development of visuo-spatial skills is threatened by a persistent cortical malfunction. Acute injuries to otherwise healthy adult brains show no excess of left handers with aphasia[8].

Applications of the Model. (1) *Left handedness in normal populations.* There are several differences of opinion as to the nature of left handedness and the status of ambidexters[9,10]. The present model has three contributions to make : (*a*) It accounts for the finding that many people who regard themselves as left handed are in fact less consistent users of the left hand than the majority of right handers of the right[11]. But some left handers use the left consistently. The existence of two sorts of left hander is an essential feature of the present model, inconsistent ones being heterozygotes and consistent ones recessive homozygotes. (*b*) The well-documented decline in the incidence of left handedness with increasing age[12] is accounted for by supposing that the dominant gene increases its control during growth. (*c*) The cultural and environmental pressures usually said to induce left handers to use the right hand can be envisaged as operating in the context of a hereditary predisposition to develop the use of either hand. Without the concept of partial penetrance of the recessive gene in heterozygotes, Trankell[3] is forced to suppose that recessive homozygotes may develop right handedness in the absence of any genetic predisposition to the use of the right hand. If homozygotes can be induced to shift through cultural pressures, explanation must then be sought for the existence of a small group of intractable sinistrals which seems to have persisted, as Brain reminds us, at least since the army of the Children of Benjamin assembled (*Judges*, 20).

(2) *Left handedness in abnormal populations.* Attempts to explain the raised incidence of left handedness among the defective, the epileptic and those with langauge disorders are attended by many difficulties, not the least of these being the fact that the majority of all such cases are consistently right handed.

The present model supposes that consistent handers will suffer defects of development according to the site and severity of cerebral damage. Heterozygotes, however, have some ability to compensate for such damage by shifting dominance. The raised incidence of left handedness in these pathological groups is the result of such attempts to compensate. If it is the case, as hypothesized, that language functions tend to be shifted to the damaged side, there is no need to look for further explanation of the raised incidence of mixed and left handedness among the speech disordered or of the typically lower verbal than non-verbal intelligence quotients of the intellectually subnormal.

(3) *Probability of aphasia in left handed adults.* The facts and theories advanced to explain them are carefully analysed by Zangwill[6,13]. The present model suggests that the major differences of opinion are probably due to differences in the cases considered.

Hughlings Jackson's view that the leading hemisphere is usually contralateral to the preferred hand is probably true of consistent handers both right and left. But many people who regard themselves as left handed are in fact inconsistent. Zangwill[13] found only 15 cases in the literature of aphasia in sinistrals who are recorded as writing with the left hand. If the majority of left handers cited in the literature are in fact heterozygotes in whom a dominant gene has directed speech into the left hemisphere, it is not surprising that many have concluded that handedness and cerebral dominance are unrelated ; that the left hemisphere leads irrespective of handedness. But there are undoubted cases of aphasia resulting from lesions of the right hemisphere and in such cases it is almost always possible to find sinistral tendencies in the patient or his kin.

Regarding the probabilities that the left or the right hemisphere leads in sinistrals, Bingley's[9] analysis suggests that the chances are equal that speech will be placed in either hemisphere. If consistent and inconsistent left handers are differentiated it should be possible to improve this 50/50 prediction.

The arguments for the hypothesis of bilateral representation of speech in left handers seem to rest on cases which may have suffered early injuries or have injuries with chronic effects. The hypothesis that such cases shift speech into the damaged hemisphere is probably sufficient to account for the excess of left-handed aphasics with injuries on either side.

(4) *Probability of recovery from aphasia.* Finally, the present model explains the data on remission of aphasia[13]. It seems clear that the chances of recovery following acute lesions in adulthood are greater for sinistrals than dextrals ; the chances of recovery are also greater for dextrals with left-handed kin than dextrals without such kin. Left handers and right handers with sinistral relatives are more likely to be heterozygotes than dextrals of dextral stock. An important factor in the recovery from aphasia would seem to be the possession of the alternative gene which allows speech functions to be developed in the alternative hemisphere.

Tests of the Model. These will be readily made when there are three sets of information available for groups of patients. First, the presence of unilateral lesions differentiated according to probable age of occurrence and the relative transience or persistence of their effects ; second, the results of psychological tests of verbal and non-verbal abilities ; and third, the laterality of patients and their kin.

I thank Dr. J. A. Fraser Roberts and Dr. C. O. Carter for their advice. They do not necessarily accept the present formulation.

ASTROPHYSICS

A New Model of Solar Flares

THE extensive observational results and theoretical investigations of solar flares have recently been compiled in refs. 1 and 2. Most models of solar flares have assumed that the only reasonable mechanism for energy storage is that of magnetic field. Parker[3] has recently criticized these theories and shown, in particular, that they do not explain the rapidity (10^2 sec) of the flash phase.

There is a more general argument for rejecting all theories which assume that the stored energy is purely magnetic, being derived from sub-photospheric fields and propagating as the Poynting flux of slowly varying force-free configurations. Such theories require specific changes in the structure of the magnetic field at the photosphere, such as the twisting of flux tubes or the movements of sunspots towards each other. However, the phenomenon of homologous flares[4] indicates that a sequence of flares can occur when the magnetic field at the photosphere (which must provide the 'blueprint' for the flares) is unchanged.

If we may not invoke changes in the photospheric magnetic field to provide the stored energy released in a flare, it is necessary to find some other mechanism for extracting energy from within the photosphere and storing it above the photosphere. de Jager[5] has emphasized that one of the most striking characteristics of flares is the anomalously high density of the gas involved, and this suggests that one consider gravitational potential energy as an alternative or complementary form of storage of energy.

This chain of thought suggests that one visualize the pre-flare configuration as a dense layer of cool gas supported by and compressing a magnetic field. We might then explain homologous flares by proposing a mechanism for the slow build-up of such a configuration, which will at some stage become unstable. The instability, which will be identified as the flash phase of a flare, must be such as to allow the magnetic field to return to its unstressed state.

The build-up of the proposed pre-flare configuration must involve the circulation of gas in the chromosphere and perhaps involve circulation also in the corona. There is observational evidence that such circulation occurs in centres of activity[6] and that such circulation is closely related to flare activity[7]. It is possible that such a circulation of gas above the photosphere is the visible consequence of a primary circulation pattern below the photosphere. This interpretation would make it unnecessary to make further enquiry into the adequacy of the power supply.

There is, however, an alternative possibility. The growth of the pre-flare configuration can best be understood as the result of condensation of gas in the chromosphere. This implies that the source of power necessary to feed the flare storage system is one which heats the gas and, because of subsequent condensation, leads to circulation.

In order to show how this may come about, we should recall that, on magnetically 'quiet' parts of the Sun's surface, there is a flux of non-thermal energy, which we believe to be predominantly acoustic in form[8], which heats the chromosphere and corona above the photospheric temperature and thereby drives the solar wind. At a bipolar or complex spot group, gas which is heated by non-thermal means can rise only to heights permitted by the magnetic-field configuration and may afterwards cool by radiation. This heating-condensation sequence may lead to a circulation pattern in which gas is pumped up in one region and descends in another. The magnetic field of a sunspot should provide a channel for such downward flow, and one may argue[9] that the Evershed effect provides evidence that this is the case. The mass flow at a large sunspot is about 10^{19} g/day.

One would not expect that all the gas heated by non-thermal energy would circulate in a steady pattern. If the magnetic field lines anywhere form a 'trough', gas will tend to condense in this region and the consequent buckling and sagging of field lines will provide an even more effective 'cold trap'. As gas continually condenses, the magnetic field will be compressed so as to maintain a balance of forces. Provided the magnetic field has non-zero shear (and this must in general be the case), this process, which represents the storage of energy in both magnetic and gravitational forms, will continue until the plasma-field configuration becomes unstable. The relevant instability[10] is resistive and therefore allows the mass to fall to the photosphere and the magnetic field to rise into the corona.

The energy of a class 3+ flare is 10^{32} ergs, and it is known from observation of homologous sequences[4] that this is accumulated in about one day (10^5 sec). The observed area of such a flare is 10^{20} cm^2, but one might expect that the non-thermal energy is drawn from a somewhat larger area, say, 10^{21} cm^2. It is therefore necessary to convert into stored energy 10^8 ergs cm^{-2} sec^{-1}. Since Osterbrock[11] has estimated the total non-thermal energy flux into the chromosphere to be 10^7 ergs cm^{-2} sec^{-1} over quiet regions of the Sun's surface, and since the non-thermal energy flux is believed to be higher over magnetically active regions (as evidenced by the increased density and temperature of the chromosphere), we require that only a small fraction of this energy supply be stored in the pre-flare configuration.

If we further suppose that the mass condensed is comparable with that collected by a sunspot in one day, 10^{19} g, we are led to construct a field-plasma configuration, of area 10^{20} cm^2, with graduated density and magnetic field strength, the maximum values being $10^{11.3}$ cm^{-3} and $10^{2.5}$ gauss and, in consequence, the scale height being $10^{8.5}$ cm. The magnetic flux trapped in this way is about 10^{21} gauss cm^2, comparable with the flux of a sunspot.

The characteristic growth time of this instability[10] is the time of propagation of an Alfvén wave across the layer which, for the model quoted, is about 10^2 sec, in agreement with observation of the flash phase of a solar flare. If a large fraction of the stored energy is dissipated as Joule heating of the initially overlying mass of gas, the temperature rise will be a few thousand degrees, in agreement with observation. One would expect that a small upper layer, more tenuous than the bulk of the gas and overlying more magnetic flux, will be heated to considerably higher temperatures, perhaps 10^5 deg. or 10^6 deg. The conductivity would then be so high that the resistive decoupling of the motions of particles and field lines will fail to operate and the gas will be swept along with the magnetic field. It would not be visible in $H\alpha$ until, in a time of order 10^3 sec, it has cooled to a temperature of order 10^4 deg., by which time the magnetic field will have relaxed to its current-free state, forming arches extending into the corona. The visible manifestation of this stage of the flare process would be the appearance of a large mass of gas in the corona, which then streams down along the magnetic field lines. We offer this mechanism as an interpretation of the observations of Kleczek[12]. Kleczek's

estimate of the mass involved is 10^{16} g, which represents only 10^{-3} of the total mass involved in the pre-flare configuration.

Although the primary instability does not produce oscillatory electromagnetic fields, it is to be expected that the instability will generate turbulent magneto-hydrodynamic motion which can drive many types of plasma waves. Waves with frequency spectra covering the ion and electron gyrofrequencies will lead to stochastic acceleration as has been noted in a different context by Stix[13]. High-energy protons and electrons are known to be produced by solar flares, the latter causing certain types of radio bursts.

Spectrum and Relative Intensities of Interstellar OH Lines

The initial detection of the OH lines in the interstellar medium involved the two strongest lines at 1,665·402 Mc/s and 1,667·357 Mc/s of the four hyperfine lines making up the $^2\Pi_{3/2}$, $J=3/2$, Λ-doublet[1]. Subsequent observations resulted in the detection of the two weaker lines at 1,612·201 Mc/s and 1,720·559 Mc/s[2]. The strong OH absorption in the direction of the galactic centres, noted by the Australian workers[3], and the unexpected disagreement between the theoretical and observed intensity ratios of the lines[2], make it important to consider the detection possibilities of other radio lines of OH in the interstellar medium. A discussion of molecular energy-levels and the physical mechanism responsible for the Λ-doublet levels of OH has been prepared for publication elsewhere[4]; but here we wish to direct attention to 14 microwave lines of various energy-levels and isotopic species of OH, some of which appear to be capable of detection at the present time. The line frequencies, theoretical relative intensities, and transition probabilities are presented in Table 1. The frequencies have been computed by using the theory of Dousmanis, Sanders, and Townes[5], and the hyperfine coupling constants given by Radford[6]. The dipole moment for all isotopic species has been taken to be $(1{\cdot}60\pm0{\cdot}12)\times10^{-18}$ e.s.u., although this was determined only for $^{16}O^1H$ (ref. 7).

The lines given in Table 1 arise from the ground levels of $^{16}O^2H$, $^{18}O^1H$, and the ground and excited states of $^{16}O^1H$. Detection of the $^{16}O^2H$ lines does not appear to be very probable, because of the upper limit of 1/13,000 for the $^2H/^1H$ abundance ratio in the direction of Cassiopeia *A* (ref. 8), therefore only the strong $\Delta F=0$ lines are presented. The OH/H abundance ratio, however, varies

Table 1. Computed Frequencies of OH Λ-Doublet Transitions, including Hyperfine Structure, for Various States and Isotopic Species

Isotopic species	State	Transition $j\rightarrow i$	Frequency (Mc/s)	Relative intensity	$A_{i\rightarrow j}$ (sec^{-1})
$^{16}O^1H$	$^2\Pi_{3/2}$, $J=3/2$	$F=2\rightarrow1$	1,612·201 ± 0·017	1	$4{\cdot}50\times10^{-12}$
		$F=1\rightarrow1$	1,665·402 ± 0·007	5	$2{\cdot}47\times10^{-11}$
		$F=2\rightarrow2$	1,667·357 ± 0·007	9	$2{\cdot}66\times10^{-11}$
		$F=1\rightarrow2$	1,720·559 ± 0·024	1	$3{\cdot}24\times10^{-12}$
	$^2\Pi_{3/2}$, $J=5/2$	$F=3\rightarrow2$	6,017·2 ± 1·0	1	$4{\cdot}17\times10^{-11}$
		$F=2\rightarrow2$	6,031·2 ± 1·0	14	$5{\cdot}92\times10^{-10}$
		$F=3\rightarrow3$	6,035·2 ± 1·0	20	$6{\cdot}03\times10^{-10}$
		$F=2\rightarrow3$	6,049·1 ± 1·0	1	$3{\cdot}03\times10^{-11}$
	$^2\Pi_{1/2}$, $J=1/2$	$F=1\rightarrow0$	4,699 ± 4·0	1	$2{\cdot}56\times10^{-10}$
		$F=1\rightarrow1$	4,717 ± 4·0	2	$1{\cdot}73\times10^{-10}$
		$F=0\rightarrow1$	4,810 ± 4·0	1	$9{\cdot}10\times10^{-11}$
$^{16}O^2H$	$^2\Pi_{3/2}$, $J=3/2$	$F=5/2\rightarrow5/2$	310·24 ± 0·10	10	$1{\cdot}32\times10^{-13}$
		$F=3/2\rightarrow3/2$	310·06 ± 0·10	4·3	$8{\cdot}45\times10^{-14}$
		$F=1/2\rightarrow1/2$	309·97 ± 0·10	2·2	$8{\cdot}74\times10^{-14}$
$^{18}O^1H$	$^2\Pi_{3/2}$, $J=3/2$	$F=2\rightarrow1$	1,584·3 ± 0·2	1	$4{\cdot}30\times10^{-12}$
		$F=1\rightarrow1$	1,637·3 ± 0·2	5	$2{\cdot}36\times10^{-11}$
		$F=2\rightarrow2$	1,639·3 ± 0·2	9	$2{\cdot}54\times10^{-11}$
		$F=1\rightarrow2$	1,692·3 ± 0·2	1	$3{\cdot}10\times10^{-12}$

by a factor of ~1,000 between the directions of Cassiopeia *A* and the galactic centre[1,3], hence large spatial variation in the $^2H/^1H$ abundance ratio might also exist. The lines of $^{18}O^1H$ are particularly interesting. If the terrestrial $^{18}O/^{16}O$ abundance ratio of 1/490 holds throughout the galaxy, then an optical depth of $\sim2\times10^{-3}$ can be expected for the +40 km/s component of OH absorption in the galactic centre. This would give an absorption of ~0·5° K for the 210-ft. radio telescope at Parkes. A further consideration of the $^{18}O^1H$ lines is that their frequencies are sufficiently close to the $^{16}O^1H$ lines that new equipment is not needed. The frequencies of the first two excited states of $^{16}O^1H$ are also given in Table 1. Because of radiative decay to the ground-state, detection of these lines is less probable but the population of these levels could be drastically influenced either by the infrared radiation field or the method of production of OH in the interstellar medium.

An unexpected result of the astronomical OH observations is that the intensities of the four $^2\Pi_{3/2}$, $J=3/2$ lines are in the ratios 1 : 2·2 : 2·7 : 1, whereas the theoretical values are 1 : 5 : 9 : 1[2]. A possible explanation is the existence of many small condensations of large optical depth[2,3], but very special velocity and spatial distributions are needed to explain the entire observed profile. The OH observations have been interpreted by using the radiation theory developed by Milne[9] as modified by Wild[10] for the radio domain; but this theory may be inappropriate when the distance between absorbers is large compared with a wave-length and the radiation field is non-isotropic. Milne, and consequently Wild, considered isotropic radiation in the derivation of the optical depth and no account was taken of the possibility of atomic (or molecular) resonant coherent scattering[11]. If it is assumed that α is the fraction of the cross-section for resonant scattering out of the beam, then the optical depth τ and volume emissivity η can be written as:

$$\tau=\tau_0\left(1+2\alpha\frac{kT_s}{h\nu}\right),\qquad \eta=\eta_0\left(1+2\alpha\frac{kT_r}{h\nu}\right),$$

where τ_0 and η_0 are the values for the case of no scattering, and T_s and T_r are the excitation and radiation temperatures, respectively. The scattering parameter α is a function of the density of scatterers and the transition probability of the line and, therefore, will be different for each line. It follows that the ratio of intensities of the OH lines will be in disagreement with the ratios computed with scattering neglected. Furthermore, since α is a function of the position of the gas cloud relative to the continuum radio source, α may vary within the galaxy, and the line intensity ratios will vary accordingly. Note, also, that for T_s of the order of 1° K the optical depth may be as much as an order of magnitude greater than previously supposed. This may have a consequence for the problem of detecting weak radio lines, such as $^{18}O^1H$. To the extent that the radiation field is non-isotropic in inter-

galactic space, the scattering effect may force a reinterpretation of attempts to detect the intergalactic medium by a 21-cm absorption[12,13].

RADIO ASTRONOMY

Rotation Rate of Venus measured by Radar Observations, 1964

During the June 19, 1964, close approach of Venus, radar observations at 410·25 Mc/s were made using the 250-ft. *Mark I* radio telescope at Jodrell Bank. Echoes were first obtained at full strength on June 5 and continued at intervals until July 26. The equipment[1] was basically that used in 1962: a C.W. radar system in which the quantities measured were the doppler shift and the frequency spectrum of the returned signal. Modifications to the receiver, including the use of a parametric amplifier, improved the signal-to-noise ratio to give a radio frequency signal to noise at closest approach of about 0·5. Again the spectral analysis was made with a multi-channel real-time integration system, having eleven channels in frequency each approximately 1 c/s wide spaced 1 c/s apart. As in 1962, the spectrum was very narrow, most of the energy being in one channel. Owing to the improved signal-to-noise ratio, however, significant rises were obtained in at least two channels on each side of the centre. Examples of the channel readings for June 17 and July 14 are shown in Fig. 1. These have been corrected for a 10 per cent bias by integrations of noise to determine correction factors.

The significant rises obtained in the channels on each side of the centre channel have enabled the methods previously described[1] to be applied to estimate the half-power width of the central feature of the spectrum. This was found to be a function of time, changing from below 1 c/s at closest approach to about 1·5 c/s 35 days later. This effect can be seen in Fig. 1 quite clearly. Measured values are plotted in Fig. 2.

It is not possible to calculate directly the apparent rotation rate of Venus from these observations, as the ratio of the width of the central feature measured to the total limb-to-limb width of the spectrum is unknown. However, the points may be normalized to unity at closest approach and the shape of the resultant curve compared with that expected for various values of the intrinsic rotation. This problem has been discussed by several workers[1–3]. The apparent rotation is made up of two components: (*a*) the intrinsic rotation relative to inertial space; (*b*) the apparent rotation rate caused by the relative motion of Venus with respect to the observer.

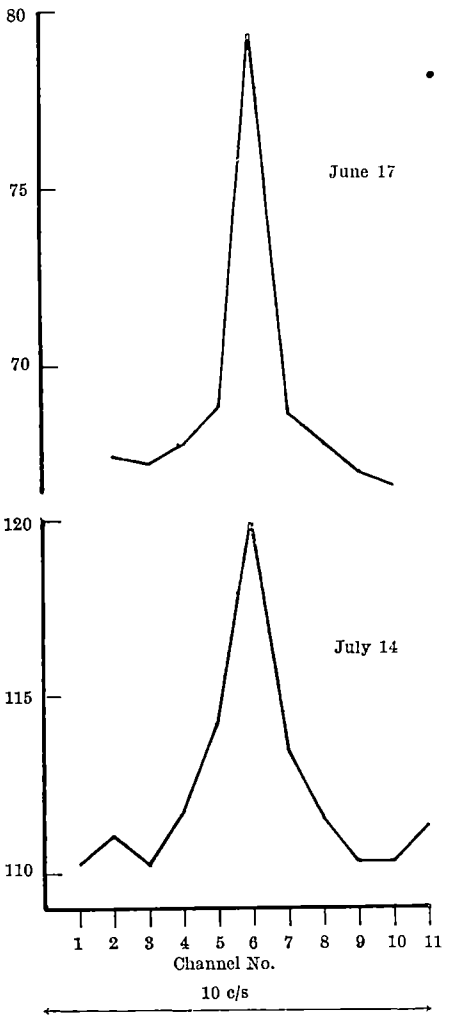

Fig. 1. Plots of the corrected integrator channel readings for June 17 (almost closest approach) and July 14 (25 days from closest approach). The increased width of the spectrum can be seen. The channels are spaced at 0·954 c/s so the abscissæ cover about 10 c/s. The ordinates are in arbitrary units from the integrating system. On June 17 the integration time was 162 min and on July 14 it was 214 min

This latter component is time variable, rising from zero at about ± 21 days to more than 10^{-7} rad/sec direct at closest approach. The intrinsic rotation, if the axis is perpendicular to the plane of the ecliptic, simply adds to this if direct, or subtracts from it if retrograde. Thus direct intrinsic rotation will give a maximum of apparent rotation at closest approach and retrograde intrinsic rotation (if greater than about 10^{-7} rad/sec) will give a minimum.

Clearly the measured points in Fig. 2 show a minimum rather than a maximum at closest approach, indicating retrograde rotation. This is in broad agreement with the results obtained in 1962 by Rzhiga[4] in the U.S.S.R. and by Carpenter[5] at the Jet Propulsion Laboratories in the United States. These workers, using a similar method, arrived at a period of 250–300 days retrograde.

The curves shown in Fig. 2 are calculated on the assumption of co-planar circular orbits and a rotation axis perpendicular to the orbital plane, and are normalized to unity at closest approach. The measured points do not fit any curve well, but a period of about 100 days retrograde is the minimum period they would reasonably allow. However, systematic effects such as the size of the discrete steps used in doppler removal (about 0·1 c/s) will

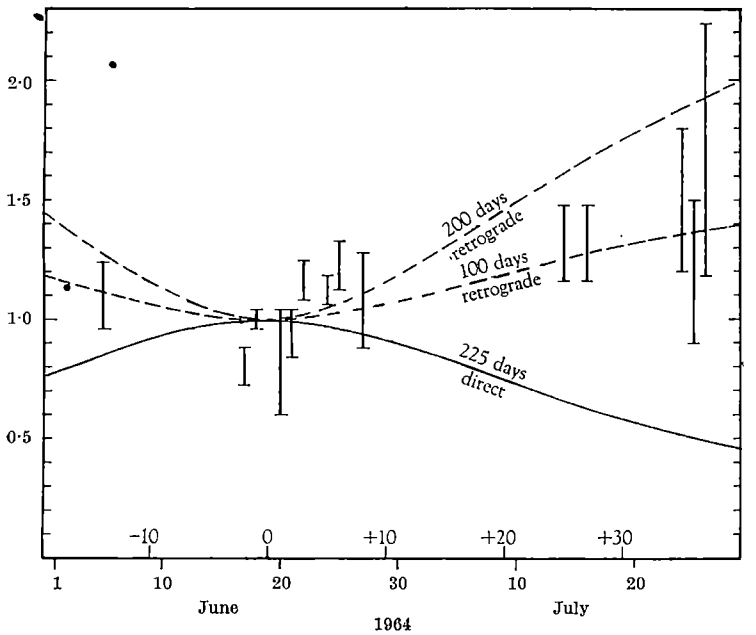

Fig. 2. Measured width to 3 db points of the central feature of the spectrum as a function of time. The lower abscissæ scale is date; upper abscissæ scale is days from closest approach. The ordinate is in units of channel width (1 unit = 0·954 c/s). Dotted curves are variations expected for 100 and 200 days retrograde rotation, normalized to unity at closest approach. The full curve shows similarly the variation expected for 225 days direct, corresponding to Venus always turning the same face towards the Sun

tend to broaden the spectrum and make the minimum of Fig. 2 more shallow. Thus any rotation rate derived by strict curve fitting is likely to be too small. If it is assumed that the central feature of the spectrum has been systematically broadened by 0·2 c/s, a rather similar fit is obtained with the 300-day curve. Hence our results confirm that the rotation is retrograde but can only indicate that the period is between 100 and 300 days. Similar curves can be calculated for various directions of the rotation axis, but the accuracy of the present work does not justify this.

It is hoped that further analysis by digital computer of the recorded returned signals will provide more accurate spectra; this may make further analysis profitable.

The data for the ephemeris were provided by the Royal Greenwich Observatory, Herstmonceux, and by the U.S. Ephemeris Office, and we thank G. Walker and R. A. Porter, who assisted with the observations.

Inverse Compton Effect as a Possible Cause of the X-Ray Radiation of Solar Flares

Shklovsky[1] has suggested the inverse Compton effect as a possible cause of the solar flare-burst emission of hard X-ray photons. This process, as its name implies, involves a scattering interaction between a relativistic electron and a low-energy photon. The interaction produces an X-ray photon and the electron loses a corresponding amount of its energy. The X-ray photon production rate from this process is directly proportional to the density of ambient photons, the density of energetic electrons and the square of the electron energy. Using a radiation density which is twice the photospheric value, he estimates that it is possible to account for the observed flare-burst X-ray emission in the 1–100 keV region if the total energy of 10–100 MeV electrons in a flare is of the order of 10^{30} ergs.

Shklovsky also suggests that observations of the synchrotron emission from this hypothesized electron cloud in the millimetre and far infra-red would prove or disprove its existence. I wish to point out that observations are already in hand which indicate that this is not an important X-ray generating mechanism in the solar case. These are the existing observations of hard X-rays from solar flares.

We have computed the bremsstrahlung to be expected from the hypothesized cloud of strongly relativistic electrons which are required to produce the inverse Compton photons. The bremsstrahlung cross-section formulæ collected by Koch and Motz[2] were used (their equations $3BS[a]$, $3BS[c]$ and $3BS[d]$). We have assumed an atmosphere of neutral hydrogen, and these formulæ take account of nuclear screening by bound electrons. If the hydrogen were ionized the bremsstrahlung cross-section would be larger by less than a factor of two.

For electron energies, E_e, in the range 10–100 MeV in a neutral hydrogen gas and for emitted photon energies, k, such that:

$$k < 0{\cdot}1\, E_e \qquad (1)$$

the bremsstrahlung cross-section is, to a good approximation:

$$\mathrm{d}\sigma_k = 1{\cdot}6 \times 10^{-26} \frac{\mathrm{d}k}{k}\ \mathrm{cm}^2 \qquad (2)$$

The X-ray photon flux at the Earth in the spectral interval (k_0,k) from the radiating volume, V, is given by the expression:

$$F_{ph}(k_0,k) = \frac{N_H N_e^* V v_e}{4\pi\,(\text{A.U.})^2} \int_{k_0}^{k} \mathrm{d}\sigma_k \text{ photons cm}^{-2}\text{ sec}^{-1} \qquad (3)$$

N_e^* is the density of the relativistic electrons, N_H is the density of hydrogen atoms and/or ions, v_e is the velocity of the relativistic electrons (substantially equal to the velocity of light) and A.U. is the astronomical unit ($1{\cdot}5 \times 10^{13}$ cm). Evaluating the constants and performing the integration yields the expression for the photon flux at the top of the atmosphere:

$$F_{ph}(k_0,k) = 1{\cdot}7 \times 10^{-43} N_H N_e^* V(\ln k - \ln k_0) \qquad (4)$$

Using Shklovsky's values for N_H ($\approx 10^{11}$ cm^{-3}, this value is required to limit the duration of the burst by collisional losses), and $N_e^* V$ ($\approx 10^{34}$, that is, 10^{30} ergs of 50 MeV electrons) we compare the computed bremsstrahlung photon flux at the top of the atmosphere in the 20–50 keV and 50–150 keV spectral intervals with that reported by Anderson and Winckler[3] for the great solar flare of September 28, 1961.

	Bremsstrahlung (this communication)	Anderson and Winckler (peak of flare burst)
$F_{ph}(20, 50)$	190	≈ 100
$F_{ph}(50, 150)$	230	≈ 6

It is immediately clear that the flux of photons of $k > 50$ keV from the bremsstrahlung of the strongly relativistic electrons is proportionately much greater than

that observed by Anderson and Winckler. Even the very energetic solar X-ray event reported by Peterson and Winckler[4] appeared to fall off much more sharply beyond 500 keV than would have been possible if there had been a significant contribution from inverse Compton photons.

It may be argued that a careful choice of parameters would overcome the foregoing discrepancy. Our computations indicate, however, that any cloud of energetic electrons which can produce a measurable contribution of inverse Compton photons of the observed duration will always produce a greater flux of high-energy bremsstrahlung photons than has been observed.

GEOPHYSICS

Model Studies of Elastic Wave Propagations in Crustal Blocks under Tectonic Stresses

ALTHOUGH the existence of tectonic stresses is known, so far no practical method has been discovered to locate and determine the magnitude of these stresses. In this communication a technique is discussed which may be utilized to detect the tectonic stresses.

Experimental evidence indicates that the velocity of elastic body waves in rocks is a function of the compressive stress along the direction of propagation[1–7]. If a crustal block is under tectonic forces, the velocity of elastic waves in such a block would be affected by these forces. Consequently, a change in velocity in a particular area as a function of direction could arise from an inhomogeneous stress field within that region. The blocks which are under gravitational forces alone have a relatively simple stress distribution. These are termed the quiet blocks, and those which are also under tectonic forces are called the active blocks.

Using the velocity pressure data of Birch[8] for P-waves and Simmon[9] for shear waves for Westerly granite, two distinct models are investigated adopting different values of Poisson's ratio. The first model is a quiet block. The ray path of elastic waves is determined for this model and the time–distance curves are computed, using the $B5000$ digital computer. In all cases, I find that the refracted energy propagates up to a critical distance X_c and the wavefront then swings back; the refracted energy from deeper horizons arrives at the surface at distances smaller than the critical distance X_c.

The second model is an active block of granite in equilibrium with some external tectonic forces. The travel–time curves for the active block are asymmetric. The circular symmetric travel times for the quiet block degenerate into an ellipse for a block which is under tectonic stresses.

Table 1

Velocity (km/sec)	Pressure (atm.) 0	10	500	1,000	2,000	4,000	6,000	10,000
P-waves	—	4·10	5·63	5·84	5·97	6·10	6·16	6·23
S-waves	2·77	—	3·27	3·36	3·44	3·51	3·54	3·58

In this investigation I used the velocity pressure data of Birch[8] and Simmon[9] for Westerly granite reproduced in Table 1. These velocity data are expressed empirically as:

$$V = V_0 + A_1\sigma + A_2\sigma^2 + A_3\sigma^3 + A_4\sigma^4 + \qquad (1)$$

where A_1's are coefficients and σ is the stress along the direction of propagation. If we assume that lateral deformation within the block is prevented, then the stress tensor for such an isotropic quiet block is described as:

$$S_q = \begin{bmatrix} \frac{\nu\sigma_z}{1-\nu} & 0 & 0 \\ 0 & \frac{\nu\sigma_z}{1-\nu} & 0 \\ 0 & 0 & \sigma_z \end{bmatrix} \qquad (2)$$

where the vertical stress σ_z is given by: $\sigma_z = \rho g z$; ρ, average density of the material; g, gravitational acceleration ; z, depth ; ν, Poisson's ratio. In general, the stress σ in any arbitrary direction in the xz plane may be described as:

$$\sigma = \sigma_x l^2 + \sigma_z(1 - l^2) + 2l(1 - l^2)^{1/2}\tau_{xz} \qquad (3)$$

where l is the direction cosine. In the case of the quiet block, $\tau_{xz} = 0$. Once σ is computed for an initial direction cosine l, the velocity V can be determined from equation (1). Using Snell's law, the refraction of elastic energy is determined numerically. The travel time curves for P-waves propagating along a ray in the xz plane are given in Fig. 1. It is interesting to note that for the first model the energy for P-waves travels to a critical distance, $X_c = 137{\cdot}92$ km, and then the wavefront literally swings back. For the S-waves the critical distance $X_c = 165{\cdot}26$ km.

The stress tensor for an active block (the second model) is assumed to be:

$$S_a = \begin{bmatrix} (az + b + cx) & 0 & -ax - cz \\ 0 & \frac{\nu\sigma_z}{1-\nu} & 0 \\ -cz - ax & 0 & az \end{bmatrix} \qquad (4)$$

where b, 100 kg/cm²; c, 0·1 kg/cm²/m; a, 0·27 kg/cm²/m.

The travel-time curves for this model are asymmetric (Fig. 2); the circular symmetric travel-time on the arc of a circle for a quiet block degenerates into ellipses.

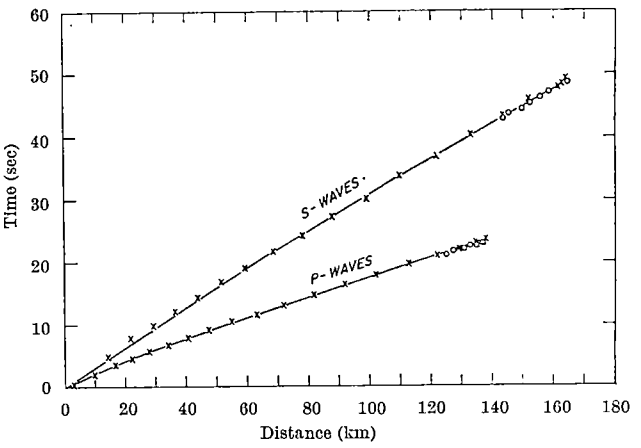

Fig. 1. Travel–time curves for elastic waves in model quiet block with Poisson's ratio = 0·35 (Birch and Simmon's data for Westerly granite). ×, Refractions from shallow horizons; ⊙, refractions from deeper horizons

The time difference involved for an active block was about 200 msec for the stations located over the arc of a circle with 5-km radius; the corresponding time difference for 6-km radius was about 300 msec (Fig. 2). Such a difference is easily observable in the field. In practice, however, the local geology and large-scale lithological variation within a block also give rise to variation of seismic wave velocity in different directions.

The idea deserves further theoretical investigation and extensive evaluation in the field. If successful, it will be a technique to determine the existence of tectonic stresses. By examining the time rate of change of velocities, it is conceivable that it may be possible to predict potential earthquake areas and thus prevent loss of life and property.

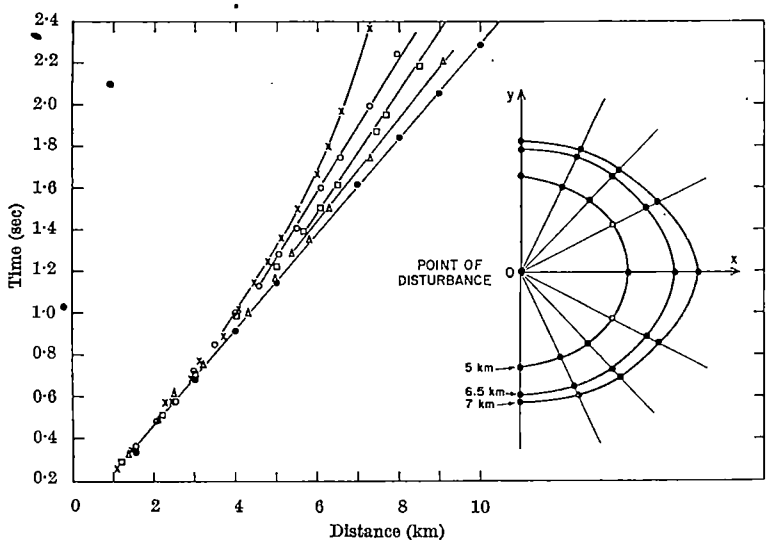

Fig. 2. Travel-time curves and distortion of these from circles to ellipses in an active block. ×, 0° x direction; ○, 30° from x axis; □, 45° from x axis; △, 60° from x axis; ●, 90° from x axis (y direction)

Palæomagnetic Results from Northern Canada suggesting a Tropical Proterozoic Climate

The Coppermine and September Mountains, in the north-central District of Mackenzie, Northwest Territories of Canada, are composed of a thick succession of tholeiite basalt flows. Directions of natural remanent magnetization were measured on 51 oriented samples from 24 sites (Fig. 1). The sites represent 24 of the more than 60 separate flows occurring in a vertical thickness of more than 5,000 ft. The flows dip from 0° to 5° north in the area sampled. Two potassium/argon whole rock age determinations on flow rocks, made in the Isotope and Nuclear Geology Section of the Geological Survey of Canada (Wanless, private communication), gave an average age of 1,150 m.y. with a probable error of ± 100 (calculated as two standard deviations from the mean). This places the age of extrusion of the flows in upper middle Proterozoic time. The lavas conformably overlie dolomite of the Hornby Bay Group, and in places thin sandstone bands are intercalated between the flows. A sample from a red sandstone intercalation gives a direction of $D = 236$, $I = +24$, which is similar to that of the flows.

Separate specimens from each sample were subjected to magnetic cleaning[1] and thermal cleaning[2] to reduce possible errors from secondary components. The precision parameter[3] of the natural remanent magnetization grouping ($k = 7$, $\alpha = 12$)° (Fig. 2a) was much improved after treatment in an alternating magnetic field of 75 œrsteds peak value ($k = 23$, $\alpha = 6$) (Fig. 2c). The direction after magnetic cleaning was 7° farther from the dipole field direction than that of the natural remanent magnetization. The scatter increased slightly ($k = 5$, $\alpha = 15$) in specimens heated to 480° C, and the resultant moved 13° away from the present field direction. This increase in scatter (Fig. 2b) may be due to the heating of about half the specimens above the Curie temperature of their dominant magnetic mineral. The differences between the mean directions of magnetization before treatment, after magnetic cleaning, and after thermal cleaning are not significant at $P = 0{\cdot}05$; but the fact that the cleaned directions are farther from the dipole field direction than before treatment suggests that a small viscous component in the direction of the dipole field has been removed.

Four specimens were heated to 625° C and cooled in a magnetic field of known direction and of intensity 1·3 œrsteds. The resulting thermoremanent magnetization direction was in each case within 2° of the direction of the field during cooling, showing that magnetic anisotropy does not affect the direction of thermoremanent magnetization in the specimens.

The laboratory tests support the idea that the natural remanent magnetization direction is that of the Earth's magnetic field at the time the lavas cooled. Furthermore, this direction is very close to that obtained in a preliminary investigation of gabbroic rocks of the nearby Muskox Intrusion (see Table 1), which has been assigned a radiogenic age of 1,150 m.y.[4] with a probable error of ±40 (calculated as two standard deviations from the mean).

The virtual geomagnetic pole position calculated from the mean direction of the flows (1° N., 176° W.), assuming that the dipole field hypothesis[5] is relevant to middle Proterozoic time, places the flows at a palæolatitude of 10°–15°, and suggests that the Hornby Bay Group with which they are associated was deposited under tropical

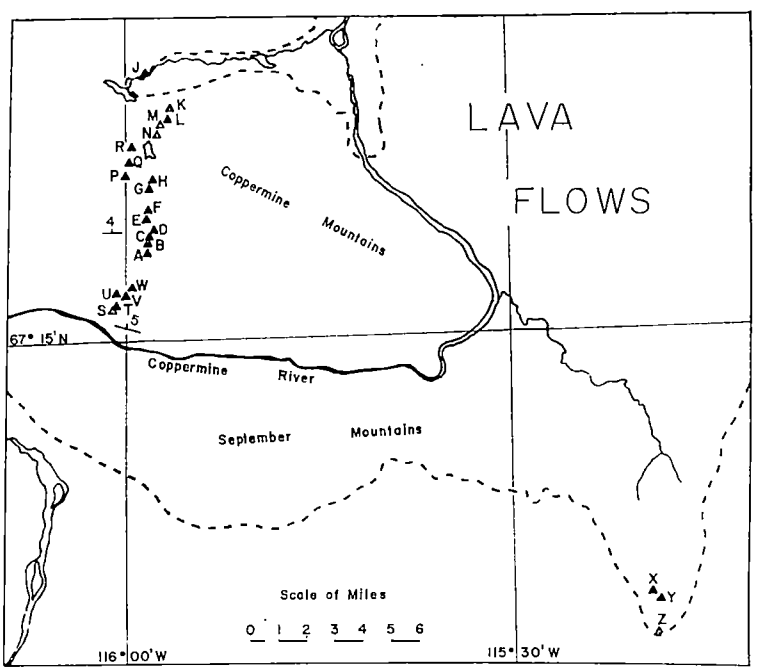

Fig. 1. A sketch map showing sampling sites

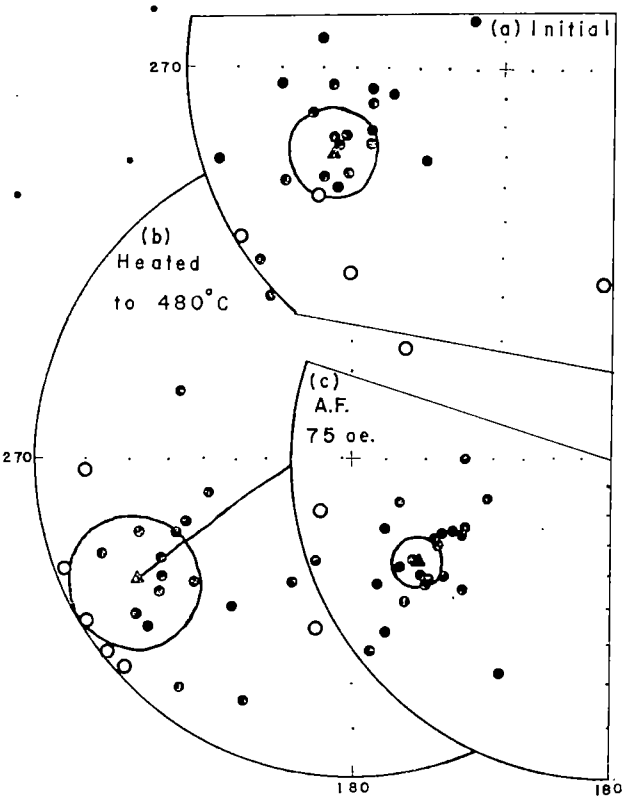

Fig. 2. Portions of stereographic nets showing mean site magnetization directions, (*a*) before treatment, (*b*) after heating to 480° C in a null magnetic field, (*c*) after treatment in an alternating magnetic field of 75 œrsteds peak value. North-seeking directions are plotted as open circles on the upper and dots on the lower hemisphere. Mean group directions, with the trace of the 95 per cent cone of confidence, are shown as triangles. The great circle between the heated mean and the dipole field direction is also shown

conditions. The occurrence of gypsum and anhydrite in the Minto Inlet Formation of Victoria Island, of late Pre-Cambrian age[6], is consistent with such a low latitude.

The close agreement of this pole position with those of comparable age from the Sudbury diabase dykes[7], the Duluth Gabbro[8], and the Muskox gabbroic rocks (Table 2), and the small polar errors ($d\chi = 7$, $d\psi = 4$) associated with the Coppermine lavas pole position, suggest that this virtual geomagnetic pole position may be used as an anchor for the North American polar wandering curve[8,9] for upper middle Proterozoic time.

Table 1. Coppermine Lava Flows and Muskox Gabbro Mean Directions and Statistics

Formation	Treatment	No. sites	No. samples	No. specimens	*D*	*I*	*R*	*k*	*α*
Coppermine lava flows	None	24	51	102	244	+29	20·88	7·4	12
,,	Alternating field of 75 œrsteds	24	48	48	242	+22	23·00	23	6
,,	Heated to 480° C	24	46	46	240	+15	19·11	4·7	15
Muskox gabbroic rocks	None	8	19	38	247	+33	7·48	13	16

PHYSICS

Meta-stable Ions in Double-focusing Mass Spectrometers

'Meta-stable peaks' are normally observed due to ions which dissociate near the entrance slit of the magnetic analyser in the sector mass spectrometer. In addition 'meta-stable peaks' due to ions which dissociate within the electrostatic analyser of a double-focusing mass spectrometer can also be observed and their position can be adjusted by varying the voltage across the electrostatic analyser.

Ions which dissociate during their transit of a mass spectrometer analyser tube are said to be meta-stable[1]. They are noted on the mass scale of the spectrum at a position corresponding to m^*, where:

$$m^* = \frac{m_2^2}{m_1}\left\{1 + \frac{(m_1 - m_2)(V - V_1)}{m_2 V}\right\}$$

and m_1 is the mass of the ion before dissociation, m_2 is the mass of the charged fragment after dissociation, V is the accelerating voltage and V_1 is the potential difference through which the ion of mass m_1 falls before decomposing[2]. In general, dissociation can occur anywhere between the ion source and the collector. There may also be a release of internal energy during the transition, so that conditions may be somewhat more complex than indicated by the above equation and many of the ions will not be recorded. A very small internal energy release will discriminate strongly against ions formed at large values of $(V - V_1)$ and prevent their passing through the entrance slit of the spectrometer at the end of the accelerating region. Owing to the directional focusing properties of the sector magnetic field, the decomposing ions most likely to be recorded, in a single-focusing mass spectrometer of the Nier design[3], are those that undergo decomposition near the entrance slit. In this case :

$$m^* \approx m_2^2/m_1$$

as is well known.

In the case of a double-focusing mass spectrometer of the Nier–Roberts geometry[4] it has been shown that meta-stable transitions occurring before entry into the electrostatic analyser can be observed by altering the accelerating voltage sufficiently to deflect the main ion beam such that it is no longer transmitted by the analyser[5]. Under such conditions the daughter ion of mass m_2 can, however, sometimes be detected. In the work recorded here it is shown that ions which dissociate during their transit of the electrostatic analyser tube can also be distinguished from ions that dissociate either before or after their passage of this part of the spectrometer tube.

If E is the voltage across the plates of the electrostatic analyser, then the ratio E/V can only be varied between comparatively narrow limits if ions are to be transmitted through this analyser. In the instrument used in this investigation, an A.E.I. double-focusing mass spectrometer type *MS*-9, it is possible to vary E/V by 1·3 per cent and still permit ions to pass through the analyser.

It has been noted that where meta-stable transitions involve only a comparatively small mass change as, for example, in the case of the transition noted in the spectrum of toluene :

$$\underset{(m/e\ 92)}{C_7H_8^+} \rightarrow \underset{(m/e\ 91)}{C_7H_7^+} + H$$

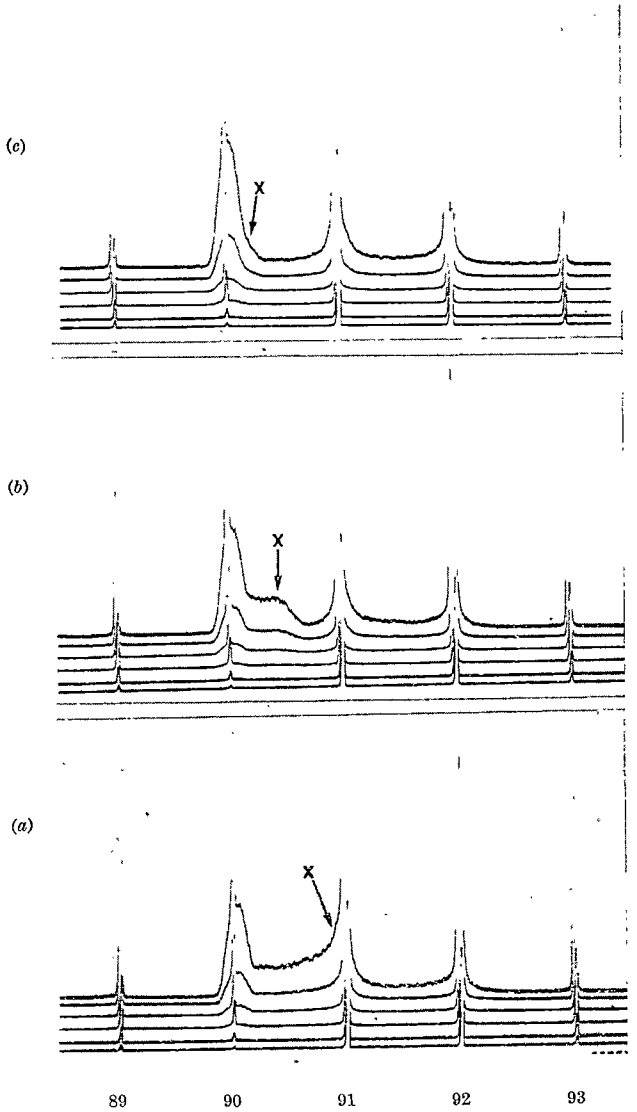

Fig. 1. Appearance of 'meta-stable peaks' in the spectrum of toluene, (*a*) $\Delta V/V = 0$, (*b*) $\Delta V/V$ = intermediate value, (*c*) $\Delta V/V \approx 1/91$

a peak can be observed due to transitions occurring within the electrostatic analyser, the position of which depends on the value of E/V. The 'meta-stable peak' corresponding to the above transition is shown in Fig. 1 at three different values of E/V. In each case it is possible to observe the 'normal meta-stable peak' at m/e 90·0 corresponding to a transition that occurs after the passage through the electrostatic analyser but before entering the magnetic analyser. In Fig. 1c it is seen that the peak corresponding to the electrostatic analyser transition, marked X in Fig. 1, merges into the peak from the 'normal' transition.

If the transition occurs at the entrance of the electrostatic analyser, the energy of an ion changes to

$$e\ V\ m_2/m_1 = e\ E\ r^1/2$$

where r^1 is the radius of curvature of the path of the ion of mass m_2

$$\therefore\ r^1 = 2\ V\ m_2/E\ m_1\ (< r)$$

where r is the radius of curvature of an ion passing centrally through the electrostatic analyser. To restore the ion of mass m_2 to its original path of radius of curvature r, the accelerating voltage V must be adjusted to $V + \Delta V$ (or E must be changed to $E - \Delta E$).

$$r = \frac{2(V + \Delta V)}{E} \cdot \frac{m_2}{m_1} = \frac{2\ V}{E}$$

from which it may be shown that :

$$(m_1 - m_2)\ V = m_2\ \Delta V$$

$$\text{or } \Delta V/V = m_1/m_2 - 1$$

If $m_1 \approx m_2$, as, for example, in the transition we have considered in toluene were $m_1 = 92$ and $m_2 = 91$, then :

$$\Delta V/V \approx \frac{1}{91}$$

Then depending on where the decomposition occurs :

$$0 < \Delta V/V < \frac{1}{91}$$

If the dissociation occurs after passage through the electrostatic analyser the peak occurs at mass 90 when $\Delta V/V = 0$. On the other hand, if the dissociation occurs before the ion enters the electrostatic analyser the peak occurs at mass 91 when $\Delta V/V = 1/91$.

Low-background Beta Counters for Iodine-131 Sources

In a recent article[1] the use of two end-window Geiger counters (20th Century Geiger-Müller type *EW*2C) for scanning chromatograms containing iodine-131 was discussed. It was shown that using anti-coincidence techniques the background in the double-counter system was typically about 3·5 c.p.m. Furthermore, it was pointed out that significant fraction of this background arose from radioactive contaminants in the window material of the counters. The efficiency of detection for iodine-131 and Whatman No. 1 chromatography paper is about 50 per cent. Using the formula quoted in ref. 1 the total time

(T) required to determine the presence of 2 μμc. with an accuracy of 10 per cent is 375 min. By carefully selecting Geiger counters, backgrounds lower than the typical one can be obtained, although it is doubtful if it is possible to do better than about 2·8 c.p.m. The above value of T would then be reduced to 316 min.

By special request, 20th Century Electronics have provided a slit-window Geiger counter in which the window, confined to an area of approximately 2·5 cm × 0·8 cm, is set into a metal base-plate. The dimensions of the counter are otherwise the same as the standard *EW2C* counter. The window area was chosen to be of a convenient size for scanning chromatograms. A double-counter system, with an anti-coincidence screen, made from these counters has a background of as low as about 1·5 c.p.m. Under these conditions the value of T, for 2 μμc. and 10 per cent accuracy, is reduced to 204 min. Apart from this reduction in counting time, use of counters of this type has the advantage that the chromatogram can be pulled through the arrangement in a stepwise fashion without the necessity of cutting the chromatogram up into individual sources.

Force associated with the Temperature Gradient on a Small Particle suspended in a Plasma

Mason and Chapman[1] have shown that the motion of small particles in a non-uniform un-ionized gas may be described through the Chapman–Enskog theory by treating the particles as large molecules. Their kinetic theory calculations agree with results obtained by previous investigators[2–4], who used free-molecule momentum transfer calculations, for all cases except when a temperature gradient is present.

For this case of a small particle in an un-ionized gas in a temperature gradient, it appears on experimental evidence[5] that the free-molecule momentum transfer calculations, which allow for inelastic collisions, provide a better description of the motion than the kinetic theory calculations[1] based on the elastically diffuse model.

It seems of value, then, to report the results of a free-molecule momentum transfer calculation of the force acting on a small suspended particle of a radius a in a plasma in which temperature gradients ∇T_i and a magnetic field of intensity $\vec{H}$ are present.

The assumption of free-molecule calculation is that the particle does not disturb the distribution functions of the surrounding fluid. Also in the calculation it is assumed that the radius of the suspended particle is much less than the radius of the Debye sphere; as a result of this assumption, collective effects of the plasma on the particle can be ignored[6]. A neutral, two-fluid model is assumed for the plasma; that is, the collisional coupling between the positive ions and electrons is considered unimportant.

The force acting on the particle is obtained by integrating the net momentum transferred over the particle surface S with normal $\vec{n}$.

$$\vec{F} = -\int_S \mathrm{d}S\vec{n} \cdot \sum_i \sum_{\pm} \int_{\pm} \vec{v}_i m_i \vec{v}_i f_i^{\pm} \, \mathrm{d}\vec{v}_i$$

and

$$\int_{\pm} \equiv \text{sign } (\vec{n} \cdot \vec{v}_i) \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} \int_{0}^{\text{sign } (\vec{n} \cdot \vec{v}_i)\infty}$$

The distribution functions f_i^- for this physical system are the first-approximation functions given by Chapman and Cowling[7]. The functions f_i^+ are defined by the surface momentum accommodation coefficients, α_i:

$$f_i^+ = \alpha_i f_i^{(0)+} + (1 - \alpha_i) f_i^-$$

where the $f_i^{(0)+}$ are the equilibrium distribution functions for species i leaving the particle surface.

The following expression for the thermal force acting on the suspended particle is obtained:

$$\vec{F} = -\left(\frac{4}{5}\right)a^2 \sum_i (2\pi k/m_i T_i)^{\frac{1}{2}} (\lambda_i/C_{vi}(1+\omega_i^2\tau_i^2)) (\nabla T_i - \omega_i \tau_i (\vec{H}/|\vec{H}|) X \nabla T_i)$$

where

$$\omega_i \tau_i = 3q_i |\vec{H}| / 5m_i C_{vi} p_i$$

and for species i in the plasma q_i is the charge, m_i the mass, λ_i the thermal conductivity, C_{vi} the specific heat at constant volume, p_i the pressure, and T_i the temperature.

Thus, in addition to a force acting on the particle in the direction of decreasing temperature, there is an additional force in the transverse direction. In the calculation of the transverse thermal force, just as for the thermal force, the terms involving the accommodation coefficients of the plasma species on the particle sum to zero over the surface of the sphere.

Of interest would be an experimental confirmation of the transverse thermal force. Further calculations are planned out of the free-molecule régime for a charged particle and a more realistic plasma model with both electric and magnetic fields.

CHEMISTRY

Electron Spin Resonance of β-Phenylhydroxylamino-β-methyl-pentane-δ-phenylimine Oxide

The compound formed by the oxidation of the condensation product of β-phenylhydroxylamine with acetone has been shown[1] to have the structure:

Electron spin resonance spectra of this compound have been obtained[2] and some[3] have shown a hyperfine structure consisting of 3 broad equal intensity lines 13 gauss apart, arising from the interaction of the unpaired electron with one of the ^{14}N nuclei. However, no hyperfine splitting due to the aromatic protons has been reported and it was decided to investigate any such structure. A

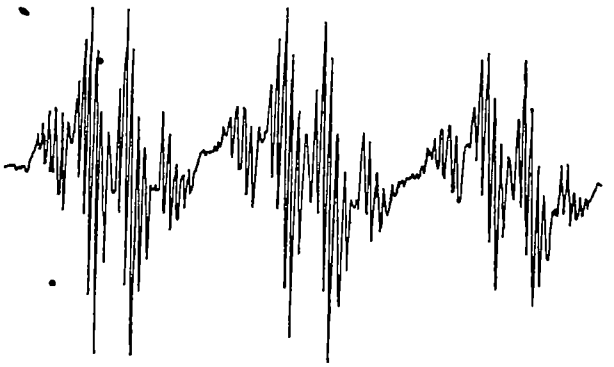

Fig. 1. Electron spin resonance of fully protonated compound

solution in tetrahydrofuran (about 0·003 M) was thoroughly deoxygenated and examined in a conventional 100 kc/s field-modulated X-band electron spin resonance spectrometer.

A well-resolved spectrum was obtained (Fig. 1) consisting of three similar groups of lines with a hyperfine coupling constant of 12·0 gauss, each group being split into four sub-groups with an intensity ratio of 1 : 3 : 3 : 1 and coupling constant of 2·36 gauss. Each of the 12 sub-groups is then further split into about 6 lines of variable width and non-binomial intensity ratios.

These data may be explained by assuming an equal (or near equal) spin density on the 2 *ortho*- and the 1 *para*-position protons.

The further splitting cannot be explained solely by coupling to the 2 *meta*-protons which would, of course, give only a 1 : 2 : 1 triplet, nor to any inequivalence of *ortho*- and *para*-proton coupling which would give a smaller number of lines in the wings compared with the more intense groups. Some degree of coupling evidently occurs with either the alkyl protons or the other aromatic group.

To resolve this ambiguity the compound was made with the alkyl protons replaced by deuterons, both the aromatic groups remaining protonated. The electron spin resonance spectrum (Fig. 2) of this partially deuterated radical is seen to resemble that of the fully protonated species in its gross hyperfine structure (a_N and $a_0 = a_p$ are the same), but to differ in its finer detail where the expected meta-1 : 2 : 1 triplets are the only features to be seen. This shows that some coupling to the alkyl chain does take place. The larger number of much more finely spaced 'deutero' lines have not as yet been resolved. The coupling constant for the *meta* aromatic protons can be determined from the deuterated spectrum and is 0·89 gauss.

Using these values it is possible to reconstruct the spectrum for the protonated radical by assuming a small coupling (a = 0·44 gauss) to one methyl group. This splits each line into four components with a 1 : 3 : 3 : 1 intensity distribution.

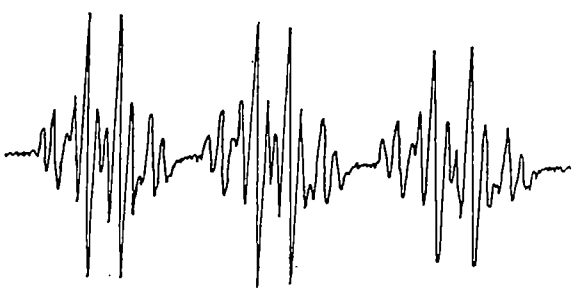

Fig. 2. Electron spin resonance of partially deuterated compound

By comparison with phenyl-*tert*-butyl nitric oxide[4], where the only proton hyperfine splitting arises from the phenyl group, it seems unlikely that coupling takes place with any of the eight nearest alkyl protons.

It appears, therefore, that the coupling is with the ε methyl group, which, sterically, may approach close to the aromatic system containing the unpaired electron. This is a case of hyperconjugation between remote parts of a molecule.

Hydration of Calcium Sulphate Hemihydrate

The results of experiments carried out in this laboratory seem to indicate that the hydration of calcium sulphate hemihydrate is initiated by the heterogeneous nucleation of crystals of gypsum, and that thereafter fresh nucleation is not important, at least so far as the kinetics are concerned[1].

Hydration in pastes is strongly self-accelerating, with a marked induction period during which reaction is slight. This is followed by a rapidly accelerating reaction, and then a period of decay during which the rate of hydration falls away to zero. The acceleration of the rate has been accounted for as follows[1,2]. The rates of growth and dissolution of the two phases of calcium sulphate in the system may be expected to be proportional to their surface areas. It has been observed that the growing crystals of gypsum in mixtures of calcium sulphate hemihydrate and water are usually in the form of plates or needles, so their surface area will be approximately proportional to the mass of gypsum. Consequently:

$$d\alpha/dt = k\alpha$$

where α is the fraction of calcium sulphate hemihydrate transformed to gypsum, t is the time elapsed after the mixing of the reagents, and k is a constant that takes into account the rate of transfer of calcium sulphate from the dissolving grains of hemihydrate to the growing centres.

$$\therefore\ \alpha = Pe^{kt} \text{ for } \alpha < \alpha_1$$

where P is the effective fraction of gypsum present at the beginning of the reaction, and α_1 is the fraction transformed at the stage when depletion of reactants and mutual interference of the growing centres causes serious deviations from the conditions that lead to an exponential rate of growth. Experimental determinations show that α_1 can be as high as 0·55 (ref. 2).

A complete theory which takes into account the processes leading to the decay of the rate can be derived when it is considered that the rate of growth of gypsum depends on the rate of dissolution of calcium sulphate hemihydrate and that the grains of hemihydrate, unlike the crystals of gypsum, are usually more or less compact geometrically. Consequently the surface area of calcium sulphate hemihydrate will be approximately proportional to the two-thirds power of the mass. Therefore, the rate of hydration may be considered in terms of:

$$d\alpha/dt = k\alpha(1-\alpha)^{\frac{2}{3}}$$

which leads to:

$$F(\alpha) \equiv \tfrac{1}{2}\log\frac{\{1-(1-\alpha)^{\frac{1}{3}}\}^2}{1+(1-\alpha)^{\frac{1}{3}}+(1-\alpha)^{\frac{2}{3}}} - \sqrt{3}\tan^{-1}\left\{\frac{2(1-\alpha)^{\frac{1}{3}}+1}{\sqrt{3}}\right\} = kt + P \text{ for } \alpha_0 < \alpha < 1 \quad (1)$$

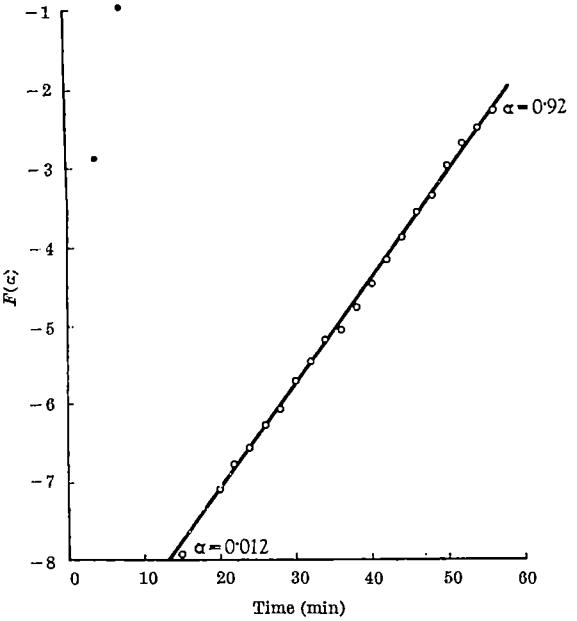

Fig. 1. $F(\alpha)$ plotted against time for 100 g calcium sulphate hemihydrate and 60 ml. water reacting at 20·5° C

Here, P is given by $F(\alpha_0)$, where α_0 is the effective fraction of gypsum at the initiation of hydration. In all these equations k characterizes the self-acceleration of hydration.

Fig. 1 shows $F(\alpha)$ plotted against time for 100 g of finely divided calcium sulphate and 60 ml. water maintained at 20·5° C. The extent of reaction was followed by chemical analysis[2]. It is seen that the kinetics conform very well with equation 1 for experimental results covering more than 90 per cent of the course of hydration.

Stability of Indanetrione Hydrate Solutions

The maximum yield of the coloured complex formed by the reaction of indanetrione hydrate[1] and a compound containing an amino-group[2] may be obtained when a reducing substance is present in the reaction mixture. Stannous chloride[3], hydrindantin[4] or potassium cyanide[5] may be used as a suitable reducing substance in the reaction mixture, provided the reaction occurs at a controlled pH[3,6].

The presence of dissolved oxygen in the reaction mixture has been reported to produce an oxidation side-reaction[3]. Indanetrione hydrate containing stannous chloride is an efficient reagent mixture but is unstable and deteriorates on storage. A precipitate occurs and the production of this precipitate is hastened when the solution is in contact with atmospheric oxygen. In this laboratory the indanetrione hydrate for the quantitative determination of nitrogen[6] (as ammonia) or α-amino-acids[7] has been prepared in small quantities immediately before use; and consistent colour factors for the α-amino-acids and amino-sugars have been obtained.

Large quantities of the reagent are required for the continuous monitoring of eluates from the automatic amino-acid analysers now in common use. The reservoir for the indanetrione hydrate reagent in the Beckman Spinco amino-acid analyser (model 120) used in this laboratory is protected from atmospheric oxygen by aspirators which may be filled with oil or water. That arrangement has been found not to exclude atmospheric oxygen and a simple procedure has been adopted to overcome the absorption of atmospheric oxygen by the water in the aspirators and also by the indanetrione hydrate solution.

A modified Fieser[8] solution has been added to the water in the aspirators: and the latter are protected from the atmospheric oxygen by connexion to a guard bubbler tube containing the concentrated Fieser solution. Air which replaces the aqueous solution in the aspirator is made to bubble through the strong Fieser solution, while the pump with a two-way valve operates to force the indanetrione hydrate solution into the reaction coil. The concentrated modified Fieser solution contained 1 g sodium anthraquinone β sulphonate, 10 g sodium hydroxide and 10 g sodium hydrosulphite per 100 ml. of the solution. The 4 l. of diluted Fieser solution in the aspirators contained 200 ml. of the concentrated modified Fieser reagent and was red in colour when prepared. The colour of the solution changed slowly to brown as oxygen was absorbed; but the addition of 10 g of sodium hydrosulphate restored the red colour, and served to regenerate the 4 l. of diluted Fieser solution. This procedure may be repeated several times before it is necessary to discard the diluted Fieser solution in the aspirators.

The use of oil in the aspirator bottles will not protect the indanetrione hydrate from the atmospheric oxygen. Fieser solution offers considerable protection for the indanetrione hydrate if the latter is stored for any period.

Some Double-layer Capacity Measurements on Platinum Electrodes

From a series of investigations of the rest potential on bright platinum electrodes[1] in oxygen-saturated acid solutions, it was suggested that the reversible oxygen potential of 1·229 V (ref. 2) is not ordinarily observed because platinum is not inert to such an electrolyte, and the system never comes to equilibrium. The Pt-O-acid system, then, is a polyelectrode[3], and the rest potential is a mixed potential[4]. It was further suggested that, if an electronically conducting surface which is inert to oxygen-saturated acid solution could be obtained, the reversible potential should be observed because, then, the system would be a simple electrode.

It was found[5] that a platinum surface could be passivated in concentrated nitric acid and that the reversible potential was observed for extended periods of time (more than 24 h). In this work, it was proposed that the nitric acid produced a complete layer of adsorbed oxygen which was an electronic conductor and did not build up with time. In order to throw light on the nature of this passivating film, the following double-layer capacity measurements were made.

A constant current single pulse technique[6] was used in which the differential capacity is determined from the relationship, $C = i/(\mathrm{d}E/\mathrm{d}t)$, where i is the current density and $\mathrm{d}E/\mathrm{d}t$ is the slope of the photographed trace obtained on the oscilloscope. Apparent current density values were used in the calculation of i. The measurements were

carried out in 'Teflon' cells[1] in 2 N sodium sulphate solution stirred with nitrogen to minimize contributions to the capacity from the pseudocapacity[7] of hydrogen or oxygen electrode processes. The preparation of the cell, solutions and electrodes was the same as that described elsewhere[1,5]. All experiments were carried out at a temperature of 25° ± 1° C and the potentials were recorded with respect to a Pt/H_2 electrode in the same solution.

In general, the procedure involved preparing the electrode under a given set of conditions, allowing the potential to come to a given potential under open-circuit conditions, stirring with purified nitrogen for 10 min, and finally pulsing the system from the resting potential. The capacity was determined from the trace obtained on the oscilloscope. It was found by monitoring the exit gas-flow from the cell with a Beckman oxygen analyser that the partial pressure of oxygen over an oxygen-saturated acid solution was reduced to a negligible quantity after bubbling nitrogen through the system for 10 min. The results are presented in Table 1 in which the pretreatment of the electrode, the potential at which the capacity was determined, and the capacity values are given. In all cases, the platinum electrodes remained smooth and mirror-bright.

Table 1. Double-layer Capacity Data on Platinum Electrodes

Experiment	Electrode pretreatment	Potential *vs.* Pt/H_2 (mV)	Double-layer capacity ($\mu F/cm^2$)
a	Clean Pt electrode in N_2 stirred 2N Na_2SO_4 solution	512	18·2
b	Bubbled O_2 over Pt electrode until potential was steady; bubbled N_2 for 10 min	995	29·9
c	Anodized Pt in separate cell; plunged Pt into O_2 saturated 2N Na_2SO_4 solution; bubbled N_2 for 10 min	942	40·8
d	Reduced anodized Pt with H_2 stirring; bubbled O_2 until potential was steady; bubbled N_2 for 10 min.	962	25·6
e	Passivated Pt in HNO_3; placed Pt in O_2 saturated 2N Na_2SO_4 solution; bubbled N_2 for 10 min	1,220	52·4
f	Bubbled H_2 over passivated Pt until H_2 potential was reached; bubbled O_2 until potential was steady; bubbled N_2 for 10 min	1,075	43·0

In experiment (*a*), the solution was stirred with hydrogen until the platinum electrode had reached the hydrogen potential (0 mV versus Pt/H_2), followed by oxygen stirring until the potential had reached 300 mV. Then, oxygen stirring was replaced with nitrogen stirring. After the potential had risen above 500 mV, the differential capacity was determined. This value of the capacity, 18 $\mu F/cm^2$, is considered to be the double-layer capacity of a platinum surface free of adsorbed hydrogen or oxygen, since the potential of 512 mV is above that point (400 mV) where hydrogen is no longer adsorbed[8,9] but below the point (800 mV) where oxygen is first adsorbed[8,10]. This capacity value is in agreement with that found by Wrotenbery *et al.*[11] in 2 N sulphuric acid, Banta and Hackerman[12] in 6 N sulphuric acid, and Laitinen and Enke[13] in 1 N perchloric acid in this potential range.

A platinum electrode free of adsorbed oxygen was stirred with oxygen until a steady rest potential was reached in experiment (*b*). After the oxygen stirring was replaced with nitrogen stirring for 10 min, the capacity was determined. Here the capacity value increased to 30 $\mu F/cm^2$.

Experiment (*c*) describes the case in which the capacity was determined on an anodized platinum electrode in a solution free of peroxide. This was accomplished by using two cells as described before[1,5]. After the electrode was prepared in one cell and the solution in the second, the electrode was removed from the first and plunged into the peroxide-free, oxygen-saturated solution in the second cell. As before, the capacity was determined after the system had been stirred with nitrogen for 10 min. A further increase in the capacity to 41 $\mu F/cm^2$ was found. When the anodized electrode was reduced with hydrogen stirring in experiment (*d*) and the conditions of experiment (*b*) repeated, the capacity was lowered again.

It appears that the differential capacity increases as the amount of oxygen adsorbed on the platinum surface increases. Although anodization does not build the adsorbed oxygen layer beyond a monolayer thick[8], it does convert some Pt-O sites to PtO_2 sites[14]. An explanation for the increase in capacity with an increase in the amount of adsorbed oxygen may include the possibility that Pt-O sites with a dielectric constant near that of a metal (the Pt-O layer[1] is an electronic conductor) replace $Pt\text{-}H_2O$ sites with a much lower dielectric constant, or that the effective thickness of the double layer is reduced by the presence of the Pt-O layer. These observations are opposite to those observed on gold[15] where the capacity decreases as oxygen adsorption increases. The oxygen layers on gold are not considered to be good electronic conductors[16], and an explanation which is the reverse of that for platinum may be considered.

A platinum electrode was passivated in concentrated nitric acid as described before[5] and placed in oxygen-saturated, peroxide-free 2 N sodium sulphate solution. After the system was stirred with nitrogen for 10 min, the capacity was determined in experiment (*e*). According to the previous experiments, the large capacity value of 52 $\mu F/cm^2$ would indicate a high coverage of the surface with oxygen, as suggested before[5]. The appearance of the reversible oxygen potential is in agreement with this contention.

When this electrode system was stirred with hydrogen until the hydrogen potential was reached, in experiment (*f*), neither the potential nor the capacity came to the same value as found in experiment (*b*) when the conditions of experiment (*b*) were used. It was found that both were higher. Repeated treatment with hydrogen stirring, and even with cathodic polarization, does not return to the nitric acid-treated platinum surface the properties of the untreated platinum surface. However, since the reversible potential is not observed, the oxygen layer in experiment (*f*) is probably no longer a complete layer. Apparently, the nitric acid treatment[5] produces a definite change in the nature of the platinum surface. By heating the platinum electrode in a hydrogen flame to white heat, it will then exhibit the properties of the untreated platinum surface.

A possible explanation may reside in the formation of an alloy of platinum and oxygen atoms by the action of the nitric acid. Kalish and Burshtein[17] have shown that massive platinum can dissolve oxygen. Such an alloy would most likely have the properties of a metal and would not easily be reduced by cathodic polarization or by reduction with hydrogen. However, heating the alloy to a white heat could drive out the oxygen. Supporting evidence is obtained from oxygen over-voltage measurements made on these electrodes (results to be published elsewhere). Because the formation of such an alloy would most likely require atomic and molecular rearrangements, it could explain the necessity for the platinum to be in contact with nitric acid for at least 72 h to form the passivating film[5].

The values of capacity found on the nitric acid-treated electrodes are near those found on anodized, untreated electrodes. This favours the idea that the passivating layer on the treated electrodes is not much thicker than a monolayer. Wrotenbery *et al.* found similar high values for the capacity of nitric acid-treated platinum electrodes in this potential region.

These results support the earlier contention[1,5] that the reversible oxygen potential may be observed on a platinum electrode only if it is covered by a complete, electronically conducting layer of adsorbed oxygen, and that, in agreement with the findings of Giner[18], the potential of a Pt/O_2 electrode becomes more noble with increasing amounts of adsorbed oxygen. The observed fact that the capacity increases with increasing amounts of adsorbed oxygen is

compatible with the concept of an electronically conducting layer of adsorbed oxygen on the platinum surface.

BIOCHEMISTRY

Caffeine Metabolism

SOME plants contain organic compounds of potent physiological action on the animal organism; but as far as is known no biological function in the plants themselves. Are they waste end-products of metabolism? Are they the result of detoxification mechanisms? Are they produced to discourage attack by insects and animals? Or are they mere 'accidents' or by-products of faulty metabolism—or perhaps even the results of evolutionary biochemical experiments not yet discarded?

The use, in biological investigations, of carbon-14 produced in nuclear bomb testing has been discussed in earlier communications[1–3]. We have used this effect to examine the caffeine metabolism in the commercial tea plant (*Camellia thea*). Commercial tea is particularly suitable for such an investigation, since it is derived from buds, less than two weeks old, of a tree many years old.

A sample of commercial tea picked in Ceylon in September 1960 was separated into caffeine and water-extracted leaves. Both the samples were converted to carbon dioxide and counted in the New Zealand Institute of Nuclear Science low-level carbon-14 counter. The $^{12}C/^{13}C$ ratio of each sample was measured in a mass spectrometer so that the results could be corrected for any isotope effect in the metabolism of the tree or any possible fractionation in the laboratory procedures. The results are given in Table 1.

Table 1. PARTS PER THOUSAND $\Delta^{14}C$ VALUES FOR CAFFEINE AND EXTRACTED BUDS OF *Camellia thea*

	Caffeine	Extracted buds
Count rate	100·08 $\sigma = 0{\cdot}35$	104·05 $\sigma = 0{\cdot}36$
$\delta^{13}C$ with respect to P.D.B. standard (parts per thousand)	−26·6	−25·4
$\Delta^{14}C$ parts per thousand*	194·6 $\sigma = 4{\cdot}7$	239·0 $\sigma = 4{\cdot}7$

$\Delta^{14}C$ of atmosphere before nuclear bomb tests = −20 parts per thousand.
σ = standard deviation of counting.
* $\Delta^{14}C$ expressed as parts per thousand enrichment above 0·95 of National Bureau of Standards oxalic acid standard and normalized for isotopic fractionation to 0·975 of P.D.B. Chicago belemnite standard.

The caffeine activity is significantly lower than that of the leaves, showing that it was not synthesized in the leaves but that it, or its precursors, were transported into the young leaves.

Although the caffeine is lower in activity than the buds, it is much higher than the atmosphere before nuclear bomb testing ($\Delta^{14}C$ = −20 per cent). No results are available for the change in carbon-14 specific activity of the atmosphere as a function of time at the latitude of Ceylon, but it might be expected to lie between that of the southern[1] and northern[5] hemispheres, the rates of increase of which had become parallel about 1958. In 1960 the specific activity of the southern hemisphere atmosphere was rising at about 6 parts per thousand per month and reached $\Delta^{14}C$ = 195 parts per thousand early in 1960 (ref. 4).

It is concluded that the caffeine corresponds to the atmosphere approximately half a year before the growth of the buds. Since the *Camellia thea* plant is some years old (7–90 years) before commercial production, it follows that caffeine is not a metabolic end-product and that it has a metabolic half-life not longer than a few months. This suggests that caffeine is involved in active metabolism.

We thank the Institute of Nuclear Science for counting the samples, and the New Zealand University Grants Committee for financial support.

Separation of Cerebroproteins of Human Brain

THE correlation of protein chemistry with complex functions of the brain has been hampered by the lack of basic information on the brain proteins. Extraction of brain proteins by techniques available so far has yielded usually less than 20 per cent of the total protein content of brain, and only up to 14 components have been demonstrable by electrophoresis[1]. Recent work in this laboratory has been directed to the definition of more quantitative methods for the extraction of brain proteins and for more adequate separation, physicochemical characterization, and histological localization by immunochemical methods[2]. We have observed that through a combination of mild buffered extraction, column chromatography on DEAE-cellulose and analysis of the carbohydrate content of each effluent tube, the presence of not less than 50 major chromatographic fractions can be distinguished (Fig. 1). Acrylamide gel-electrophoresis of each of these major fractions shows each to be heterogeneous. Accounting for overlap between chromatographic fractions, a minimum of 100 cerebroproteins from human grey matter have thus been observed. The total yield of protein in these experiments is 6·1 g/100 g wet wt. grey matter—a figure in range for previous figures for total unfractionated brain protein[3]. The previously known partially characterized protein fractions of brain[1], together with the contribution by serum proteins from blood remaining in small vessels of grey matter, are not likely to account for more than a small percentage of this total yield. Thus, the bulk of the proteins here demonstrated apparently have not been separated or examined previously.

In preliminary experiments 70 g of human grey matter, carefully dissected from autopsy specimens which had been stored at −20° C until extraction, are homogenized either in a Potter–Elvehjem homogenizer (5° C) or in a pre-cooled Waring Blender for 3 min in the cold room, with 100 c.c. of 0·005 M phosphate buffer, *p*H 7, then centrifuged at 80,000 *g* for 30 min in a Beckman model *L*-2 ultracentrifuge. The insoluble residue is rehomogenized with a further 100 c.c. of phosphate buffer and centrifuged, and the second soluble extract combined with the first. The soluble proteins thus obtained (extract *A*) account for 42 per cent of the total protein recovered.

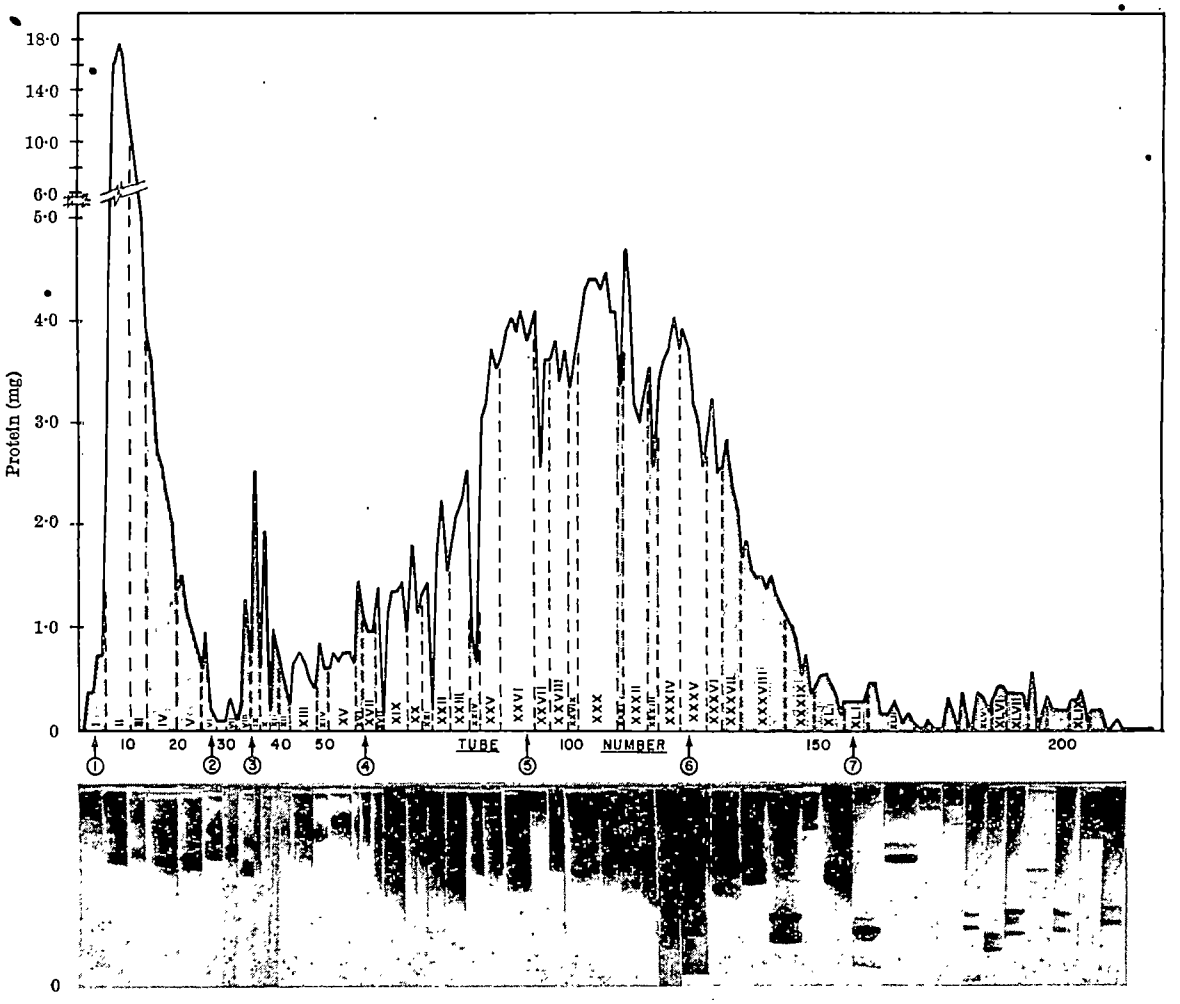

Fig. 1. Chromatography and electrophoresis of cerebroproteins of human brain. Cerebroprotein fractions are designated I–L. Shaded area represent cerebroprotein fractions with hexose content of 2·5 per cent or greater. Below each fraction is a photograph of the respective electrophoretic pattern. Numbered arrows on abscissa indicate points at which new solvents were introduced into automatic mixing chamber: (1) 75 c.c. of 0·005 M sodium phosphate buffer, *p*H 7; (2) mixture of 12·5 c.c. 0·005 M sodium phosphate buffer, *p*H 7, and 12·5 c.c. 0·05 M sodium phosphate buffer, *p*H 4·7; (3) 75 c.c. 0·05 M sodium phosphate buffer, *p*H 4·7; (4) mixture of 50 c.c. 0·05 M sodium phosphate buffer, *p*H 4·7, and 50 c.c. of 0·3 M sodium phosphate buffer, *p*H 4·3; (5) 100 c.c. 0·3 M sodium phosphate buffer, *p*H 4·3; (6) 100 c.c. 1·0 M sodium phosphate buffer, *p*H 4·1; (7) 100 c.c. 1·0 M sodium phosphate buffer, *p*H 1·0

Extraction of the residue with 0·5 M sodium chloride in 0·005 phosphate buffer, *p*H 7, yields another 6·9 per cent of the total protein recovered (extract *B*). The residue remaining after this extraction is then extracted with 0·3 per cent 'Triton *X*–100'[4] in 0·005 M phosphate buffer, *p*H 7, yielding only a further 15·8 per cent of the total recovered (extract *C*). The remaining residue has been separated into four distinct residues (residues 1–4) accounting for the remaining 35·9 per cent of the total recovered.

Extract *A* was dialysed for 4 h at 4° C against 4 l./0·005 M phosphate buffer with constant magnetic stirring of the dialysate, then concentrated approximately ten-fold against 'Carbowax' (20 M polyethylene glycol) for approximately 4 h in the cold to a final volume of dialysand between 15 and 20 c.c. This concentrate was then dialysed once more against 4 litres of phosphate buffer at 4° C with stirring. On completion, the volume of the dialysand was noted, an aliquot was taken for total protein analysis, and 15 c.c. was placed for fractionation in the cold room (4° C) on a DEAE-cellulose column 2·5 × 11·0 cm, which had been equilibrated with 0·005 M sodium phosphate buffer[5]. By the use of an automatic mixing chamber containing a constant 150 c.c. of solution, the solvent changes were made according to the schedule given in the legend for Fig. 1. Three c.c. aliquots of effluent were collected by means of an automatic fraction collector. Each tube was quantitatively analysed for protein[6], hexose[7], hexosamine[8], and neuraminic acid[9]. Where inadequate quantities were present in a single tube, 2–5 tubes were combined, lyophilized, made up to suitable volume and analysed for the carbohydrate constituents. Amino-acid analysis was performed by means of an automatic amino-acid analyser. Acrylamide disk gel-electrophoresis was performed at *p*H 9·4 (ref. 10).

Fig. 1 shows the chromatographic pattern obtained in terms of tube-to-tube protein content. The distribution suggests several relatively discrete peaks, but the presence of frequent sub-peaks makes it difficult to assess by this method alone how many protein fractions are actually represented. The tube-to-tube analysis for hexose, hexosamine and neuraminic acid of these protein fractions has here been used as one index of discreteness or non-discreteness of what appears to be a homogeneous peak on column chromatography, and sections or 'cuts' of the plotted protein values are made where gross changes in tube-to-tube carbohydrate content appear. On the basis of this combination of column chromatography and quantitative carbohydrate analysis, at least 50 discrete cerebroprotein fractions may be discerned, which are here denoted by Roman numerals I–L.

Recovery of protein from the column is 92–96 per cent. The peaks and the fractions are highly reproducible (within 2 tubes) from brain to brain, but show variation in relative amounts in different brains. The cerebroprotein

fractions in different brains also appear so far to be consistent in terms of high and low carbohydrate content respectively, as shown by the shaded and non-shaded areas respectively of Fig. 1, but the absolute amount of carbohydrate in each fraction varies. These variations may be due to age, pathological changes, post-mortem change, functional states at death, or individual variability, and these, as well as other possibilities, must be explored in future investigations.

Examination of each of the 50 cerebroprotein fractions by means of disk gel-electrophoresis reveals that each contains between two and eleven electrophoretically clearly separated protein zones or sub-fractions (Fig. 1). Allowing for overlap, a minimum of 100 cerebroproteins can be distinguished. Whether some of these differ only in molecular size, only in a few amino-acid residues, only in a few attached carbohydrate groups, or in some other minor structural way, cannot be ascertained at this point, but they differ sufficiently to be separable by means of electrophoresis.

It may be noted that the carbohydrate content frequently, although not invariably, tends to increase as one passes from the first to the last tube of a given chromatographic peak. For example, proceeding from cerebroprotein fraction II to VI, the hexose increases from 0·2 per cent to 6·6 per cent. Two areas in these first chromatographic fractions were analysed for constituent amino-acids in hydrolysed samples. The residue of amino-acids per thousand for almost all the amino-acids was similar or identical with two marked exceptions: serine and glutamic acid. Thus, comparison of the two cerebroprotein fractions showed one to have twice as many serine residues per thousand (123·3 compared with 62·9), and 50 per cent more glutamic acid residues per thousand (75·1 compared with 50·7) as the other. Since there is considerable evidence in other glycoproteins that these two amino-acids are involved in the linkage of carbohydrates to proteins, this variability in only carbohydrate content and a few amino-acid residues is of considerable interest and will be examined further.

In addition to specific isolation and characterization investigations of these human cerebroproteins, specific antisera are being prepared for immunological tests of homogeneity, and for the demonstration of the histological localization in cell types (neurones or glia), and in different architectonic layers of the cerebral cortex. The use of histochemical methods for the assessment of enzyme activities in each of these protein fractions has also begun, has been shown by us to be applicable to the esterases, and will be carried out with other enzymes as well.

These methods permit a more thorough examination of the biosynthesis of brain proteins[11], and offer an opportunity not previously available for the investigation of a broad range of neurologic and psychiatric disorders with regard to the possible implication of some of these proteins in pathological processes.

All the data in Fig. 1 pertain to extract *A* only. These discernible and separable proteins represent only 42 per cent of the total prepared by us from grey matter alone. It is clear that years of work lie ahead for many laboratories in terms of the further physical and chemical definition of species of proteins in human and other mammalian brain. The occurrence of such a multitude of individual proteins may not seem unreasonable when the complex functional requirements of the brain, such as those pertaining to the specificity of interneuronal transmission and the need for specificity in such functions as memory[12], are taken into account. The specificity of coding in the amino-acid chains of proteins has elsewhere been shown to be fundamental to specificity of function, as in the case of hormones, and in antigen–antibody reactions; and, as pointed out before[2], the type and sequence of carbohydrate units of the glycoproteins and amino-glycolipids of brain offer further opportunities for molecular specificity.

Sialic Acid-deficient α_1-Acid Glycoprotein produced in Certain Pathological States

THE seromucoid fraction, one of the 'acute phase reactants', has been shown by many investigators to be increased significantly in the blood in a large number of unrelated disease states. This protein fraction[1] is known to contain as major component α_1-acid glycoprotein[2] or orosomucoid[3] and several minor components including haptoglobin, 3*S* α_1-glycoprotein and Zn- and Ba-α_2-glycoproteins[4,5]. The question has now been investigated whether α_1-acid glycoprotein derived from pathological plasma is identical to or different from that prepared from normal blood.

α_1-Acid glycoprotein was isolated by a two-step procedure from certain blood specimens. First, the sera were fractionated according to a modification of the Cohn method 10 (ref. 6). Second, the resulting fractions VI[2] were chromatographed on 'Amberlite *IRC*-50'[7] yielding α_1-acid glycoprotein preparations which appeared homogeneous on paper and starch-gel electrophoresis at *p*H 8·6. Sialic acid was determined by the techniques of Warren[8]. The seromucoid fraction, prepared and analysed according to Winzler[9], served as control to demonstrate the changes of the glycoproteins level of the plasma.

Two representative series of experiments are reported here.

An apparently healthy male, 66 years old, underwent an arterial graft operation. No post-operative complications were observed. As expected, the concentration of the seromucoid fraction rose rapidly and, thereafter, decreased gradually (Table 1). The amount of fraction VI the composition of which is similar to, but not identical with, that of the seromucoid fraction, and α_1-acid glycoprotein isolated from the three blood specimens followed a similar course. The sialic acid content of these three protein preparations, however, was constant and equal to that of normal α_1-acid glycoprotein.

Table 1. SIALIC ACID CONTENT OF α_1-ACID GLYCOPROTEIN DERIVED FROM SERUM OF A PATIENT WHO UNDERWENT AN ARTERIAL GRAFT OPERATION

Blood taken	α_1-Acid glycoprotein		Fraction VI (mg %)	Seromucoid (as Biuret) (mg %)
	Sialic acid content (%)	Blood level (mg %)		
1 day pre-op.	11	70	130	84
2 days post-op.	11	120	210	127
12 days post-op.	11	80	194	114
Normal values	11	45	110	61 ± 8

Sera from certain patients suffering from various chronic diseases revealed the anticipated increased seromucoid levels (Table 2). Again, the blood concentration of fraction VI and α_1-acid glycoprotein was shown to be elevated about equally. It was of interest to note, however, that the sialic acid content of many of these α_1-acid glycoprotein preparations was significantly lower than that of the normal glycoprotein. In certain cases values of approximately 50 per cent of the normal were observed.

Table 2. Sialic Acid Content of α_1-Acid Glycoprotein derived from Sera of Patients suffering from Certain Chronic Diseases

Diagnosis	α_1-Acid glycoprotein Sialic acid content (%)	α_1-Acid glycoprotein Blood level (mg %)	Fraction VI (mg %)	Seromucoid (as Biuret) (mg %)
Hodgkins' disease	8·3	119	182	121
Psochiaric arthritis	8·3	205	260	147
Diabetes	6·3	108	203	98

From these results it might be concluded that normal individuals subjected to an intense but temporary stress produce the expected augmented quantity of normal α_1-acid glycoprotein. In contrast, patients with certain chronic diseases who have probably produced α_1-acid glycoprotein in abnormally large amounts over a long period of time form an α_1-acid glycoprotein that lacks sialic acid to varying degrees.

Lysozyme Content of Human Milk

Lysozyme has been detected in the milk of donkey, mare, bitch, sow and cow[1,2]. In order to investigate the possible biological significance of lysozyme an investigation is planned here to compare physical, chemical and physiological characteristics of the lysozymes isolated from bovine and human milk. Although several workers[1–4] have reported the presence of lysozyme in human milk and colostrum, not much work has been done to obtain information on the quantitative amounts of the enzyme in this milk. In the work recorded here lysozyme contents of a large number of bovine and human milk samples were determined. In an earlier publication[2] the lysozyme content of bovine milk was reported to vary between 0·0 and 260·0 μg with an average of 13 μg of the enzyme activity per 100 ml. of milk, using egg-white lysozyme (Difco) as the standard. This report deals with the lysozyme content of human milk and colostrum, and the effect of storage and heat on the enzyme.

The samples of milk and colostrum were collected from the maternity wards of the University Medical College and the local hospitals and held frozen until they could be assayed. The milk was assayed for lysozyme by the method of Smolelis and Hartsell[5], as modified and adapted to milk[2]. The modified procedure involved the dilution of the milk 1,000–3,000-fold with water, mixing it with an equal volume of a substrate consisting of a suspension of dead cells of *Micrococcus lysodeikticus* (Difco) and observing the extent of lysis spectrophotometrically. The details of the method are described in our earlier publication[2].

The lysozyme contents of 105 samples of human milk and 12 samples of colostrum, summarized in Table 1, indicated that human milk and human colostrum contain lysozyme in similar concentrations. This was also observed in the case of bovine milk and bovine colostrum in our previous investigation. However, the results did not bear out the possibility that colostrum might possess higher lysozyme titres than the post-colostrum milk, since it is known to contain natural immunological factors.

The lysozyme content in human milk ranged from 3 to 300 mg/100 ml. with an average of 39 mg/100 ml., or about 3,000 times higher than that of bovine milk. The results presented in Table 1 represent 117 samples and 105 subjects. Jollès and Jollès[3] reported the lysozyme content of human milk as 4 mg/100 ml. The numbers of samples and subjects in their investigation were not reported, however.

During the course of this work it was observed that the lysozyme activity of human milk was best preserved when the milk was held frozen. However, frequent thawing and refreezing of the milk inactivated the lysozyme activity considerably. It was further observed that human milk when not previously frozen could be held at room temperature or even at 30° C without any significant loss of activity up to 3 or 4 days or until the milk spoiled. In this regard it differed widely from bovine milk, which lost its lytic activity completely within 8 h at 30° or 37° C when the milk spoiled. These results are in accordance with the observations of Seleste[4], who has pointed out the remarkable keeping quality of the enzyme in human milk and of human milk itself. It is conceivable that the rapidly growing microflora contributing to the spoilage of cow's milk inactivate its lytic factor, and that the initial low bacterial content and higher *p*H of human milk do not permit a rapid bacterial multiplication and thereby provide the inherent high keeping quality of lysozyme in human milk and of human milk itself.

Table 1. Lysozyme Contents of Human Milk and Colostrum

Sample	No. of samples	Lysozyme (mg/100 ml. milk) Minimum	Maximum	Average
Human milk	105	3	300	39
Human colostrum	12	9	102	46

Table 2. Effect of Heat-treatments on Lysozyme Activity of Human Milk at its Natural *p*H

Sample No.	Lysozyme concentration (mg/100 ml.) Before heating	62° C for 30 min	After heating 71° C for 15 sec	71° C for 15 min	71° C for 30 min	82° C for 15 sec	82° C for 15 min	82° C for 30 min	Momentarily boiling	Autoclaving 15 lb./in.², 20 min
1	18·0	4·4	12·0	0·4	0·0	9·6	0·1	0·0	1·0	0·0
2	12·0	8·8	9·6	5·0	3·2	7·4	1·8	0·4	6·2	0·0
3	4·2	2·4	2·6	1·4	0·8	2·4	1·0	0·0	1·4	0·0
Average % destruction		47·0	30·0	74·0	88·0	43·0	87·0	99·0	68·0	100·0

In order to determine the heat stability of the lytic factor(s) in milk, three fresh human milk samples varying widely in lysozyme activity were heated at 62°, 71° or 82° for varying lengths of time, and the lytic activity of milk before and after these heat treatments was determined. The results showing the percentage destruction of the enzymatic activity by the heat treatments are presented in Table 2.

A fairly wide variation was observed in the heat stability of the lysozyme of the three samples of human milk. An average of 47 per cent of the lysozyme activity was lost when the milk was heated at 62° C (143° F) for 30 min, the conventional batch pasteurization process for milk, and 30 per cent was lost at 71° C (160° F) for 15 sec, the conventional high-temperature, short-time pasteurization procedure for milk. Heating at 82° C for 15 sec lowered the enzyme activity by 43 per cent, and momentary boiling caused 68 per cent loss of the enzymatic activity. When the milk was autoclaved at 15 lb./in.^{2} for 20 min, a complete inactivation of the lysozyme was observed. In regard to heat stability the human milk lysozyme closely resembled bovine milk lysozyme.

The human milk lysing factor was found to be more resistant to heat at acid *p*H than at higher *p*H levels, being most stable at *p*H 3 and 4. At *p*H levels 1, 2, 3, 4 and 5 complete inactivation of the enzyme resulted after boiling for 38, 92, 164, 142 and 60 min, respectively; at *p*H 6, 7 and 8 all the enzyme activity was destroyed by boiling only for 4, 1 and 0·1 min, respectively. No lysozyme activity was observed in human milk adjusted to *p*H 9, 10, 11 or 12.

The lysing factor of human milk appears to be a lysozyme since it lyses *Micrococcus lysodeikticus* cells and is fairly stable to heat, especially at acid *p*H, as is the egg-white lysozyme.

Lysozymes from both human and bovine milk have been isolated in a pure and homogeneous form using the method of Jollès and Jollès[5] with several modifications. The results of that investigation have been presented elsewhere[6].

This work was supported by a grant from the U.S. National Institutes of Health (*HD*–00858–01). We thank Drs. Morgan and Ebers for assistance in collecting human milk samples.

A Reaction of Pyridoxal with C-3 Unsubstituted Indoles

The formation of a red pigment from indole and pyridoxal interferes in the enzymatic determination of L-tryptophan[1]. On the basis of the following evidence, it is proposed that the pigment has the structure II*a* shown in Fig. 1 and is therefore analogous to the roseindoles of Fischer[2].

Since C-3 is the most reactive position in the indole ring in electrophilic substitution[3] and since pigment formation is inhibited by dimedone[1], a condensation between the aldehyde group of pyridoxal and C-3 of indole was considered as a possible reaction in the production of the red pigment.

Aldehydes condense with C-3 unsubstituted indoles to give products analogous to the triphenylmethanes. Oxidation of the initially-formed leuco base (I) gives a yellow base with a system of conjugated double bonds (II). Salts of base II are intensely coloured, due to resonance; the positive charge is distributed between both nitrogen atoms in two identical mesomeric structures. The roseindoles, from the condensation of benzaldehyde with indoles (R_1 = phenyl)[2], are a classical example of this type of compound.

II*a*, II*b*, II*c* and II*d* have been prepared as the free bases and as the hydrochlorides. The hydrochlorides were synthesized by passing dry hydrogen chloride into a dry ethereal solution of the free base, whereupon the pure hydrochloride was immediately precipitated in quantitative yield. Under absolutely dry conditions, with protection from atmospheric moisture, the dihydrochlorides were formed. This confirms the presence of two basic nitrogen atoms in the molecule. In the atmosphere the dihydrochlorides rapidly lost one molecule of hydrochloric acid to become monohydrochlorides, which were recrystallized from ethanol/ether.

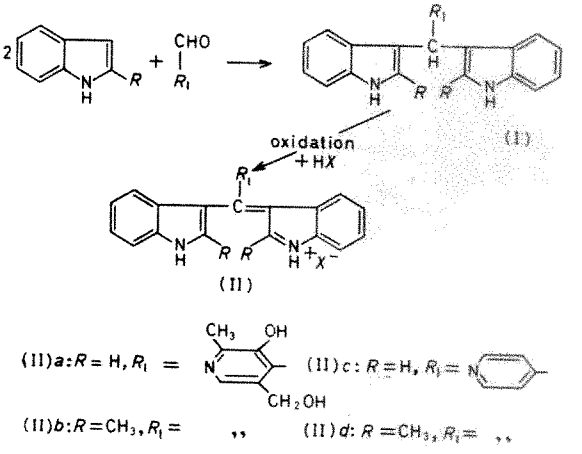

Fig. 1

Since the uroroseins (R_1 = H)[4] and the roseindoles (R_1 = phenyl)[2] form stable monohydrochlorides, the positive charge is probably shared equally between both pyrrole nitrogen atoms in the monohydrochlorides of the indolinylidene–indolyl–pyridylmethanes.

On recrystallization, the free bases stubbornly retained some solvent. When dried at 100°, the carbon values were 2–3 per cent too low. After drying at 150°, the combustion analyses gave values in agreement with those calculated.

Although compound II*a* is formed in the reaction of pyridoxal with indole in 2 N hydrochloric acid, the chief product is an unidentified yellow compound. In 25 per cent trichloroacetic acid, that is, the conditions under which II*a* was first observed, the yield of II*a* is about 70 per cent.

Satisfactory melting points of the pyridoxal compounds were not recorded. They decomposed at indefinite temperatures, depending on the rate of heating.

That all four compounds possess the same chromophore is confirmed by comparison of their visible and ultraviolet spectra. The free bases show a typical indole maximum in the region 250–292 mμ, which shows little change in acid. A shoulder in the region 330–360 mμ becomes a slight peak in acid. The absorption at 430–460 mμ, responsible for the yellow colour of the free bases, exhibits a marked red shift of about 100 mμ and an increase in intensity under acid conditions. Spectra were made by hand on a Unicam *SP*.500 spectrophotometer.

3-*Indolinylidene*-3-*indolyl*-4-(2-*methyl*-3-*hydroxy*-5-*hydroxymethylpyridyl*)*methane* (IIa): 33·4 mg of pyridoxal and 46·8 mg of indole were dissolved in 400 ml. of 2 N hydrochloric acid and allowed to stand two days at room temperature. The red solution was extracted with ether until the ether washings were negative for indole (*p*-dimethylaminocinnamaldehyde reagent[1]). The aqueous hydroxide solution was then made alkaline with conc. ammonium and the yellow pigment extracted with ether. After washing twice with water, the ether solution was dried over anhydrous sodium sulphate and gently blown to dryness in a stream of nitrogen. The remaining solid was recrystallized from ether/petrol ether (40°–60°). The yield was 20 mg (26 per cent). Free base: calc. for $C_{24}H_{19}O_2N_3$, C, 75·53; H, 4·98; N, 11·02 per cent; found, C, 75·41; H, 5·17; N, 10·98 per cent. Hydrochloride: calc. for $C_{24}H_{19}O_2N_3$.HCl, C, 68·98 ; H, 4·78 ; N, 10·06; Cl, 8·50 per cent; found, C, 68·90; H, 5·01; N, 9·93; Cl, 8·47 per cent.

3-(2-*methyl*-*indolinylidene*)-3-(2-*methyl*-*indolyl*)-4-(2-*methyl*-3-*hydroxy*-5-*hydroxymethyl pyridyl*)*methane* (IIb): 33·4 mg of pyridoxal and 52·4 mg of 2-methylindole were dissolved in 400 ml. of 2 N hydrochloric acid. The procedure was exactly as for IIa. The yield was 70 mg (81 per cent). Free base: calc. for $C_{26}H_{23}O_2N_3$, C, 76·47; H, 5·39; N, 10·29 per cent; found, C, 76·37; H, 5·70; N, 9·92 per cent. Hydrochloride: calc. for $C_{26}H_{23}O_2N_3$.HCl, C, 70·03; H, 5·38; N, 9·42; Cl. 7·96 per cent; found, C, 69·98; H, 5·40; N, 9·46; Cl, 7·96 per cent.

Table 1. Extinction Coefficients of 3-Indolinylidene-3-indolyl-4-pyridyl-methanes

	Free bases in ethanol			
	λ_{max} (mμ)	log ε	λ_{max} (mμ)	log ε
IIa	280	4·07	440	3·08
IIb	282	4·03	430	3·33
IIc	282	4·08	450	1·52
IId	280	4·03	460	3·47
	In 1 N hydrochloric acid			
IIa	282	4·10	530	3·32
IIb	260	4·06	540	3·74
IIc	282	4·10	540	2·32
IId	282	4·15	550	3·52

3-*Indolinylidene*-3-*indolyl*-4-*pyridylmethane* (IIc): 2·19 g of indole and 1·0 g pyridine-4-aldehyde were dissolved in 4 ml. of glacial acetic acid and allowed to stand two days at room temperature. After this time the mixture was deep purple. Water was added until precipitation just started and then ammonia until the mixture was just alkaline. The copious yellow precipitate was collected by filtration, washed with water and dried *in vacuo* over phosphorus pentoxide. The compound could be purified by precipitation from ether or ethyl acetate with petrol ether (40°–60°) to give an amorphous product, or by slow recrystallization (2 days) from ethanol. Both forms had the same melting-point: 155° (uncorr.). The yield was 2·7 g (90 per cent). Free base: calc. for $C_{22}H_{15}N_3$, C, 82·24; H, 4·65; N, 13·08 per cent; found, C, 82·10; H, 4·90; N, 13·00 per cent. Hydrochloride: melting point 205° (uncorr.): calc. for $C_{22}H_{15}N_3$.HCl, C, 73·56; H, 4·47; N, 11·74; Cl, 9·93 per cent; found, C, 73·20; H, 4·51; N, 11·76; Cl, 9·78 per cent.

3-(2-*Methyl*-*indolinylidene*)-3-(2-*methyl*-*indolyl*)-4-*pyridylmethane* (IId): 2·54 g of 2-methylindole and 1·0 g of pyridine-4-aldehyde were dissolved in 2 ml. of glacial acetic acid and allowed to stand 2 days at room temperature. The mixture became deep purple and there was a thick deposit of colourless crystals. The whole was diluted with two volumes of ethanol and filtered; the crystalline deposit remained undissolved. The coloured filtrate was neutralized with conc. ammonium; a yellow precipitate was formed, which was collected by filtration and recrystallized from ethanol/petrol ether (40°–60°). The yield was 0·5 g (18 per cent). Free base: melting point 160°–161° (uncorr.): calc. for $C_{24}H_{19}N_3$, C, 82·52; H, 5·44; N, 12·03 per cent; found, C, 82·20; H, 5·48; N, 11·89 per cent. Hydrochloride: melting point 215° (decomp.): calc. for $C_{24}H_{19}N_3$.HCl, C, 74·70; H, 5·18; N, 10·98; Cl, 9·20 per cent; found, C, 75·00; H, 5·25; N, 10·50; Cl, 9·13 per cent.

The combustion analysis of the colourless, crystalline substance from this preparation indicates that it is a leuco compound of type I, that is, 4-(3,3′-di-2-methylindolylmethyl)-pyridine. It was recrystallized from acetone.

Melting point 249°–250° (uncorr.). The yield was 2·4 g (74 per cent). Calc. for $C_{24}H_{21}N_3$, C, 82·05; H, 5·98, N, 11·96 per cent; found, C, 82·04; H, 6·01; N, 12·10 per cent. It was oxidized in almost quantitative yield to II*d* by ferric chloride in acetic acid, exactly as described by Fischer for the analogous phenyl compounds[2].

Glycolysis and Respiration of Transformed *BHK*21 Cells

WARBURG *et al.*[1] observed that tumour tissues almost always had a higher rate of aerobic glycolysis than normal cells. Warburg attributed this to irreversible damage to the respiratory pathways. The theory was a source of contention from the beginning. It was abandoned by most workers when it was found that glycolysis very rapidly increased (in a few days) when tissues were explanted and maintained as tissue cultures[2–4]. Since then many factors, such as *p*H and oxygen tension, have been shown to influence both glycolysis and respiration in cultured cells[5–7]; the increase of glycolysis on explantation can easily be explained by these findings. Reduced respiration and increased glycolysis in tumours *in vivo* can be explained similarly, knowing that most tumours have an inadequate blood supply. For this reason, and because wide differences in behaviour are found among different cell lines[8], the significance of Warburg's findings has been questioned. Nevertheless, there is good evidence[9,10] that there is a fundamental difference in glycolysis of normal and tumour cells.

To test the question critically, systems are needed in which closely related normal and malignant cells can be compared in identical conditions. Ideally, the lines should be grown *in vitro*, should be derived from the same cell and should have diverged from it very recently. These requirements have been met by the isolation of a stable line of baby hamster kidney cells, designated *BHK*21, which can be transformed into cells of different morphology by the *SE* polyoma virus[11,12]. Cells transformed in this way have the properties of tumour cells, whereas the 'untransformed' cells used by us in this study have very low transplantability. Both have a similar growth rate and high cloning efficiency[13]. It is possible to derive equivalent sub-clones of either normal or transformed cells from within a single clonal population and to compare them directly. The lines used in the work recorded here were clones derived simultaneously from the same cell inoculum which was exposed to polyoma virus[14]. *A* and *C* were morphologically untransformed and clones *Y* and *Z* transformed. *A*, *C* and *Y* are predominantly diploid and *Z* near tetraploid. The cells were maintained in Eagle's medium with 10 per cent calf serum and 10 per cent tryptose phosphate broth.

Respiration was measured with the Cartesian diver by techniques which have been detailed elsewhere[15]. Glycolysis was measured by estimating the glucose used and lactate produced by 2×10^6 cells in 2 ml. medium in 17 h. Since these cells produce large amounts of lactic acid and *p*H has a profound effect on glycolysis[5] the medium was heavily buffered. The incubations were performed in 25 ml. conical flasks maintained in a shaking water-bath at 37° C. Table 1 shows comparative values for respiration; if anything it is higher in the transformed strains. Table 2 shows comparative values for glycolysis; it is clear that the transformed cells have

Table 1. RESPIRATION OF TRANSFORMED AND UNTRANSFORMED CELL LINES DERIVED FROM *BHK*21 AFTER TREATMENT WITH POLYOMA VIRUS

Respiration was measured at *p*H 7·4 in a salt solution in equilibrium with 5 per cent carbon dioxide in air

Exp.	Cell strain and type	Oxygen uptake μM/h/mgDNAP
1	*A* (untransformed)	509, 439
	Y (transformed)	451, 553
2	*A* (untransformed)	467, 505, 550
	Y (transformed)	598, 659, 534

Table 2. GLYCOLYSIS OFTRANSF ORMED AND UNTRANSFORMED CELLS

Glucose utilization was measured for 17 h at *p*H 7·4 in a medium in equilibrium with 5 per cent carbon dioxide in nitrogen. (10^6 cells: 0·8 mg DNAP)

Type of cell	Strain	No. of obs.	Glucose uptake μM/h/10^6 cells (mean ± *S.D.*)
Untransformed	*A*	4	336 ± 104
		4	418 ± 57
		4	317 ± 36
	C	3	190
			347 ± 37
Transformed	*Y*	3	667
		4	574 ± 43
		4	601 ± 56
	Z	3	978
		4	660 ± 80
		4	777 ± 80

greater glycolytic capacity than the untransformed. Enzymatic investigations have been undertaken to reveal the underlying nature of this difference and will be reported elsewhere.

While these findings provide no support for Warburg's view that tumour cells have an irreversible lesion of the respiratory pathways they very strongly support his contention that there is a marked difference in the glycolysis of normal and tumour cells. Before drawing a firm general conclusion to this effect it would be desirable to carry out similar studies on other systems, including some in which a malignant transformation was produced by agents other than viruses. Defendi[16] has described a spontaneously arising variant of *BHK*21 which (unlike the untransformed cells used in this work) is highly malignant though it has the appearance of an untransformed strain. Some untransformed lines maintained by us for a very long time are also malignant[12,13]. Another untransformed line which has been maintained continuously for very many passages has been found to exhibit a high rate of glycolysis. Its transplantability is being tested, having in mind the possibility of a correlation between transplantability and high glycolytic capacity.

While we feel it would be unwise to draw a general conclusion until we have more information, we consider that the results obtained in this work warrant a reappraisal of the role of glycolysis in carcinogenesis.

Occurrence of Farnesene in the Natural Coating of Apples

Previous investigation of the cuticle oil of the 'Granny Smith' apple in this Laboratory indicated the presence of small amounts of a hydrocarbon with a conjugated diene absorption in the ultra-violet. In view of its possible connexion with the serious storage disorder 'superficial scald' it was isolated, and it has now been identified as the sesquiterpene farnesene (2,6-dimethyl-10-methylene-2,6, 11-dodecatriene)[1,2].

'Granny Smith' apples (700 kg), stored at 1° C for six months, were washed with cold ethyl ether. The recovered coating (ursolic acid, cuticle wax and oil), freed of ether, was extracted with cold light petroleum (b.pt. below 40° C), and the extract after concentration was treated with urea and methanol. The oily material not adducted by urea was chromatographed on 'Florisil'. Infra-red spectra of the material in the fractions eluted by light petroleum indicated a small saturated hydrocarbon fraction (80 mg) followed by fractions (750 mg) all showing the presence of unsaturated hydrocarbon. Gas chromatography on silicone and polyester columns of the unsaturated material showed one predominant peak and the compound responsible was recovered in a pure state from the silicone column. It has been positively identified as natural farnesene on the basis of the following evidence: (*a*) its mass spectrum showed a molecular ion of $m/e = 204$; (*b*) its infra-red spectrum was identical with that published for pure natural farnesene[3]; (*c*) hydrogenation on platinum in glacial acetic acid yielded farnesene (2,6,10-trimethyldodecane)[1], identified by its published infra-red spectrum[2] as well as by direct comparison of its infra-red and mass spectra and gas chromatographic retention times on the above columns with those of an authentic specimen prepared from pure farnesol[1].

Farnesene in the isolated fractions was observed to polymerize rapidly at room temperature in the presence of air, whereas it is stable in the whole extracted apple coating for about a year. Its labile nature and the fact that it constitutes at least 1 per cent of the 'Granny Smith' cuticle oil fraction has suggested to us that it may have a role in the development of superficial scald. Work is in progress to examine this hypothesis.

Ubiquinone-40 and Vitamin K_2 (40) in *Chromatium vinosum*

Chromatium, an obligate photosynthetic anaerobe belonging to the purple sulphur bacteria (Thiorhodaceae), has been examined by several workers for the presence of lipophilic quinones. Thus, *Chromatium*, strain *D*, contains ubiquinone-35 (UQ_7; 2·7 μM/g, dry wt.) and a vitamin K (refs. 1 and 2); both these quinones were found in the chromatophores[2]. *Chromatium* 8379 was reported as having large amounts of ubiquinone-50 (UQ_{10}) and a vitamin K_2 (ref. 3). Recently we have had the opportunity of examining *C. vinosum* for the presence of ubiquinone and vitamin K and have established the chain-length of the quinones present.

C. vinosum used was obtained from Lake Beloye (near Moscow), and shown to be photoautotrophic, requiring only carbon dioxide and hydrogen sulphide for growth[4]. It was grown on the following medium (g/l. distilled water): NH_4Cl, 1; K_2HPO_4, 0·5; $MgCl_2$, 0·2; NaCl, 5; $Na_2S\ 9H_2O$, 2; $NaHCO_3$, 5 (*p*H 7·8–7·9). The medium was dispensed in 250 ml. stoppered 'Pyrex' bottles, inoculated from a previous liquid culture, and grown anaerobically at 28° with constant illumination from tungsten lamps.

After 7 days the cells were collected by high-speed centrifugation (2,230 ml. media ≡ 204 mg dry wt. of cells) and the wet cell mass extracted twice with hot methanol (75 ml.) followed once by a hot ether–methanol mixture (3:1, v/v; 75 ml.) The methanolic extracts were separated from the cell debris by centrifugation, the supernatants decanted into a separating funnel and the ether washed free from methanol with distilled water. The ethereal layer was dried over anhydrous sodium sulphate (1 h), filtered and taken to dryness under a stream of nitrogen. This yielded 64·3 mg of a dark red oil.

The lipid extract was chromatographed on 10 g Brockmann grade III acid-washed alumina ('Woelm'); 100-ml. fractions of light petroleum (40°–60°) containing increasing amounts (0·25, 1, 3, 5, 8, 12 and 20 per cent) of ether (peroxide free) were collected. The 1 per cent ether–light petroleum fraction eluted 1·1 mg of a pale yellow oil with selective absorption bands in the ultra-violet region at λ_{max} 243, 249, 251 and 260 ($E^{1\%}_{1\,cm}$ 120, 122, 111 and 106) in *cyclo*hexane characteristic of the vitamins K. The 5 per cent ether–light petroleum fraction eluted 1·5 mg of an orange-brown oil having a single absorption band at λ_{max} 275 mμ ($E^{1\%}_{1\,cm}$ 77) in ethanol; on treatment of this fraction with $NaBH_4$ the absorption at 275 mμ declined and a new peak appeared at λ_{max} 290 mμ; these changes are attributable to the presence of ubiquinone. In agreement with work carried out on *Chromatium* 8379 (ref. 3), tocopherols were not detected in any of the fractions. The levels of ubiquinone (from the spectroscopic changes on treatment with $NaBH_4$ using λ_{max} 275 mμ ($\varepsilon_{oxid} - \varepsilon_{red}$) = 12,250) and vitamin K (using λ_{max} 249 mμ ε = 19,000) in the fractions were estimated and the concentration per unit weight of cell material calculated as 2·5 μM UQ/g dry wt. and 3–3·5 μM vitamin K/g dry wt. Since the estimation of vitamin K in the original fraction was difficult owing to irrelevant end absorption, a higher value was obtained on the crude fraction and a lower one was obtained after further purification by thin-layer chromatography (see below).

In order to characterize the quinones the fractions were purified further by quantitative thin-layer chromatography on 'Kieselgel *G*' plates impregnated with rhodamine 6 *G*. The plates were developed in a saturation chamber[5] with benzene–chloroform (1:1, v/v) as developing solvent (vitamin K $R_F = 0{\cdot}68$, UQ $R_F = 0{\cdot}3$). After development the quinones, visible as dark bands in daylight (under ultra-violet light the bands are more intense), were scraped off into ether and filtered to remove the gel and rhodamine. The recovered quinones had ultra-violet spectra qualitatively identical to those of vitamin K and ubiquinone.

The ubiquinone recovered from thin-layer chromatograms was then chromatographed against standards in two ascending reversed-phase systems which allow the separation of the various homologues[6,7]. The quinones were visualized by spraying with leucomethylene blue[7]. In both systems the ubiquinone behaved as the −40 homologue (UQ_8).

The vitamin K sample, from its behaviour on thin-layer absorption chromatograms, was assigned to the K_2 series, since in the system described above it was resolved from vitamin K_1 and run with the vitamins K_2 (45) and (40). Accordingly, the sample was chromatographed against vitamin K_2 standards in two reversed phase systems[8,9] which will resolve the various isoprenologues. In both cases the menaquinone ran with and was not separated from vitamin K_2 (40). Additional evidence as to the

identity of the quinones was obtained from microhydrogenation (Adams catalyst) investigations. In both cases the hydrogenated samples of ubiquinone and vitamin K_2 from *Chromatium* when run on paper chromatograms[6,9] ran with the corresponding authentic perhydro derivatives of ubiquinone-40 and vitamin K_2 (40).

In agreement with the experiences of other workers[1-3] with different strains of *Chromatium* we have found the *C. vinosum* has a high level of ubiquinone and vitamin K_2; our value for the former quinone (2·5 μM UQ_8/g dry wt.) is similar to those reported for *Chromatium*, strain *D* (2·7 μM UQ_7/g dry wt.)[1,2]. It is of interest that both quinones in *C. vinosum* should have the same chain-length, suggesting a common biosynthetic sequence. Of systematic importance is the observation that of the three strains of *Chromatium* so far examined each contains a different ubiquinone homologue; unfortunately it is not possible at this time to make a similar comparison for the vitamins K.

We thank Dr. F. W. Hemming, Department of Biochemistry, University of Liverpool, for providing the ubiquinone and vitamin K_2 standards. This work was supported in part by the Department of Scientific and Industrial Research.

Cellulase from Pea Epicotyls

Seedlings of *Pisum sativum* L. var. 'Alaska' were grown in darkness for 8 days and extracts of the apical 6 cm of epicotyl were examined for ability to catalyse the degradation of cellulose derivatives. After the tissue was washed in hypochlorite and weighed, 0·5 vol. of cold 0·1 M phosphate *p*H 7·0–0·01 per cent cysteine was added and a brei was prepared by blending at top speed with a 'VirTis' homogenizer. The brei was centrifuged at 37,000*g* for 20 min at 0° C and the precipitate was homogenized and extracted again. The combined supernatants were saturated with toluene and re-centrifuged just before use as crude extract. In order to remove contaminating reducing substances, 2 vol. of cold acetone were added and the precipitate was washed with 70 per cent acetone, dissolved in water, re-precipitated with ammonium sulphate at 60 per cent saturation, suspended in water and re-centrifuged. The final supernatant was used as purified extract.

Fig. 1 shows curves for the action of extract, and the supernatant from boiled extract, on the viscosity of carboxymethylcellulose solution (CMC, type 7*MSP*, Hercules Powder Co.). The substrate alone is stable for at least 10 days under the condition of the experiment but the addition of boiled extract causes a slow steady fall in viscosity, that is, a fall in the degree of polymerization of CMC. This non-enzymatic degradation has been observed before with heated extracts from cabbage tissue[1]. With active extract the viscosity is induced to fall at a rate

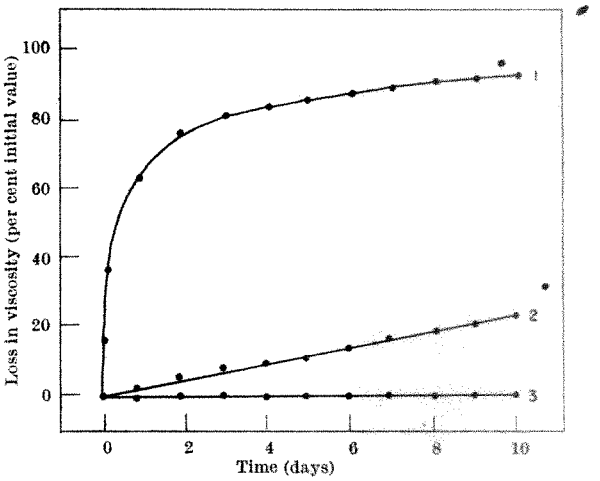

Fig. 1. Effect of pea epicotyl extract on viscosity of carboxymethylcellulose solution (CMC). Curve 1, 1·0 ml. purified extract added to 9·0 ml. 1·1 per cent CMC – 0·2 per cent NaF – 0·02 M phosphate *p*H 6·0 in an Ostwald–Cannon–Fenske viscometer incubated at 35° C; curve 2, boiled enzyme control; curve 3, water control. Viscosity calculated by the method of Nokrans and Hammarstrom (ref. 5)

which is proportional to the amount of extract added provided a boiled control is taken into account. After about one-third of the initial viscosity is lost, the rate declines and in time the solution approaches a stable viscosity near that of water.

The enzyme generates reducing power (Table 1), as determined by the copper method[5] for sugars, from both CMC and hydrocellulose (Whatman cellulose powder suspended briefly in 75 per cent sulphuric acid and washed exhaustively with water). The *p*H optimum is close to 6·0 for both reactions. Since less than 0·5 per cent of the potential reducing power in CMC is released by the time the solution loses 90 per cent of its viscosity (cf. Table 1 and Fig. 1), the polymer is apparently broken at points along the chain which are not terminal. In all these respects the enzyme acts as a typical cellulase.

Table 1. Enzyme Activity measured by Formation of Reducing Power

Time (days)	Reducing power increase over zero time (mg glucose equiv./ml. enzyme)	
	Carboxymethylcellulose solution*	Hydrocellulose suspension*
1	0·15	0·18
2	0·29	0·29
3	0·42	0·36
4	0·58	0·40
6	0·70	0·47
8	0·89	0·49

* Samples with 100 mg CMC as substrate per ml. enzyme were taken from experiment described in Fig. 1. With hydrocellulose, purified enzyme was passed through an ultrafine glass filter and 1·0 ml. pipetted aseptically to autoclaved tubes containing 90 mg substrate suspended in 4 ml. of 0·25 per cent sodium fluoride–0·025 M phosphate *p*H 6·0. Samples incubated with boiled enzyme formed 0·02 to 0·03 mg glucose equivalent in 8 days.

The relative amounts of cellulase activity which can be extracted from specific sections of the epicotyl are shown in Table 2. Expressed on a fresh-weight basis, extracts of sections from the apex or node yield much more activity than extracts from basal sections of the internode. The former group of sections delimits regions of cell division and potential growth (*PH* and *N*) and regions of active cell enlargement (1 and 2), while the latter contains regions of cells which differentiate but do not grow (4 and 5)[3]. Whether activities are re-calculated on a soluble protein basis or per unit dry weight of insoluble materials from which the extracts derived, all sections in the first group yield at least twice the activity of those in the second. The results appear to reflect real differences in enzyme level since we could find no evidence for cellulase inhibitors in any of the extracts, and tissue residues which are discarded during preparation of the enzyme yield no activity on further extraction with Na_2HPO_4, NaH_2PO_4, 20 per cent sodium chloride or sodium choleate.

Table 2. Cellulase Activity* in Extracts of Various Sections† of the Epicotyl

Section	Relative activity per unit fresh wt. Crude extract	Boiled extract	Difference (enzymatic)
PH	39·1	1·3	37·8
1	17·6	2·1	15·5
2	12·9	2·0	10·9
3	8·6	2·1	6·5
4	5·4	2·2	3·2
5	2·7	2·0	0·7
N	11·8	1·5	10·3

* Activity is expressed as percentage loss in viscosity of 1 per cent CMC solution caused by extract derived from 0·23 g fresh wt. tissue in 24 h; conditions as in Fig. 1.

† Sections used were the plumule plus hook (*PH*), 5 mm segments of the third internode (1–5 from apex) and a segment bearing the second node (*N*)[5].

There are obvious dangers in projecting the results of cellulase concentration investigations *in vitro* to effects on cellulose fibrils *in vivo*. However, there is more than usual justification for doing so here because the pea epicotyl is one of the few plant tissues for which there is physiological evidence of a metabolic turnover of cell wall materials. Those epicotyl sections which showed most active wall breakdown[3] are those which yield highest cellulase activity (Table 2). The association of both activities with growing or potentially growing tissue recalls Tracey's 1950 report[4] of a cellulase concentrated in the youngest parts of tobacco leaves and roots, and his recent suggestion[4] that the enzyme may "play a role in the remodelling of the primary cell wall during growth". Certainly a loosening effect on the cellulose framework is a real possibility if further investigation confirms that the enzyme breaks the hexose polymer internally. It may be that cellulase action permits growth by maintaining the cell walls in a plastic and extendable state, and that with time, loss of cellulase and continued cellulose deposition, the walls eventually become too rigid for cell expansion to take place.

PHYSIOLOGY

Effect of Rhinencephalic Lesions on Cardiovascular Reactions to Noradrenaline

It had been observed in the course of previous investigations on pharmaco-dynamic dissociations between central and peripheral effects of catecholamines[1] that paradoxical cardiovascular responses to intravenously injected noradrenaline frequently occurred in rabbits with more or less important forebrain lesions. These observations suggested a series of experiments designed to assess eventual causal relations between both phenomena.

The experiments described here were carried out on 50 male adult rabbits carefully selected from the same source ('Fauves de Bourgogne'). The animals were anæsthetized lightly with ethyl-urethane. The head was fixed with the help of a special head-holder[2] in a standard Horsley-Clarke carriage. Blood pressure in the left femoral artery was measured with a mercury manometer throughout, and single-channel electrocardiographic tracings (*D*-3) were recorded prior to and after an intravenous administration of 2·5 μg of noradrenaline bitartrate, cerebral lesions were then made, and *D*-3 tracings again recorded before and after a second injection of the same dose of noradrenaline. The lesions were performed by coagulation through the tip of stereotaxically oriented electrodes, according to the (slightly modified) co-ordinates of Sawyer, Everett and Green[3]. The position of the electrodes was controlled by histological examination.

It is well known that the adrenergic transmitter engenders transient hypertensive effects, and that high concentrations of that substance occasionally initiate ectopic heart rhythms. We found that an immediate and definite deterioration of blood pressure and electrocardiographic reactions regularly occurred after a single injection of 2·5 μg of noradrenaline bitartrate whenever a bilateral symmetric lesion was made at the anterior basal part of the rhinencephalon (close to the anterior commissure at the level of the olfactory tubercle). Our preliminary experiments also showed that less-severe cardiac irregularities (bigeminal and trigeminal ventricular extrasystoles) may appear after a sequence of about ten intravenous injections of our small standard dose of noradrenaline at intervals of 5 min. But such aberrant results were only obtained in one case out of ten.

The experiment illustrated in Fig. 1 shows that a successfully operated animal responds to the transmitter with an abrupt, irregular and long-lasting hypotensive reaction. This sudden reversal is generally paralleled by progressive pathological alterations shown on the corresponding electrocardiogram. As can be seen from Fig. 2, the same dose of noradrenaline which leaves the ECG of the normal animal practically unchanged induces the appearance of abnormal components after the cerebral lesion (intervening between *A* and *B*). The tracing now shows an outburst of ventricular extrasystoles and becomes more and more anarchic, finally leading to a transformation of the S-T complex into the 'dome-waves' of Pardie (*D*), that is, into manifestations which remind one of the primary phase of human myocardial infarction.

Another experiment (Fig. 3) reveals a still more dramatic development of aberrant complexes. The heart rate of the rabbit changes from 220 (normal rate) to a supraventricular tachycardia of about 300, finally involving the presence of inverted *T*-waves (see *F*) such as generally characterize the second, ischæmic, phase of infarction. It seems particularly interesting that such far-reaching pathological effects can be caused by minute amounts of the adrenergic transmitter corresponding to 2·5 μg of noradrenaline bitartrate or to 1·2 μg of noradrenaline base, in an animal of the weight of 3 kg, that is, by a dose which might be considered as physiological.

A macroscopic exploration of the cardiac cavities of such an animal shows the presence of diffuse subendocardial hæmorrhages in the walls and valves of the left ventricle. Parietal petecchies are visible at the atria and

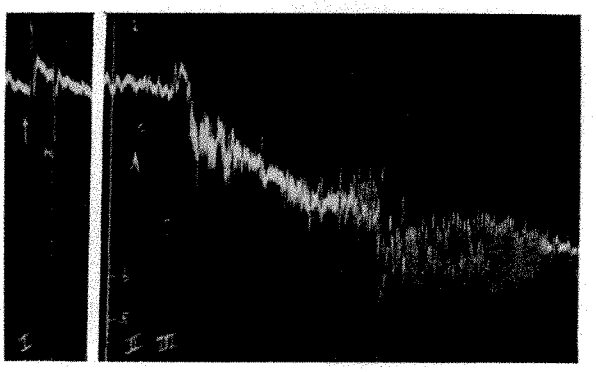

Fig. 1. Rabbit blood pressure : effects of intravenous injections of 2·5 μg of noradrenaline bitartrate ; between (I) and (II), at the arrow : symmetrical bilateral lesion at the base of the anterior rhinencephalon

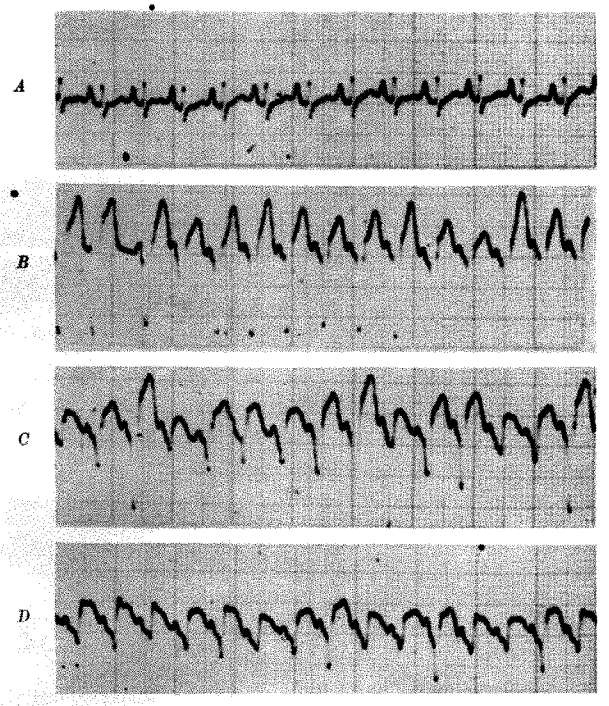

Fig. 2. Electrocardiographic tracings (*D*-3) of the same animal. *A*, normal reaction to 2·5 μg of noradrenaline bitartrate; between *A* and *B*, rhinencephalic lesion; at *B*, injection of the same dose of noradrenaline bitartrate; from *B* to *D*, progressive deterioration of the ECG

intra-atrial connexions. The rhinencephalic lesion apparently induces a facilitation of the action of noradrenaline on excitable tissue sites of the heart, and the resulting ruptures of intracardial vessels by the same agent may be the final cause of the observed functional disturbances.

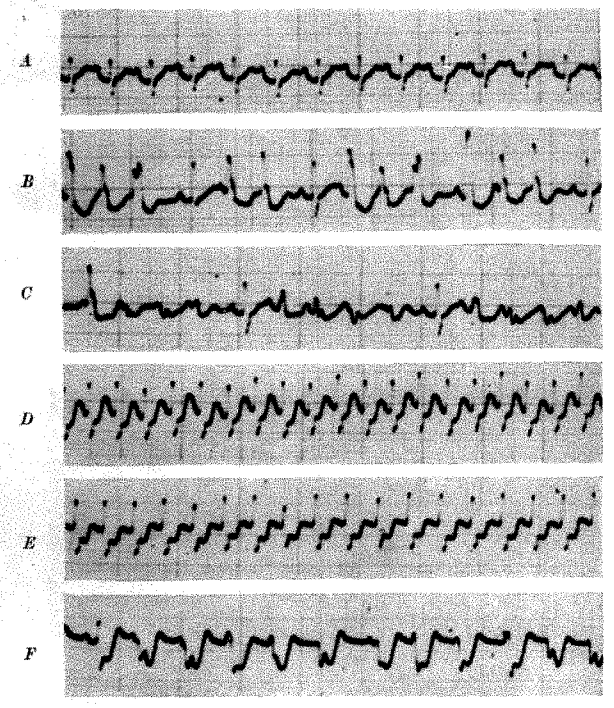

Fig. 3. Electrocardiogram of a rabbit. At *A*, normal response to the intravenous injection of 2·5 μg of noradrenaline bitartrate; between *A* and *B*, bilateral rhinencephalic lesion; from *B* to *F*, aberrant reactions to an intravenous injection of the same dose of noradrenaline made at *B*

Interpretation of these results, however, should take into account the fact that the same noradrenaline which accelerates the isolated heart engenders bradycardia when injected into the systemic circulation of animals. This latter reaction is probably due to the intervention of cholinergic regulation mechanisms. The lesion may thus eliminate, directly or through the interruption of afferent or efferent fibres, a centre that effectively controls the sympathetic supply of the heart. An impairment of the anterior basal part of the rhinencephalon may then lead to a parasympathetic disconnexion of that organ which becomes particularly sensitive to more or less excessive adrenergic impulses.

The rhinencephalon forms a physiological entity which includes not only the olfactory tracts and their main termination sites, but also such diverse structures as the hippocampus, cingulate gyrus, retrosplenial cortex, hypothalamus, parts of the thalamus, the habenular nucleus which is relayed to the pineal body, the fasciculus retroflexus, the amygdaloid nuclei and the mammillary bodies. This complex is involved in the cerebral control apparatus of psychosomatic correlations. Emotion as well as any other kind of mental stress is supposed to activate the adrenergic emergency reaction. It is tempting to put forward, as a working hypothesis, therefore, that the coincidence of the special rhinencephalic lesion and the observed sensitization of the heart to an adrenergic agent of the noradrenaline type, possibly released during a psychogenic shock, may create a condition similar to that which induces human myocardial infarction.

Recent (unpublished) findings in our laboratory indicate, on the other hand, that animals submitted to identical bilateral rhinencephalic lesions and showing the aforementioned aberrant cardiovascular responses to intravenous noradrenaline are still capable of reacting to the stimulation of a hypothalamic centre (located at the latero-medial part of the hypothalamus). When they are so stimulated, the systemic blood pressure rises, and this reaction, moreover, initiates a remarkable improvement of heart activity.

Membrane Potential of Electrolyte-depleted Muscle Fibres

Koketsu and Kimura[1] have reported experiments in which the potassium concentration within frog muscle fibres $[K]_i$ was reduced by soaking sartorii in hypotonic sucrose solutions. They found that, although $[K]_i$ was reduced from 130 to about 48 m.equiv./l. fibre water by this procedure, the membrane potential of the fibres measured in normal Ringer's fluid by the micro-electrode technique was not decreased. It remained at about 93 mV, in spite of the fact that the potassium-equilibrium potential E_K was then only 80 mV. They concluded that the results did not favour the ionic theory of membrane potential[2–4]. Ling also quoted these experiments[5] as evidence against the membrane theory.

It seemed likely to us that the Cl^- distribution across the cell membrane might contribute significantly to the membrane potential here, particularly as the chloride equilibrium potential E_{Cl} might be expected to increase as the intracellular chloride concentration $[Cl]_i$ was reduced during immersion of the muscles in sucrose.

We soaked frog sartorii for 6 h in sucrose and then transferred to a normal[3] and then to a chloride-free Ringer's fluid for membrane potential measurement. In the latter the sodium chloride was replaced by sodium methylsulphate, and K^+ was present as 2·5 mM potassium bicarbonate. Following potassium analysis of the muscles E_K was calculated. The results are summarized in Table 1.

Table 1

$[K]_o$ (mM)	$[K]_i$	E_K (mV)	E_m (mV) With Cl	E_m (mV) Without Cl
2·5	38·8	69·0	98·1 ± 1·9	65·2 ± 1·3

In another series of experiments muscles were soaked in sucrose for 3 h until the mean intracellular concentration had been reduced from about 130 to 79 m.equiv./l. fibre water. These muscles were re-immersed in chloride-free fluid containing 2·5, 10 and 25 mM potassium bicarbonate and the mean membrane potential was measured by the micro-electrode. From the overall mean $[K]_i$ of the muscles, the theoretical E_K was calculated for the various $[K]_o$ used and was plotted as a straight line (Fig. 1). The potentials measured are also plotted in Fig. 1 against the log of the external potassium concentration. It can be seen that within the limits of experimental error there is reasonable agreement between the observed and calculated potentials over the range examined when Cl^- is absent from the external fluid.

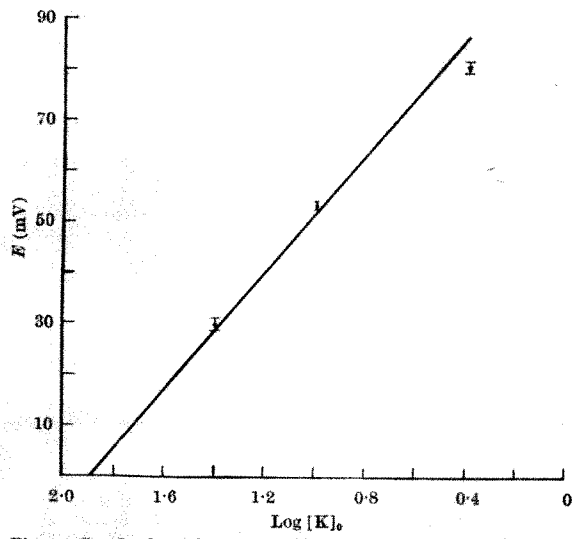

Fig. 1. Graph of membrane potential of muscle plotted against the log of the external potassium concentration. The line represents the calculated potassium-equilibrium potential for a mean internal potassium concentration of 79 m.equiv./l. fibre water. The points represent mean measured potentials and the standard errors are shown by barred lines. Potentials were measured in chloride-free Ringer with 2·5, 10 and 25 mM potassium respectively.

It appears then that Cl^- contributes to the membrane potential following depletion of intracellular K^+ and Cl^-, but that, in the absence of external Cl^-, the membrane potential is determined mainly by the concentrations of K^+ within the muscle fibres and in the external fluid. It is concluded that these findings are quite in keeping with the membrane theory.

I thank Prof. E. J. Conway for his advice, Miss Aileen Tangney for her assistance and the Medical Research Council of Ireland for a fellowship.

Exocrine Secretion from the isolated Rabbit Pancreas

Study of the mechanisms of secretion of the digestive glands has been handicapped by an inability to isolate the glands from the influence of variable control mechanisms such as blood flow, nervous factors and humoral agents. In the work recorded here it was possible to maintain pancreatic secretion in an *in vitro* preparation of rabbit pancreas for 5–6 h and to demonstrate ion concentration-flow relationships similar to those found *in vivo*. Adequate oxygenation of the organ is possible because the pancreas of the rabbit is nearly as thin as the surrounding mesentery (about 0·2 mm). It is entirely located within the mesomentum of the first duodenal loop. The collecting duct enters the duodenum completely separated from the common bile duct, and thus is easily identified and isolated.

The pancreatic duct was cannulated *in situ* with polyethylene tubing (0·61 mm outer diam.). The entire mesomentum included in a duodenal loop extending from the gastroduodenal junction aborally 30–40 cm was removed as a unit[1]. The mesomental loop was then mounted on a 'Plexiglas' frame using stainless steel hooks attached to the duodenum, and the frame was placed in a 'Plexiglas' chamber with the catheter draining dependently to the outside (Fig. 1). The organ was bathed in a balanced salt solution (118·5 mM/l. NaCl; 4·75 mM/l. KCl; 2·54 mM/l. $CaCl_2$; 1·18 mM/l. KH_2PO_4; 1·18 mM/l. $MgCl_2$; 24·9 mM/l. $NaHCO_3$), maintained at 30° C and gassed continuously with 95 per cent oxygen and 5 per cent carbon dioxide. Mounting required 10–20 min. Chloride concentration was determined coulometrically, and total carbon dioxide concentration with the Van Slyke and Plazin micromanometric technique. Eighteen New Zealand white rabbits weighing 1·8–2·4 kg were used in this experiment.

Pancreatic secretion varied from 28 μl./h to 561 μl./h. The most rapid rates *in vitro* were comparable to *in situ* flows obtained by Baxter[2,3], as well as to *in situ* secretin-stimulated flows obtained in this laboratory. While flow varied with different preparations, it was relatively constant for a given preparation up to at least five hours after isolation.

Flow was inhibited when the oxygen–carbon dioxide gassing mixture was replaced with 95 per cent nitrogen

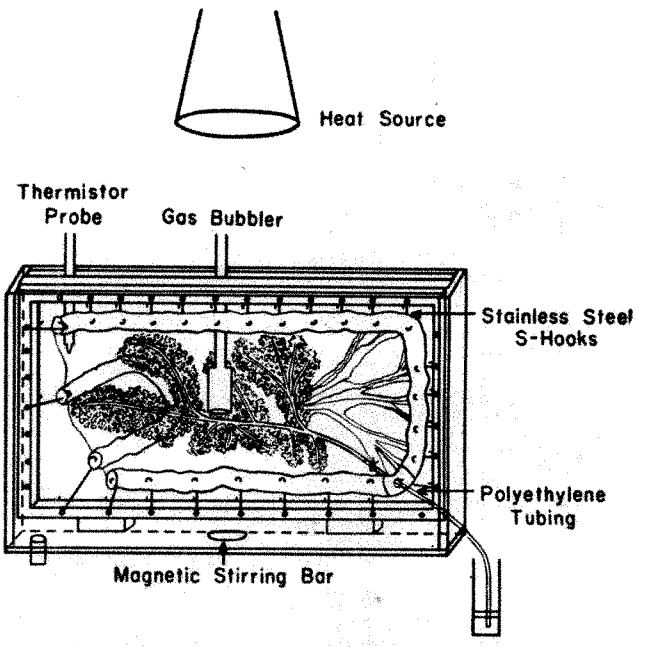

Fig. 1. Schematic diagram of rabbit pancreas and duodenum suspended in chamber (175 ml. vol.)

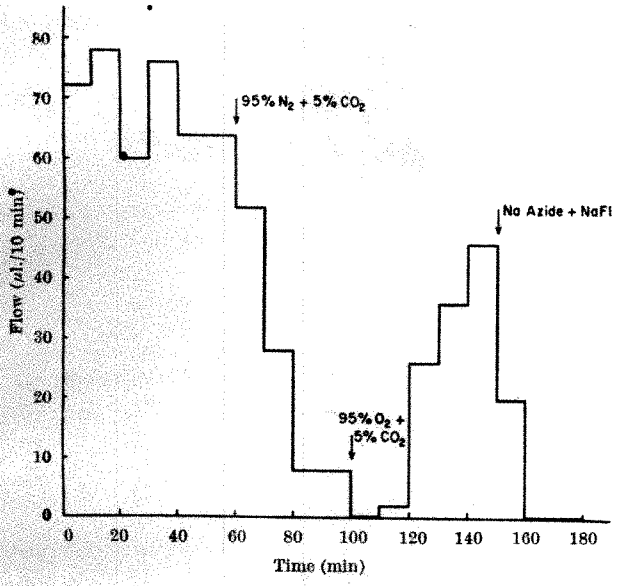

Fig. 2. Metabolic dependence of *in vitro* rabbit pancreatic secretion. Time zero represents 4 h after the gland started secreting *in vitro*. The mean flow for the preceding 4 h was 74·6 μl./10 min

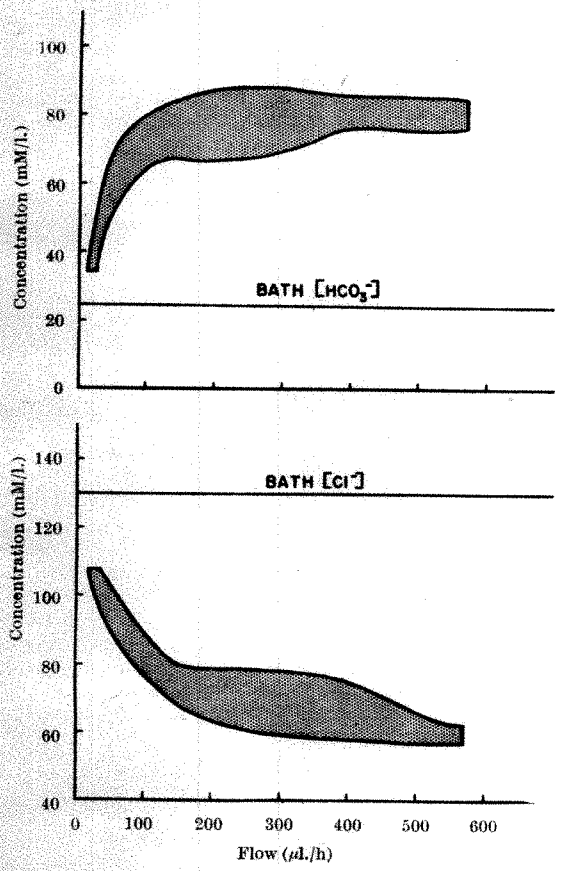

Fig. 3. Flow-concentration relations for total carbon dioxide (above) and chloride ion (below). Curves shown are the envelopes of the observed points

and 5 per cent carbon dioxide (Fig. 2). The addition of sodium fluoride and sodium azide to the fluid invariably produced complete cessation of flow within ten to twenty minutes.

Juice bicarbonate concentrations have been obtained *in vitro* up to four times the bath bicarbonate concentration. The flow-concentration curves are similar to those found in man and chronic fistula dogs, although the values of Fig. 3 apparently approach an asymptote at approximately 76–88 mM/l. for bicarbonate, whereas those for man and dog reach a plateau approximately at isotonicity with plasma, namely, 140 mM/l.[4,5]. *In situ* investigations with rabbits show a slightly higher plateau concentration than those obtained *in vitro* (90–100 mM/l.). The sum of the bicarbonate and chloride ion concentration was relatively constant with a mean of 146·1 mM/l. (range 132·0–164·6 mM/l.) as has been found in man and dog[4,5].

Davenport[6] has pointed out, on the basis of the large discrepancy between oxygen consumption and the possible potential energy supplied by the blood pressure, the relatively minor importance of perfusion pressure in supplying energy for secretion in this organ. The observation that in the absence of blood perfusing pressure as an energy source the pancreas can secrete a fluid of volume and ionic content comparable to that found *in situ* supports his conclusion. The mean 'basal' secretory rate *in vivo* in the fasted, anæsthetized rabbit over a 4-h period (excluding the 1st h after cannulation) was 59·4 μl./h, whereas the mean flow in the *in vitro* preparation taken from similarly fasted animals was 303·5 μl./h over the same period. The low flows obtained *in situ* may be due to a net inhibitory tone (nervous or hormonal) affecting the organ.

Apparently mammalian digestive glands, with the exception of the gastric glands, have only been studied *in vitro* with the aid of tissue-sectioning techniques. The present technique, therefore, may offer new opportunities for the study of peripheral control mechanisms of pancreatic secretion as well as for the study of cellular mechanisms of secretion from tubulo-alveolar secretory glands.

PHARMACOLOGY

Mercury in Mouse Brain after Inhalation of Mercury Vapour and after Intravenous Injection of Mercury Salt

The question of whether or not exposure to mercury vapour is equivalent to parenteral administration of mercuric ions for tissue accumulation is of great importance when evaluating experimental results for the purpose of setting threshold limits for mercury in ambient air. Clarkson *et al.*[1] showed that mercury vapour is rapidly oxidized to mercury ions in the erythrocytes of the blood.

In experiments on rats, Hayes and Rothstein[2] found no difference in the proportional distribution of mercury after exposure to the vapour as compared with intravenous injection of mercury salt. However, they did not state the amount of mercury found in the brain. Clinical observers have reported[3] that after acute exposure to mercury vapour, the dominant toxic symptoms arise in the respiratory tract and the central nervous system, while renal damage is less conspicuous or not detectable.

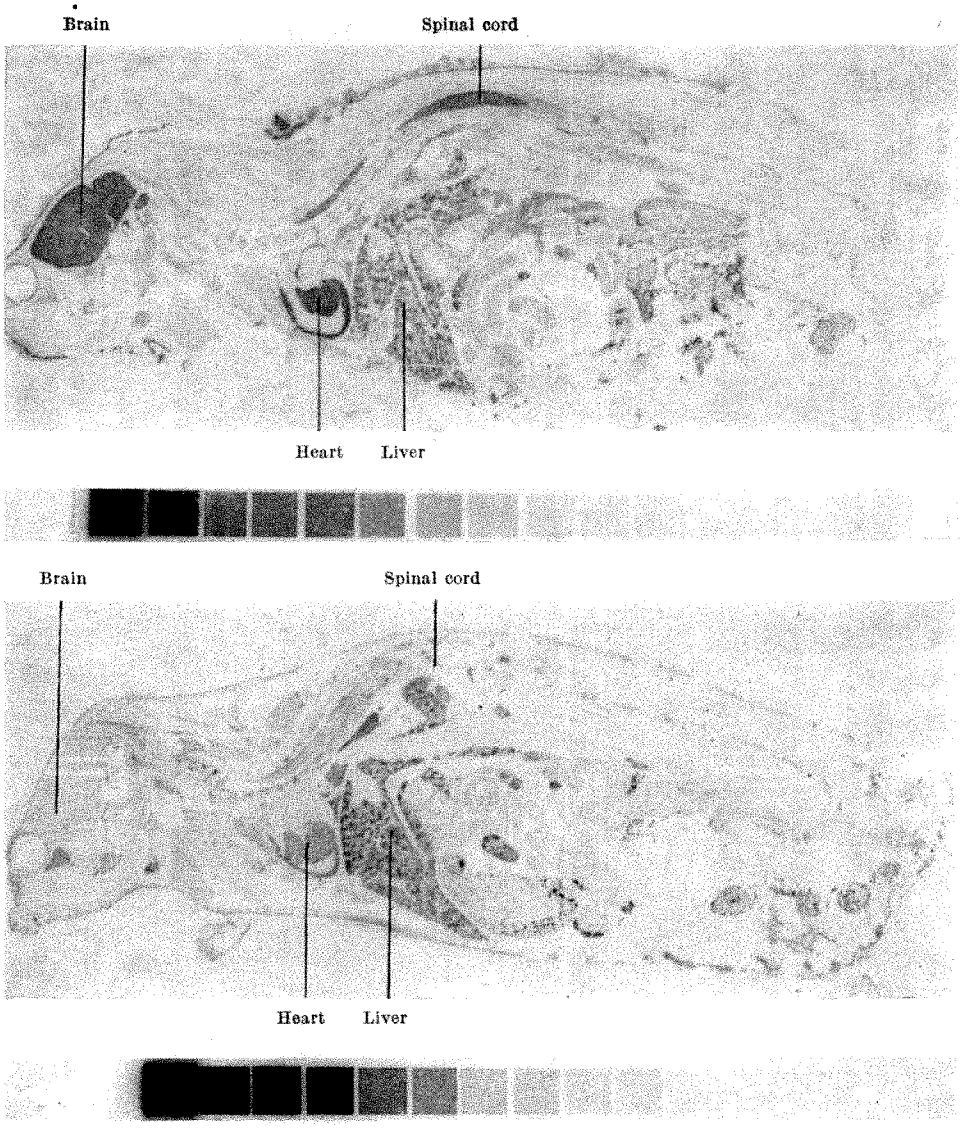

Fig. 1. Autoradiograms of distribution of mercury in whole-body sagittal sections of mice 8 days after inhalation of mercury vapour (upper), and after injection of mercury nitrate (lower). Below each section is the isotope standard 'staircase' autoradiographed on the same film

This is in contrast to the findings in acute sublimate intoxication, where renal damage is dominant.

To elucidate this question further we have exposed mice to radioactive mercury vapour, 10 mg/m³ of air, for 4 h. Immediately after exposure the amount of mercury absorbed was estimated in the living mouse by means of a body scintillation counter. A similar dose of radioactive mercury in the form of mercuric nitrate was then injected into the tail vein of another, similar mouse, so that for every animal exposed to the vapour there was one animal injected with the salt.

At predetermined intervals of 1 h–32 days after exposure, the paired animals were killed. 'Whole-body' autoradiography was performed on a half of each animal and the mercury concentration in the organs was determined by densitometric comparison with an isotopic standard 'staircase'[4]. From the other half of each animal the brain, liver, kidney and other organs were taken for mercury assay by scintillation count.

The autoradiograms revealed that the uptake of mercury in the brain was about ten times greater in the animal which had inhaled mercury vapour than in the animal which had received a similar dose intravenously. Fig. 1 shows the autoradiograms of sagittal sections of mice killed 8 days after inhalation of mercury vapour (upper) or injection of mercuric nitrate (lower). The increased amount of mercury in the brain of the vapour-exposed animal is well illustrated. The 'staircase' beneath the sections show the density of decreasing concentrations of isotope in a dilution series (1/1, 1/2, 1/4, 1/8, etc.). The findings were confirmed by determination of the mercury in the corresponding brain halves by scintillation count. Detailed reports of the studies referred to here will be published elsewhere.

HÆMATOLOGY

Differential Plasma Turbidity as an Index of Platelet Count

RECENT work on the assay of platelet aggregation in platelet-rich plasma (P.R.P.) using a turbidimetric method[1,2] suggested the possibility that this simple technique might be adapted to give a direct measure of the platelet count of plasma.

Use of this principle was reported by Cruz[3]. His method involved the initial separation of the platelets, which were then washed and re-suspended in sodium citrate. The turbidity of this suspension was found to correlate well with the platelet volume as determined by the thrombocytocrit method of Van Allen[4]. The error of repeated turbidimetry on the same sample was about 6 per cent.

In order to simplify the procedure and to minimize the manipulation of the platelets, the technique used in this work was to measure the turbidity of serial dilutions of platelet-rich plasma against a blank of platelet-poor plasma (P.P.P.) from the same subject. P.P.P. was used as a diluent in preparing each concentration of P.R.P.

Venous blood samples were taken from 10 normal subjects (five male and five female) and transferred to a centrifuge tube containing 1/10 vol. of 3·8 per cent sodium citrate. A silicone technique was used throughout the entire procedure. After centrifugation at 1,000 r.p.m. for 10 min, the P.R.P. was removed. The remainder of the sample was centrifuged at 3,000 r.p.m. for 20 min to obtain P.P.P. Dilutions of P.R.P. were made with P.P.P. in 10 per cent steps from 100 per cent down to 10 per cent. However, at the two highest dilutions the error of the estimate was so high that they had to be discarded. The results are, therefore, given for the eight dilutions from 100 per cent to 30 per cent.

The turbidimetric measurements were made on a Unicam *S.P.* 600 spectrophotometer at a wave-length of 600 mμ using the 2-mm cells. Platelet counts were made in duplicate on samples from each dilution of P.R.P. and expressed as cells per mm³. The value log platelet count/turbidity × 10^5 was known as the turbidity index.

With this experimental design it was possible to test: (*a*) whether for any individual the differential turbidity between P.R.P. and P.P.P. was an accurate measure of the platelet count at all dilutions; (*b*) whether the turbidity index was tolerably constant from one individual to another.

Table 1 shows the analysis of the turbidity indices for each dilution in the whole group of 10 subjects. Analysis of variance showed homogeneity of the groups when separated in this way, that is, the dilution technique did not significantly affect the turbidity index. However, the variance of the individual results at any given dilution was found to be quite large. Thus the 95 per cent confidence limits for the mean value of 1·126 estimated for undiluted P.R.P. samples lie between 1·194 and 1·058, representing a range of ratios between 11·43 and 15·63. This is clearly too wide for the turbidity index to be regarded as an accurate assay of plasma platelet count in any group of individuals.

Table 1. MEAN VALUES OF LOG PLATELET COUNT/TURBIDITY × 10^5 FOR EACH DILUTION OF PLATELET-RICH PLASMA

Dilution (%)	100	90	80	70	60	50	40	30
Mean	1·126	1·096	1·082	1·087	1·114	1·147	1·161	1·197
S.D.	0·096	0·099	0·109	0·097	0·117	0·134	0·133	0·154
S.E.	0·030	0·031	0·034	0·031	0·032	0·042	0·042	0·049

Table 2. MEAN VALUES OF LOG PLATELET COUNT/TURBIDITY × 10^5 FOR EACH SUBJECT

Subject No.	1	2	3	4	5	6	7	8	9	10
Mean	1·204	1·356	1·131	1·009	1·109	1·034	1·173	1·006	1·192	1·047
S.D.	0·046	0·103	0·068	0·036	0·056	0·061	0·080	0·049	0·028	0·047
S.E.	0·016	0·036	0·024	0·012	0·020	0·022	0·028	0·017	0·009	0·017
Turbidity readings of P.P.P.	0·020	0·145	0·022	0·040	0·055	0·085	0·065	0·014	0·032	0·015

Another variable to be considered is the turbidity of the platelet-poor plasma used as a blank. The values for these as measured against distilled water are recorded in the bottom row of Table 2. It will be seen that the highest values for both the mean turbidity index and the P.P.P. turbidity are found in subject No. 2, and the lowest in subject No. 8. In the numbers used, the correlation between these two parameters was, however, quite insignificant. It is possible that a larger group with a wider range of P.P.P. turbidities would have shown such relationship, but this has not been tested.

Table 2 shows the results derived from each subject for the eight dilutions of P.R.P. It can be seen that the standard errors are small. Thus it appears that if the platelet count of the original specimen and its turbidity are known, subsequent turbidity measurements can be expected to give a reasonably accurate estimate of changes in the platelet count.

Analysis of variance reveals non-homogeneity of the data when grouped in this way ($F = 3·18$; P less than 0·01). This confirms the conclusion already reached from the analysis in Table 1 that the turbidity index is not sufficiently constant from one individual to another for the method to be of value as an alternative to direct counting techniques.

Anthropological Observations of Blood Groups in Hiroshima

THE distribution of a number of human blood groups has now been established in many parts of the world[1].

Since the blood group antigen Di^a was found by Layrisse *et al.*[2] in Venezuela following a preliminary report of Levine *et al.*[3], we became interested in investigating the distribution of this factor in different populations. The Di^a antigen is found in 36 per cent of South American Indians and the factor is also present in Mongolians with a lower incidence. However, the presence of the Di^a antigen in Caucasians is presumably very rare.

The frequency of the Diego factor in Japanese in Japan has been reported by several authors[4–7], and the results indicate that the distribution of the Di^a antigen was between 2·3 and 4·1 per cent in the Tokyo area and 7·5 per cent in the southern part of Japan.

Recently, we investigated the frequency of the Diego (Di^a) factor together with the ABO, MN and Rh_0(D) blood antigens in three villages, Mukaihara, Yoshida and Miyoshi, situated in the northern part of Hiroshima Prefecture. These areas were selected particularly because of the isolated conditions under which the people in these villages were living. In addition to blood group distribution, the population offered other avenues of anthropological research.

The investigations were carried out with high-school students classified on genetic grounds into two groups. One group had been living in the area for more than three generations and had intermarried only with other members of the three villages, called non-mixed group; in the other group, either one or more people had entered the area

from another part of Hiroshima Prefecture within the past three generations, called mixed group.

In the work recorded here, the distribution of the blood groups in the two classes was compared for significant differences.

5 ml. of venous blood was collected in acid citrate dextrose (ACD) solution obtained from the Hiroshima Blood Bank. The ACD solution conformed to the minimum requirements of the N.I.H. of Japan. Red blood cells were washed three times with physiological saline and used as 2 per cent saline suspensions for agglutination.

ABO and MN blood typing sera, conforming to N.I.H. minimum requirements, were also obtained from the Hiroshima Blood Bank. Anti-Rh_0(D) was obtained from Knickerbocker Biologicals, Inc., New York.

ABO and MN typing was carried out at 25° C by direct saline agglutination tests; Rh_0(D) and Diego blood typing were performed at 37° C by the antiglobulin test using antiglobulin sera obtained from Hiroshima Blood Bank.

The results of the present investigation showed the frequency of group B to be higher in the areas under investigation as compared with the national population frequency (Table 1). The frequency of group AB was higher in the non-mixed group than in either the mixed group or the national population. On the other hand, group A and group O appeared to have a lower frequency in the two groups as opposed to the national figures. However, there was no discrepancy in the order of frequency of the two groups, or the national population: A > O > B > AB.

No differences in the distribution of the MN groups were noted in this work.

Table 1. Frequency of ABO, MN, Rh_0(D) and Diego (Di^a) Blood Groups in the Northern Part of Hiroshima

Classification	No. tested	Percentage observed			
		O	A	B	AB
Non-mixed group	1,125	28·53 ± 1·35	39·29 ± 1·46	21·51 ± 1·22	10·67 ± 0·92
Mixed group	508	31·10 ± 2·05	36·81 ± 2·14	23·23 ± 1·87	8·86 ± 1·26
		M	N		MN
Non-mixed group	1,125	33·24 ± 1·40	14·93 ± 1·06		51·82 ± 1·49
Mixed group	508	31·89 ± 2·07	17·13 ± 1·76		50·98 ± 2·22
		Rh_0 (+)		Rh_0 (−)	
Non-mixed group	1,125	99·82 ± 0·13		0·18 ± 0·13	
Mixed group	508	100·00		0·0	
		Di (a+)		Di (a−)	
Non-mixed group	309	8·09 ± 1·55		91·91 ± 1·55	

It is known that the frequency of Rh-negative individuals is quite low in Japan as compared with white populations, based on the investigations of Furuhata *et al.* The present investigations showed only 0·18 per cent in the non-mixed group and none in the mixed group.

Unfortunately the anti-Di^a serum was not suitable for testing all blood samples, and the tests, therefore, were only carried out on the non-mixed group. In this work, 8·09 per cent were found to be Diego positive.

The results of the ABO distribution suggested that a higher proportion of the B factor was found in the mixed group than in national distribution. On the other hand, the O factor and the A factor occurred with a lower frequency in the non-mixed group and in the mixed group respectively than in the others. In addition, the frequency of Rh_0(D) negative persons was slightly lower than in the report of Furuhata *et al.* The Diego factor was found to occur with a somewhat higher frequency but was in essential agreement with the findings of Yokoyama *et al.*, who have observed that the distribution of the Diego factor gradually increases from the northern to the southern part of Japan.

A higher incidence of group B, Rh_0(D) positive and Diego(Di^a) positive factors assures their position as Asiatic characters judged from an anthropological point of view.

We thank Dr. M. Layrisse, Caracas, Venezuela, for supplying the anti-Diego serum used in this work.

Glucose-6-phosphate Dehydrogenase Deficiency in Indonesia

Glucose-6-phosphate dehydrogenase deficiency has been reported from Singapore[1], India[2], Malaya[3] and Thailand[4]. It has not been reported from Indonesia, although cases of hæmolytic anæmia due to the ingestion of drugs are known to occur.

It is therefore of interest to report the findings of a preliminary investigation of G-6-P dehydrogenase among Indonesians living in Djakarta, Indonesia.

The methods used were the dye test of Motulsky and Campbell[5] and the methæmoglobin reduction test of Brewer *et al.*[6]. A clearing time of more than 100 min was taken as abnormal for the test of Motulsky and Campbell. It was later realized that the clearing time was longer than 120 min in deficient persons. It was therefore considered necessary to follow up the test for at least 2 h in abnormal people. The clearing time was less than 90 min in normals and was usually 40–70 min. The Indonesians living in Djakarta originate from different parts of Indonesia but most of them are from west Java. Only males were examined, since the Motulsky test is not suitable for the detection of female carriers. 368 normal healthy Indonesians (laboratory workers, students and blood donors) and 78 Indonesian patients of the General Hospital medical wards were examined. 81 of the normal healthy persons were examined by the methæmoglobin reduction test; the rest were examined by the Motulsky and Campbell test. Results of the work are listed in Table 1.

Table 1

	No. examined	Deficient
Normals	368	5
Patients	78	0
Total	446	5 (=1·1%)

The frequency of 1·1 per cent is at the lower side as compared with the findings in other racial groups in Asia. A frequency of 2·5 per cent was found in normal healthy Chinese in Singapore and Malaya. In healthy Malays the frequency was 0·6 per cent for Singapore and 2 per cent for Malaya. The frequency in Indians has been found to range between 0·6 and 7 per cent[1–3,5,7]. In Malayan aborigines, high frequencies of more than 20 per cent were found in certain tribes. Higher frequency figures were also reported

from Thailand, where Kruatachue *et al.*[4] found a frequency of 14 per cent. Motulsky[5] found a frequency of 12·7 per cent in Philippinos. In the northern parts of Borneo frequencies of more than 6 per cent and up to 30 per cent in certain aboriginal tribes were found (Lie-Injo Luan Eng, unpublished).

The frequencies of G-6-P dehydrogenase in Djakarta, Singapore, Malaya and Thailand show a correlation with the frequencies of hæmoglobin E. The frequency of hæmoglobin E is low in Djakarta (2·5 per cent), high in Thailand and moderate in Singapore and Malaya (5 per cent). It is very high in the Malayan aborigines (30 per cent)[1,8]. This is higher than in many areas in Thailand. More or less parallel frequency figures have been found for G-6-P dehydrogenase. Similar positive correlations of frequencies for G-6-P dehydrogenase and hæmoglobin S or thalassæmia have been found in Africa and Sardinia[5,9]. Also a parallelism between G-6-P dehydrogenase frequencies and abnormal hæmoglobins has been demonstrated in Greece by Allison *et al.*[10]. It is suggested that this positive correlation would be expected if all the genes were favoured by malarial selection.

We thank all volunteers who have given their blood for examination and the Red Cross, Blood Transfusion Service, Djakarta, for the blood samples.

IMMUNOLOGY

A Micro-slide Method permitting Autoradiography of Hæmolysin-producing Cells

THE immune response to a single injection of sheep erythrocytes has been widely used in investigations of the primary antibody response. Recently, Jerne *et al.*[1] have widened the potentialities of this experimental model by a method for identification and enumeration of hæmolysin-producing cells (the agar-plaque technique). Cells from a hæmolysin-producing lymphoid organ are mixed and incubated at 37° C with sheep erythrocytes in an agar medium. After addition of complement, hæmolysis occurs in zones around cells from which antibody has diffused into the medium. A similar method has been described by Ingraham[2]. The following modification of the agar-plague technique enables tracing of radioactive isotopes to hæmolysin-producing cells by autoradiography.

The agar used is rendered non-anticomplementary with di-ethyl-amino-ethyl-dextran[3] as follows. 2 mg of DEAE-dextran (made from dextran with mol. wt. around 2×10^6; nitrogen content 3·2 per cent; sulphate ash < 1 per cent (Pharmacia, Uppsala, Sweden)) are dissolved in 100 ml. of a doubly concentrated Eagle's medium[4]. At 60° C one part of this solution is mixed with an equal part of 5·6 per cent agar ('Noble-agar', Difco). The precipitate is eliminated by centrifugation for 15 min at 3,000 r.p.m. at 45° C. A stock of this 2·8 per cent agar is kept at −20° C.

Carefully rinsed micro-slides are first covered with a layer of blood-agar. Melted 2·8 per cent agar and a 16 per cent suspension of sheep erythrocytes in Eagle's medium are kept in a water-bath at 45° C. 11 ml. of the erythrocyte suspension are mixed with 6 ml. of the agar solution in a glass cuvette placed in the water-bath. Micro-slides are dipped into the blood–agar mixture, allowed to drip off on cheese cloth for a second, wiped off with the cloth on one side, cooled on a metal plate for a few seconds, and then placed horizontally in a cool moist chamber. The moist chamber is then kept in the refrigerator until the glasses are used within a few hours.

The lymphoid cells to be tested are prepared by cutting lymph nodes or spleen with scissors into small fragments which are then passed through a fine metal mesh into Eagle's medium. Throughout the procedure (from excision of the organ up to the final mixing with agar) the cell material is kept strictly at 0° C. The cells are washed twice with Eagle's medium by centrifugation at 1,500 r.p.m. for 10 min and finally resuspended in a volume of Eagle's medium that gives a concentration of 4×10^7 cells/ml. The cell–agar mixture is prepared as follows. A tube containing 0·5 ml. of the cell suspension is heated for a few seconds in the 45° C water-bath. From this tube, 0·3 ml. are transferred to a glass cuvette (in the water-bath) containing a mixture of 10 ml. Eagle's medium and 3·6 ml. 2·8 per cent agar. The cell–agar suspension is mixed gently. The blood–agar slides, which 15 min earlier have been preheated by transfer to a moist chamber at 37° C, are rapidly dipped in the cell–agar suspension, allowed to drip off on cheese cloth for a second, wiped off on the blood–agar free side, and immediately placed horizontally in a cool moist chamber. The chamber is kept in the refrigerator for 15 min.

The blood–agar- and cell–agar-covered slides are then transferred to a moist chamber at 37° C and incubated at this temperature for 70 min. About 0·15 ml. of a good guinea-pig complement diluted 1 : 12 with Eagle's medium is then poured on the agar layer and kept in place with a

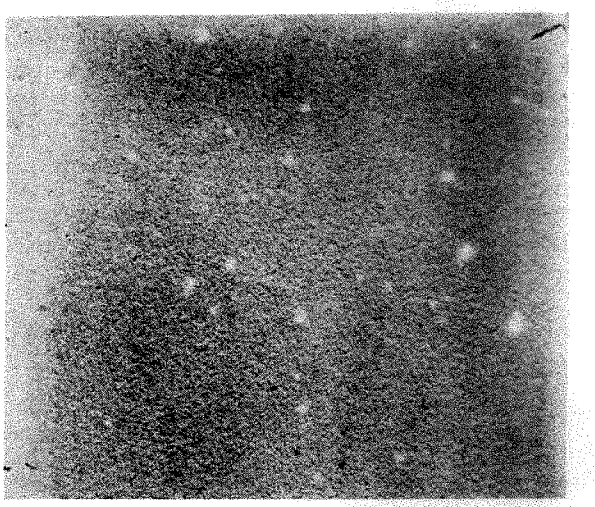

Fig. 1. Blood–agar-covered micro-slide with hæmolytic zones produced by mouse spleen cells (4 days after intravenous injection of sheep erythrocytes)

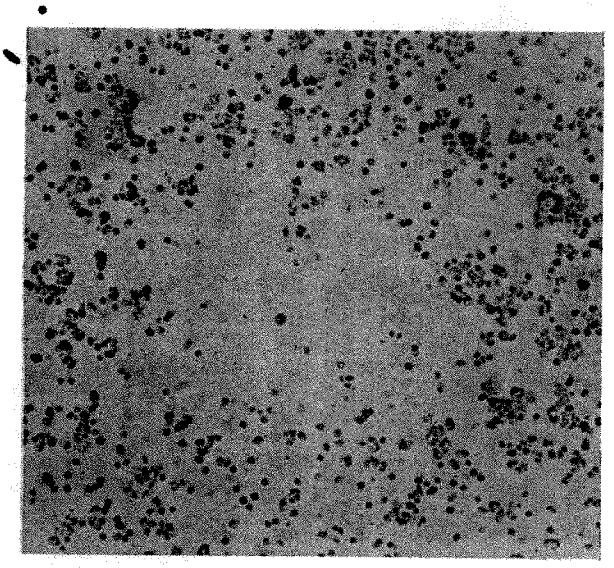

Fig. 2. Autoradiogram of a micro-slide preparation produced as indicated for Fig. 1. Low-power view of a hæmolytic zone with the central antibody-producing cell. The mouse had received tritiated thymidine intraperitoneally on the third post-immunization day

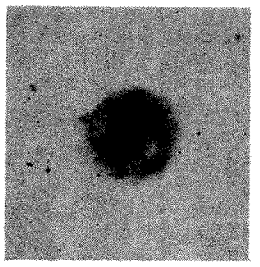

Fig. 3. High-power view of the central cell shown in Fig. 2. Five silver grains are located above the cell

cover-slip that covers the area containing lymphoid cells (about two-thirds of the slide). The slides are again incubated at 37° C for 40 min. The cover-slips are then gently slid off, and the complement is allowed to drip off for a few seconds. To protect the white cells during drying and fixation, the slides have to be washed by dripping about 0·2 ml. of a 1 : 6 dilution of serum (inactivated and absorbed with sheep erythrocytes) on the agar-covered area. As much as possible of the serum dilution is sucked off. The glasses are then dried by a cool fan for 1 h and finally fixed in methanol for 45 min. The hæmolytic zones are now easily detected by viewing the glasses through a low-power magnifier against a light source. It is advisable to encircle the zones on the back of the slide, using a diamond pencil. Slides incubated with inactivated complement may be used as controls. Figs. 1 and 2 show the macroscopical and microscopical appearance of the zones. The sheep-erythrocyte concentration used ensures fairly small but well-defined zones, which can be easily examined in the microscope. With more concentrated lymphoid-cell suspensions, more than one cell is often found in the centre of the zone and it is impossible to say which of them is the hæmolysin-producing cell.

The slides can be kept for a long time and used for histological investigation of the morphology of the antibody-producing cells. Sterzl and Mandel[5] have developed another modification of the agar-plaque technique, which also enables such investigations.

For autoradiographic tracing of tritiated thymidine to nuclei of hæmolysin-producing cells the methanol-fixed slides are first painted with egg-albumen–glycerol (1 : 1) on the margins of the agar layer and then coated with liquid autoradiographic emulsion (*K* 2 Ilford) by the method of Messier and Leblond[6].

After exposure, development and fixation, the slides are stained through the film with Giemsa by Gude's[7] technique.

Nature of the Normal Lymphocyte Transfer Reaction

The normal lymphocyte transfer (NLT) reaction is aroused when lymphocytes from one normal adult guinea-pig[1] or human being[2] are injected intradermally into another normal adult guinea-pig or human being, and it makes itself apparent as an inflammation of delayed onset which reaches its peak about two days after injection. Reactions which are later to develop into strong reactions are already discernible as soon as 15 h after injection, and for this reason some immunologists have been hesitant to accept our interpretation that the inflammatory process is the outward sign of an immunological reaction of the lymphocytes against their recipient, that is, of a primary 'graft-versus-host' reaction. Our original case for this interpretation rested (*a*) on its firm theoretical foundation, and (*b*) on the fact that the intensities of the reactions aroused by lymphocytes from a guinea-pig *R* in a panel of potential homograft donors D_1, D_2, D_3 . . . were almost exactly correlated with the intensities of the reactions provoked by grafting skin from D_1, D_2, D_3 . . . on *R*. This is just as it should be if the NLT reaction is an immunological response of the *R* lymphocytes to the 'transplantation antigens' of the *D* guinea-pigs. We now give further and, as we believe, conclusive evidence under two headings that this interpretation is in fact correct.

(1) Guinea-pigs which have received 500–1,500r. whole-body irradiation on a single occasion at the rate of 80r./min from a cobalt-60 source are fully capable of giving expression to an NLT reaction excited by blood lymphocytes or lymph-node cells injected from 2 h to 3 days later. The reactions begin at ordinary levels of intensity and remain so for three days; but where in a normal guinea-pig the reactions would now progressively fade, the inflammatory response in irradiated guinea-pigs rises between the third and the fourth day and continues to rise until, by the sixth or seventh day, the sites of injection have become transformed into huge purple lesions lying outside the ordinary range of scoring. Thus, when any possible immunological contribution of the host is reduced or abolished by irradiation, the NLT reaction, so far from being weakened, is intensified and prolonged.

(2) By making use of two unrelated inbred strains of guinea-pigs—Wright Strain 13 and the Heston Strain, itself remotely derived from Wright Strain 2—we have been able to put into practice the now classical experimental design in which lymphocytes from members of the two inbred strains are injected into the first generation hybrids of a cross between them, and vice versa. If the lymphocytes are reacting against antigens in their recipients, then an NLT reaction will be aroused by parental cells in the hybrid but not by hybrid cells in the

Table 1. NORMAL LYMPHOCYTE TRANSFER REACTION

	Recipients			
Heston lymph node cells	Heston −, − −, −	Strain 13 + + +, + + ± + +, + +	Hybrid (*Hes* × 13) + +, + + + ±, + +	Hartley + + + ±, + + + + + + ±, + + + ±
Strain 13 lymph node cells	+ +, + + ± + +, + + ±	−, − −, −	+ + ±, + + + + ±, + ±	+ + +, + + ± + + +, + + +
(*Hes* × 13) lymph node cells	−, − −, −	−, − −, −	−, − −, −	+ ±, + + ±, +

Readings 48 h after the intradermal injection into normal adult Heston, Strain 13, hybrid (*Hes* × 13) and Hartley guinea-pigs of 10 million mesenteric lymph node cells from normal adult Heston, Strain 13, and hybrid (*Hes* × 13) guinea-pigs: showing that the 'graft-versus-host' component is the only outwardly discernible component of the NLT reaction at this stage.

parent. If on the other hand the NLT reaction is the consequence of the host's response to antigens carried by the lymphocytes, then the exact converse should obtain. These possibilities were tested by the intradermal injection of 10 million mesenteric lymph node cells, or 5 million blood lymphocytes, in the combinations set out in Table 1. (Lymph node cells were preferable because our yields of blood lymphocytes from Heston and Strain 13 donors were relatively low, and contamination by red cells therefore relatively high. Normally red cells create no problem, but in situations in which the lymphocytes arouse no inflammatory reaction the red cells are not removed, and the brown stain they leave at the injection site can be a source of confusion.) The results that can be read from Table 1 are fully representative: (1) lymphocytes of the same genotype as their recipients arouse no reaction; (2) Heston and Strain 13 lymphocytes excite reactions in F_1 (*Hes* × 13) hybrids; (3) F_1 (*Hes* × 13) lymphocytes arouse no reactions in Heston or Strain 13 guinea-pigs; (4) lymphocytes from F_1 hybrids give rise to smaller reactions in Hartley guinea-pigs than do lymphocytes of either of the parental strains: this must be so if the 'graft-versus-host' interpretation is the correct one. It may be added that parental lymphocytes excite strong and progressive reactions in irradiated (800r) F_1 hybrids, so eliminating the very remote possibility that the NLT reaction in this genetic context owes anything to a response of the hybrid host to powerful recessive antigens in the parental cells.

These further lines of evidence uphold the belief that the 'graft-versus-host' reaction is the only immunological component of the NLT reaction that is outwardly discernible in the first three days. It is this property which justifies the use of the NLT reaction in the selection of donors for tissue transplantation[1,2].

Reagin-like Antibodies in Animals Immune to Helminth Parasites

RECENT investigations here have shown that rats, monkeys and sheep infected with helminth parasites produce an antibody with many of the properties of human reagin. Naturally occurring persistent antibodies of this type have not been demonstrated previously in animals, although in rats an antibody similar in its biological properties but transitory in appearance can be stimulated when antigen is injected with *Haemophilus pertussis* killed organisms as adjuvant[1,2]. Like human reagins[3], the antibodies stimulated by helminth infections become rapidly and apparently permanently attached to the skin of animals of the species in which they are stimulated, but they are incapable of sensitizing guinea-pig skin in passive cutaneous anaphylaxis.

Rats infected with their natural nematode parasite *Nippostrongylus brasiliensis* have been used as a model system in these experiments, and results obtained from this system applied to rats and monkeys infected with *Schistosoma mansoni* and to sheep infected with *Trichostrongylus colubriformis*. Reaginic antibodies are detected by utilizing their high affinity for cells in passive cutaneous anaphylaxis[4,5] with a 3-day interval between intradermal injection of antibody and intravenous injection of antigen. Serum from an infected animal is injected into the skin of a normal, worm-free animal of the same species as the animal donating the serum. Three days later, a mixture of antigen and Evans blue is injected intravenously. Within 20–30 min a discrete blue area, approximately 1·5 cm in diameter (but greater with strong reaginic antisera), appears at the site of injection of a serum containing the skin-sensitizing, reaginic antibodies. This test is the same in principle as the Prausnitz–Küstner test, which so far is the only reliable method available for measuring human reagins[3]. The reagin-like antibody titre of serum from helminth-infected animals is measured by serial dilution of the serum before intradermal injection. The test is positive for 7–10 days after intradermal injection of the antibody in rats, the maximum reaction being reached after 3 days. In this way, reaginic antibodies are distinguished from other antibodies which do not have an affinity for cells and which diffuse rapidly away from the site of injection[5]. With *N. brasiliensis* the best source of antigen for this passive cutaneous anaphylaxis is adult worms, although infective larvæ contain a lesser amount. Living adult worms collected from donors are broken up in a hand tissue grinder in phosphate buffered saline and the supernatant is used in the passive cutaneous anaphylaxis test, either fresh or after storage at −20° C.

In rats infected with *Nippostrongylus brasiliensis* (which becomes mature in the small intestine), reaginic antibody can be detected in the serum generally from day 25 after an initial infection and sometimes as early as day 19. In this species the production of reagin-like antibody is associated with sensitivity to anaphylactic shock[1,2]; and rats infected with *N. brasiliensis* can be shocked from the time that immunity first appears, that is, from the time egg counts fall at the end of an initial infection. As the gut is the 'shock organ' in rats[6], this behaviour suggests that the reaginic antibody is present on cells of the gut from the time the rat becomes immune. Unlike the transitory *H. pertussis*-induced reagin, the helminth-induced reaginic antibody in rats persists in the circulation for at least 7 months after a single infection, even in the absence of subsequent infections. Within 3 days of second and later infections, the antibody titre rises to high levels (1/200 to 1/1,600), remains high for a short period and then falls to a low level until a further infection.

Attempts to induce the reaginic antibody artificially by vaccinating rats with freshly homogenized adult worms or with the supernatant fraction only, with or without Freund's complete adjuvant, have been unsuccessful. No immunity to re-infection is stimulated by this method of vaccination, although precipitating antibodies (similar to those found occasionally in serum from multiply infected, highly immune rats[7]) are stimulated by it. On the other hand, the serum from vaccinated animals contains an

antibody which will inhibit the passive cutaneous anaphylaxis reaction if the antigen used in the reaction is incubated with the serum prior to injection; this blocking antibody may correspond to that found in the serum of allergic human patients after desensitization by injection of massive amounts of allergen[8]. The reaginic antibody found in serum from immune rats appears to be stimulated only by a living infection. A single normal infection of *N. brasiliensis*, a single infection with adult worms transferred into the duodenum, or 3 infections of larvæ irradiated to prevent development beyond the lung stage, will stimulate both immunity to re-infection and the production of the reagin-like antibody.

The antibody is stable at −20° C for at least 2 years, but it is destroyed by heating for 1 h at 56° C. Serum heated until reaginic activity disappears can no longer transfer immunity to re-infection passively. However, this does not provide definite proof of the role of reaginic antibody in immunity to infection with this parasite, as precipitating antibody from rats vaccinated with extracts of *N. brasiliensis* is also affected by such treatment so that it no longer precipitates in agar gel. This finding differs from previous work which indicated that hæmagglutinating rat antibody was unaffected by heat treatment[1].

In collaboration with Dr. S. R. Smithers, infections of *S. mansoni* have also been found to stimulate the production of reaginic antibodies in monkeys and rats. As with *N. brasiliensis*, the appearance of the antibody is correlated with the development of immunity to re-infection. Furthermore, when normal animals are infected by penetration of cercariæ through a skin area, saturated 3 days previously with reagin-containing serum, many cercariæ fail to develop to the adult stage.

There are many phenomena associated with helminth infections which may be explained by the presence of antibodies of the type described here, such as the self-cure reaction in sheep, immediate skin reactions in man, mast cell disruption and perh ps eosinophilia. Reagins cause disruption of mast cells when they react with homologous antigen[1,2]. Eosinophilia is closely associated with mast cell disruption, and is a characteristic feature both of helminth infections and of allergic reactions in man[10]. In mice infected with *Trichinella spiralis* degranulation of mast cells occurs when homologous antigen is injected[11], suggesting the presence of reaginic antibodies in *Trichinella* infections. Immediate skin reactions to worm extracts are used in diagnostic tests for helminth infections in man[9] and probably depend on the presence of reagins. It has been suggested that the self-cure reaction which is a characteristic feature of *Haemonchus contortus* infections in sheep may be explained by the presence of reagins[12]. Preliminary experiments jointly with Dr. D. L. H. Robinson have demonstrated an antibody with a high affinity for skin cells in sheep infected with *T. colubriformis*; but in this case the relationship between immunity to re-infection and the presence of this antibody is not yet clear.

So far, we have been able to stimulate reagins only by living infections, not by vaccinating animals with extracts of parasites. Nevertheless, these parasite extracts contain antigens which will react with reagins in passive cutaneous anaphylaxis. Stimulation of reagins must depend, therefore, on factors yet to be determined such as the route or rate of administration of the antigen, its physical or chemical state, and the ratio between the protective antigen and other components of the extracts used as antigen. We have shown that there is a close relationship between immunity to infection and the presence of reagins with the nematode *N. brasiliensis* and the trematode *S. mansoni*; it may well be that reagin-like antibodies are responsible for immunity to helminths in many species of animals. If reagins are necessary for immunity to re-infection, the problem of producing a vaccine for helminth parasites may be two-fold, first detection and production of the antigens responsible for protection, and secondly, injection of this antigen so that the protective antibody is stimulated.

BIOLOGY

Effect of Damage and Fungal Infection on the Production of Ethylene by Carnations

Although it has been well established that ethylene is produced in floral metabolism it is only recently that precise measurements have been made[1]. The rate of production by cut flowers is sufficient under conditions of limited ventilation to raise the concentration to levels which can have harmful effects. We have observed concentrations as high as 0·06 p.p.m. in cardboard boxes close-packed in the hold of the R.M.S. *Scillonian* carrying daffodils from the Isles of Scilly to the mainland. Concentrations of this order have been shown in this laboratory to reduce the life of the flowers if they are subjected to them for a period of several hours at room temperature.

The extent to which mechanical damage during packing and transport contributes to this production of ethylene is not known. Several workers have shown that damage to plant tissues is instrumental in raising the rate of production of ethylene, and that fungal attack will stimulate ethylene production[2–5].

During a series of experiments in which the rate of production of ethylene by carnations was being determined by gas chromatography, using equipment described pre-

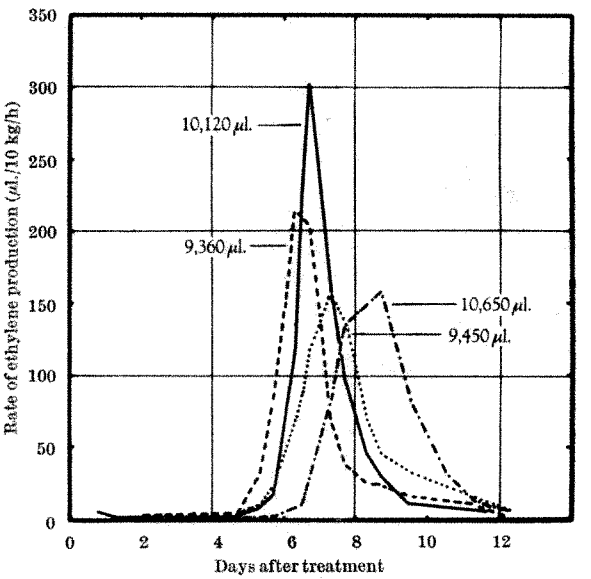

Fig. 1. Rates of production of ethylene from samples of 6 cut carnation flowers receiving treatments: untreated (·——·); inoculated only (.....); damaged only (—); damaged and inoculated (- - - -). Total volume of ethylene produced during the experiment from each sample is indicated

viously[6], a marked surge of ethylene production was observed with the onset of fungal attack. Further experiment gave comparison between the courses of production from undamaged flowers, flowers undamaged but inoculated with spores of *Botrytis* sp., flowers damaged by pricking the petals with a needle and flowers damaged and then inoculated. This showed that damage itself did not at once lead to a rise in ethylene production, that inoculation brought about an earlier rise in rate, while inoculation after damage resulted in the earliest rise in rate. The amounts of ethylene produced during the experiment by the samples were similar.

It seems likely that the ethylene is produced in the process of breakdown of the host tissues, since during growth of *Botrytis* sp. from carnation flowers on malt agar culture, no production of ethylene was observed.

These observations are of some practical significance. It is not unknown for flowers infected with fungal organisms to start to decay in transit. The magnitudes of ethylene production observed in these experiments suggest that if packages of infected blooms are included in a close-packed consignment they could constitute a hazard to the remainder.

Reversal by Histidine of the Inhibition of *Prototheca* Growth due to 3-Amino-1,2,4-triazole

3-Amino-1,2,4-triazole (amitrole) is used as a systemic herbicide. It also inhibits the growth of a number of micro-organisms including several algae. Organic acids have long been known to inhibit the growth of algae by combining with iron[1]. Aaronson[2] concluded that amitrole was also working in this way as the inhibition of *Ochromonas danica* could be abolished by the supply of extra iron to cultures in the presence of the inhibitor. Later Wolf[3], examining *Chlorella pyrenoidosa*, and Boney[4] certain marine red algae, reported that the inhibition by amitrole could be reversed by adenine. In this the algae are similar to *Escherichia coli*[5]. Histidine is effective in releasing the inhibition of *Torula cremoris*[5] and of *Saccharomyces cerevisiae*[6]. Since the standard medium used by Aaronson contained histidine[7], an investigation of the reversal of amitrole toxicity towards *Prototheca zopfii* was carried out. This colourless alga is believed to be closely related to *Chlorella* and it will grow in a mineral medium supplemented with glucose and thiamine[8]. Aaronson and Scher[7] showed that there was no significant difference in the concentration of amitrole required to achieve inhibition of *Euglena* and *Ochromonas* growth in the presence of an organic substrate in the dark as compared with the light although chlorophyll synthesis was inhibited.

Pure cultures of *Prototheca zopfii* (Cambridge Collection No. 263/5) were grown in 100-ml. Erlenmeyer flasks containing 20 ml. of a mineral salts medium[9] with the addition of 1 per cent glucose and 10^{-5} M thiamine. Additions of amitrole, and of other substances being tested, were usually made prior to the autoclaving of the medium (10 lb. for 15 min). After the flasks had been inoculated under aseptic conditions they were shaken in darkness at 25° C. After 2 or 3 days the dry weight of each culture was determined by use of sintered glass filter crucibles. Amitrole was obtained from L. Light and Co., Ltd. Other chemicals were obtained from B.D.H., Ltd., and were of analytical reagent quality where possible.

Initial experiments suggested that the concentration of amitrole giving 50 per cent inhibition of growth after 2 days was in the region of 8 mg per cent. Control cultures reached their final dry weight in 2 days. If inhibited cultures were left for a further day the concentration of amitrole corresponding to 50 per cent inhibition of growth was increased to some 15 mg per cent. A similar effect was described by Hilton[6] in relation to the inhibition of yeast growth by amitrole.

The ability of histidine to reverse the inhibition of the growth of *Prototheca* during a period of 2 days is shown by the results of an experiment in which the amitrole concentration was 15 mg per cent (Table 1). Riboflavin supplied in a similar experiment was without effect. Castelfranco *et al.*[10] have recently reported that riboflavin is effective in overcoming the chlorosis of higher plants, shown in the presence of amitrole, because the amitrole is decomposed in the presence of riboflavin and light.

Table 1. Effect of Various Concentrations of Histidine and Riboflavin on the Growth of *Prototheca zopfii* in the Presence and Absence of 15 mg per cent Amitrole

Conc. of histidine or riboflavin	Dry wt. (mg) Histidine		Riboflavin	
	− Amitrole	+ Amitrole	− Amitrole	+ Amitrole
0	101	13	103	8
5 mg %	104	101	101	10
10 mg %	103	102	100	10
15 mg %	100	104	101	8
25 mg %	101	102	101	10
50 mg %	100	99	101	11

Each flask contained 20 ml. of mineral medium with the other additions indicated. After inoculation the flasks were shaken in the dark at 25° C for two days when the dry weight of *Prototheca* in each flask was determined. The dry weight of the inoculum was 1·5 mg.

In the medium used iron is supplied as $FeSO_4.7H_2O$ in the presence of sodium citrate. Increasing the amounts of these salts supplied in proportion to the standard medium concentrations did not alter the amount of growth in control flasks or the degree of amitrole inhibition even at ten times the normal concentration of iron. Supply of adenine did not reverse the inhibition although it was reported to be effective in reversing the inhibition of *Chlorella pyrenoidosa*[3] (Table 2). In the case of *Chlorella* the concentration of amitrole required for 50 per cent inhibition was only 0·5 mg per cent, and the adenine concentration completely reversing this was of the order of 1 mg per cent, during autotrophic growth over 3–4 days. Adenine sterilized by Seitz filtration was equally ineffective in the case of *Prototheca*.

Table 2. Effect of Adenine on the Growth of *Prototheca zopfii* in the Presence and Absence of 15 mg per cent Amitrole

Adenine concentration	Dry wt. (mg) − Amitrole 2 days	+ Amitrole 2 days	+ Amitrole 3 days
0	101	17	62
5 mg %	100	14	45
10 mg %	99	13	52
15 mg %	99	14	48
25 mg %	102	13	40

Conditions of experiment as given in Table 1. Inoculum was 1 mg dry wt.

The results show that histidine will release the inhibition of growth by amitrole in the case of at least one alga and are in agreement with the conclusion of Hilton *et al.*[11] that reductions of amitrole toxicity by purines are usually small in comparison with those of histidine. Weyter and Broquist[5] found that histidine would release the inhibition of *Torula cremoris*, for which adenine was ineffective, but not that of *E. coli* unless adenine was also supplied when the reversal of inhibition was more complete than in the presence of adenine alone. Interactions between histidine and purines are also known from nutritional[12] and genetical[13] investigations suggesting that the site, or sites, of action of amitrole in metabolism may soon be detected. Klopotowski and Hulanicka favour inhibition of histidine biosynthesis[14], probably at the level of imidazoleglycerolphosphate dehydrase, as imidazoleglycerolphosphate accumulated in *Saccharomyces cerevisiae* in the presence of amitrole.

This explanation could apply in all cases where inhibition is overcome by histidine alone including *Prototheca* and several yeasts[5,6]. Castelfranco and Brown[15] suggest that the inhibition involves one electron oxidation of the amitrole.

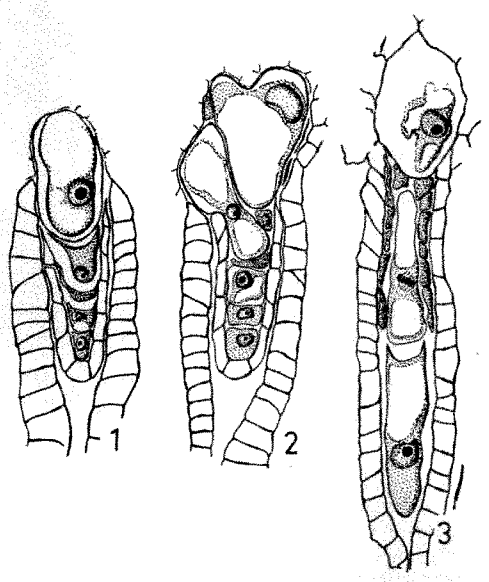
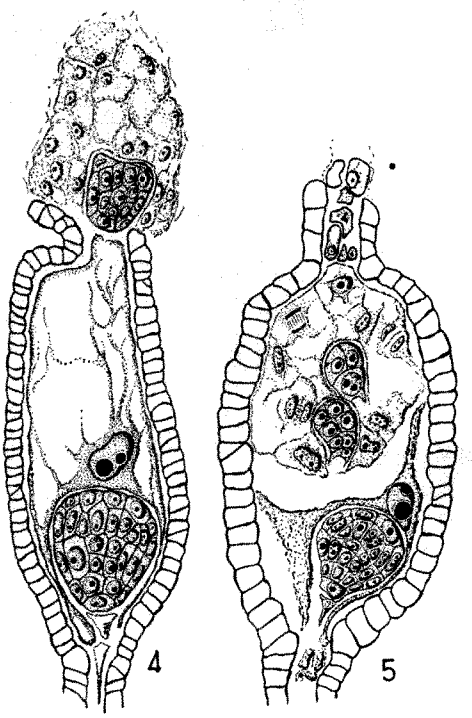
Somatic Apospory and Polyembryony in *Minuria integerrima* (DC) Benth



The genus *Minuria* (DC) is endemic to Australia and its six species are small undershrubs of the drier parts of the continent.

Material of *M. integerrima* (DC), Compositae, Astereae was examined from western New South Wales (Bourke, Condobolin, Brewarrina) and western Queensland (Dalby), all plants of which proved to be obligate apomicts with frequent polyembryony.



The single hypodermal archesporial cell functions directly as the megaspore mother cell and meiosis results in the formation of an apparently normal linear tetrad of megaspores which is enclosed by the nucellar epidermis.

During megasporogenesis, however, 1–3 chalazal nucellus cells develop large vacuoles and the closest one enters the nucellar lobe where it crushes, and finally replaces, the megaspores (Figs. 1 and 2). Breakdown of the nucellar epidermis then releases this aposporic cell into the micropylar chamber and after three successive nuclear divisions it becomes an 8-nucleate unreduced embryo sac of normal constitution. Fig. 3 shows two such aposporic cells developing within the endothelium, and a third one in the chalaza.

Multicellular apospory of this type has been reported in *Hieracium*[1], *Artemisia*[2] and *Crepis*[3], and in *M. integerrima* it is the basis of polyembryony, since each aposporic embryo sac commonly gives rise to an embryo by parthenogenetic development of the unreduced egg. A similar conclusion was reached by Rosenberg[4] in connexion with polyembryony in *Hieracium* subj. *Pilosella*.

Figs. 1–3. (Figs. 1 and 2, × 500; Fig. 3, × 400)

Figs. 4 and 5. (Fig. 4, × 150; Fig. 5, × 250)

In *M. integerrima*, when a single embryo sac develops, the polar nuclei unite to form the secondary nucleus which almost immediately divides into the first two endosperm nuclei. However, in every instance in which polyembryony occurred, the secondary nucleus of the micropylar embryo sac did not divide and consequently no endosperm was formed, although its embryo developed normally (Figs. 4, 5).

I thank Prof. N. C. W. Beadle, University of New England, and Mr. C. K. Ingram, Bathurst, for collecting the material on which this investigation was based.

A Staining Technique for the Examination of Nematode-trapping Fungi

Janus green, a bluish green basic dye of the mono-azo group, was observed to react in an interesting and useful manner with both nematode-trapping fungi and their prey. The dye is used at a concentration of 0·01 per cent in 0·2 M sodium acetate–acetic acid buffer at *p*H 4·6, and added drop by drop to the test material. Excellent results were obtained when the staining solution was applied directly to surface cultures of *Arthrobotrys conoides*, *A. dactyloides* and *Dactylella ellipsospora*, on maize-meal extract agar and on 'Cellophane'[1]. These fungi capture nematodes by means of adhesive hyphal loops, constricting rings, and adhesive knobs, respectively. The nematode used was *Panagrellus redivivus*.

Fungal walls and particulates (mitochondria and nuclei ?) stain dark green to blue. Organelles of capture that trap nematodes by adhesion stain most intensively, suggesting that the mucilage with which they are coated is acidic. Nematodes, captured and killed as a result of fungal activity, were bright yellow in colour. This is of particular interest since heat-killed worms stain dark green and living worms do not stain at all. The latter, when immersed for 24 h in a solution of Janus green, remain active and penetration by the dye is limited to the mouth region.

Janus green can be reduced biologically to a leuco base[2]. It is possible that partial reduction of the dye occurs in fungus-infested nematode tissue, and that the product of this transformation imparts to the preparation a bright yellow colour. Further speculation regarding the biochemical basis of the difference in colour produced when heat-killed and fungus-killed nematodes are stained with Janus green is not justified at this time. It is necessary only to emphasize that in treated cultures the dark-green fungal filaments and organelles of capture contrast dramatically with bright-yellow nematode carcasses. Contrast is augmented by lactophenol, and addition of this solution serves also to reveal hyphæ located within dead worms. Janus green facilitates greatly the investigation of nematode-trapping fungi as they develop in pure culture or from a soil inoculum. It appears to be a useful adjunct to the agar-disk method described by Cooke[3] for the direct observation of nematode-trapping fungi in soil.

This work was supported in part by U.S. National Science Foundation research grants *G*9749, *G*15950 and *GB*548.

Mechanism of Erection and Ejaculation in the Bull and Ram

It is generally considered that erection of the penis is produced by a combination of raised arterial pressure, restricted venous return, and relaxation of the walls of the cavernous spaces. In the bull and the ram, the process is extremely rapid, both in erection and relaxation, suggesting that a more positive mechanism exists.

A detailed investigation of this type of penis has been carried out using latex corrosion casts, gross dissection, and histological methods. The findings indicate a very different mechanism from that at present accepted, and certain anatomical similarities suggest that, in principle, it may apply to other mammals, including man.

The most significant feature of the two ruminant species investigated concerns the crura of the corpus cavernosum penis. These have become bulbous structures, situated between the ischial bones and the ischio-cavernosus muscles, so that contraction of the latter compresses the crura, forcing blood into the corpus cavernosum penis. This pumping action in the dog was noted by Henderson and Roepke[1]; but these authors were looking for a more obvious effect from the skeletal musculature and consequently attached little significance to the phenomenon.

The crura are covered externally by tunica albuginea, while internally there are large and small cavernous spaces. The larger ones receive blood from the deep artery of the penis (a. profunda penis), which is then passed to a large thick-walled vessel, which commences at the distal extremity of the crus. This joins the similar vessel from the other side and then, as a single vessel, traverses the dorsal part of the corpus cavernosum to the region of the sigmoid flexure, where it enters two large vessels situated at either side of the sulcus urethræ. These have their origin from the cavernous spaces at each end of the corpus cavernosum and their greatest diameter at the level of the flexure. They are intrinsic vessels of the corpus and their only connexion is to the dorsal vessel. The latter is generally described in anatomical texts as the continuation of the deep artery, while the ventral vessels are referred to as venæ profundæ. This nomenclature is obviously inapplicable in this case. From the ventral vessels arise side branches, which like the parent vessels have thick walls composed of elastic and smooth-muscle elements. The cavernous spaces are continuations of the side branches. Deysach[2] called them 'sluice channels' and postulated that they had a valvular action. The work recorded here does not support this finding, however, and probably the structure of the walls is concerned with maintaining a constant lumen under pressure. The cavernous spaces are lined by a single layer of endothelium and are surrounded by masses of fibro-elastic tissue which keep the spaces collapsed when the penis is quiescent. Pressure from the ventral vessels opens the spaces and compresses the fibro-elastic tissues, thus producing rigidity in the penis.

Increased pressure in the deep artery of the penis expands the larger spaces in the crura of the corpus cavernosum, causing them to swell. Under the stimulus of sexual excitement, the ischio-cavernosus muscles contract, compressing the crura and forcing blood into the vessels of the corpus cavernosum. Relaxation of the muscles allows blood from the deep artery to refill the spaces of the crura and this sequence is repeated until pressure in the corpus cavernosum equals that in the artery. Removal of the sexual stimulus stops this pumping action, and the retractor penis muscles actively pull the organ back into the prepuce thereby re-establishing the sigmoid flexure. This action displaces blood from the corpus cavernosum, which is passed back along the route by which it entered. Secondary drainage is carried out by relatively small veins which are connected to the smaller spaces of the crura.

In general this work has shown that the penis is adapted to attain erection with a minimum transfer of blood. The entire organ is enclosed in a thick, dense tunica albuginea which is virtually non-distensible, the corpus cavernosum is isolated except at the crura, and much of the internal volume has been reduced in terms of blood space by an increase in the amount of fibro-elastic tissue.

Forceful ejection from the urethral orifice is brought about by the bulbo-urethral muscle which encircles the bulbs of the urethra. The bulbs consist of large vascular spaces, filled by the artery of the bulb (a. bulbi urethræ). They are closed posteriorly but are continuous anteriorly with the sinuses surrounding the urethra. These commence around the pelvic urethra and have a continuous lumen to the glans penis where they connect with the deep dorsal vein. In the bull, the glans has very limited ability to distend. In the ram, however, there is a network of vessels in the galea glandis which is engorged by blood unable to escape by the deep dorsal vein. This is responsible for the enlargement of the glans in this penis. The vascular space of the tuberculum, situated behind the glans, is similar to that of the galea glandis in the method of engorgement.

The progressive contraction of the pelvic urethral muscle is continued by the bulbo-cavernosus muscle and forces blood from the spaces of the bulbs of the urethra into the sinuses. These, already distended and restricted by the corpus cavernosum penis and the tunica albuginea, are unable to expand externally, so that the pressure is transferred distally towards the glans, compressing the lumen of the urethra as it progresses. The contents of the latter are forced along the lumen ahead of this constriction and forcibly expelled at the external orifice.

Although veins have been described in relation to the bulbs of the urethra, they have not been observed in any of the specimens examined in this investigation. If they did exist their presence would detract from the efficiency of the system.

Observations on Sexual Attraction and Copulation in the Nematode *Panagrolaimus rigidus* (Schneider)

When observing cultures of *Panagrolaimus rigidus* to examine their life-history, copulation seemed to depend simply on chance encounters between males and females. However, as males often touched males without attempting copulation, there was the suggestion that different sexes attracted each other and those of the same sex repelled one another. Experiments were therefore made to see whether the nematodes produce sex attractants or repellents. The act of copulation was also observed in detail.

Fourth stage larvæ from cultures of *P. rigidus* on Nigon's nutrient agar[1] were placed singly in separate culture chambers to develop into adults. Troughs (Fig. 1) were made from lengths of clear polyvinyl chloride tubing of two sizes. Pieces of the narrower tubing, with a 'Cellophane' sheet placed over the end, were fitted into pieces of the wider tubing to make a firm joint between different sections of the trough, which were separated from each other by 'Cellophane' barriers. The two centre sections were marked off in centimetres from the central 'Cellophane' barrier. The sections were anchored to thin strips of 'Perspex' with adhesive tape. The troughs were filled with hot 1·5 per cent water agar so that good contact was made between bubble-free agar and the 'Cellophane' barriers. When the agar had cooled, 50 nematodes were introduced at the mid-points of each of the two centre sections and the two end sections left blank. To prevent drying out, the troughs were placed in closed tubes and left in the dark for 17 h at room temperature. They were then removed from the tubes, cut into cm lengths and the nematodes in each length counted.

When nematodes of the same sex were separated by a 'Cellophane' barrier, they were randomly distributed over each section, but when the different sexes were separated, they collected at the barrier (Fig. 2). Few nematodes remained between 1 and 2 cm from the barrier.

These results suggest that the sexes are brought together by water-soluble chemical attractants of molecular weight small enough to pass through a 'Cellophane' barrier and to diffuse up to 2 cm in 17 h. Because both males and females congregated at the barrier, and because there was no attraction between like sexes, both sexes must produce and be attracted by different specific substances. There was no evidence that like sexes were repelled.

No visible response to the chemical stimulus was seen when observing cultures of nematodes or when tracking isolated pairs. The tactile response of the male which led to copulation occurred only when its posterior third came into contact with the female. The responsive region in the male is therefore probably spread over this part in which the spicules are situated. When a male touched a female there was an immediate ventral coiling of the male's tail to form a loop into which the spicules projected. On some occasions the female was trapped in the loop and the male tail then remained coiled until the end of copulation or until the female had escaped. The female continued to move about and feed during this process, and, in doing so, moved forwards and backwards through the loop. Thus the spicules sometimes, but not invariably, came into contact with the vulva and penetrated the opening. The spicules were then firmly held and the male was dragged about by the movements of the female. At the end of copulation, the male gradually uncoiled, but the strong grip was only broken with considerable effort. Copulation lasted from 15 sec to more than 30 min. Where the female moved out of the loop before the vulva was penetrated, the male made no attempt to

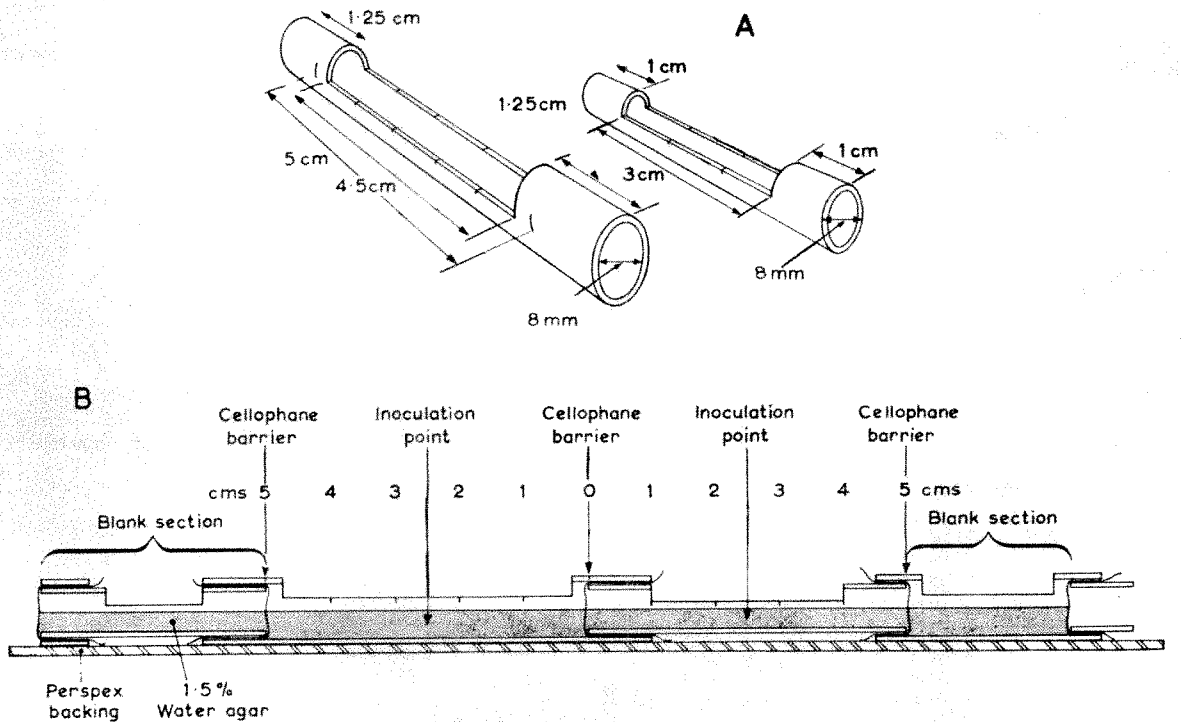

Fig. 1. A trough for testing for sex attractants. *A*, Sections cut from clear polyvinyl chloride tubing ('Tenatube'), with dimensions given; *B*, sectional view of assembled trough

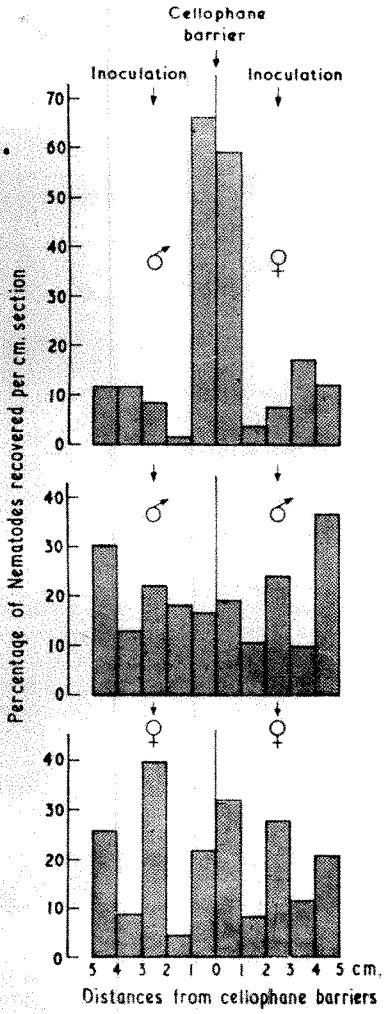

Fig. 2. Distribution of nematodes in troughs after 17 h at room temperature. The mid-line of each set of histograms represents the 'Cellophane' barrier between the two sections. Arrows indicate points of inoculation

re-engage unless their movements brought them into contact again. Copulation or attempted copulation by other males often occurred immediately after the female had been fertilized and females were often seen beset by several coiled males at the same time.

The attractant substances seem to serve only to bring the sexes together and their effects cannot normally be perceived in cultures. The act of copulation seems to be evoked only when the male tail makes contact with a female and so the apparently tactile stimulus may in fact contain an element of chemical stimulation which enables it to distinguish between male and female.

MICROBIOLOGY

Structure of a Chromatophore Fraction of *Rhodopseudomonas spheroides*

Cohen-Bazire and Kunisawa[1] have reported that the chromatophores of *Rhodospirillum rubrum* can be separated into two fractions by centrifugation in a sucrose density gradient. From their relative positions in the gradient, they were designated 'heavy' and 'light' chromatophores.

We wish to describe the preparation of analogous fractions from *Rhodopseudomonas spheroides* and some of their properties, including X-ray diffraction investigations of the light fraction.

R. spheroides, strain 'Ga', was grown in a synthetic medium[2] at a light intensity of 600 ft.-candles. The cells were gathered by centrifugation, washed and resuspended in TSM buffer (*tris*-hydroxymethyl aminomethane, 0·02 M; NaCl, 0·08 M; $MgSO_4$, 0·01 M; *p*H adjusted to 7·8 with HCl). The cells were disrupted in a French pressure cell. DNase was added to reduce the viscosity, and the extract was centrifuged at 20,000 *g* for 25 min; the pellet was discarded. A solution of 0·1 M *tris* buffer (*p*H 7·8) containing $MgSO_4$ and RbCl was added to the supernatant to bring the final concentration to 0·05 M $MgSO_4$ and 27 per cent (w/w) RbCl. This mixture was centrifuged in a Spinco preparative centrifuge at 75,000 *g* for 4·25 h. The chromatophore fraction floated to the top of the tube, and the ribosomes formed a pellet which was discarded. The chromatophore layer was removed, diluted with TSM and centrifuged at 75,000 *g* for 1·5 h, after which all the pigmented material had formed a pellet. This was resuspended in TSM and layered on top of a linear density gradient of sucrose (35–47 per cent sucrose in TSM); this was centrifuged in the *SW* 25·1 rotor at 23,000 r.p.m. for 7 h. Essentially all the chromatophore material was present in two bands, the upper one of which was at the position in the gradient corresponding to a density of 1·14 g/ml.; this is the light fraction. The material in each band was removed through a hole in the bottom of the tube, diluted with TSM and centrifuged at 100,000 *g* for 1 h.

The chemical compositions of the two fractions are quite different (Table 1); this corroborates the observations of Cohen-Bazire and Kunisawa. It is significant that the ratio of bacteriochlorophyll to neurosporene is higher in the light fraction than in the heavy. This suggests that the two fractions are not entirely artefacts. The light fraction is monodisperse in the analytical centrifuge and has a sedimentation coefficient of 153*S* (corrected to infinite dilution in water at 20° C). The heavy fraction is polydisperse.

Table 1. Chemical Composition of Light and Heavy Chromatophore Fractions from *R. spheroides*

Fraction	Component (per cent dry weight)		
	Protein	Bacterio-chlorophyll	Neurosporens
Light	59·9	8·40	1·62
Heavy	63·2	5·08	1·24

The remainder of the dry weight is largely carbohydrate and lipid.

After two successive sedimentations at 100,000 *g* for 1 h of the material from the density gradient, resuspending each time in TSM, a sample of the final pellet was sucked into a quartz capillary, sealed, and used as the X-ray diffraction specimen.

Most diffraction photographs were taken with a low-angle short-slit camera using nickel-filtered copper $K\alpha$-radiation of 1·54 Å wave-length and Ilford 'Industrial *G*' X-ray film. The specimen-to-film distance was 15 cm and spacings could be resolved to about 400 Å. Other pictures were obtained with a quartz crystal focusing monochromator, which could only resolve spacings to about 100 Å, but which gave clearer patterns at higher angles.

The 'heavy' fraction gave no observable discrete diffraction maxima.

The 'light' fraction, however, gave a number of discrete maxima as shown in Fig. 1. The positions of these maxima can be interpreted quite precisely as the diffraction from a hollow sphere of mean shell radius 295 Å (see Table 2), and calculations show that the wall thickness could not be greater than about 100 Å. The best fit to the observed data is achieved with a uniform shell thickness of 60–80 Å. The data cannot be fitted to the diffraction predicted for a solid sphere.

Table 2. Analysis of X-ray Intensity Maxima from Light Chromatophore Fraction of *R. spheroides*

Peak	a	d (observed) (Å)	r (= ad) (Å)
1	0·715	?*	—
2	1·229	240	295
3	1·735	170	295
4	2·239	131	294

Five and beyond, unobserved; predicted to be very weak.
The equivalent radius r is calculated for a thin-walled hollow sphere from the equation $r = ad$ where a is a known constant and is tabulated in the second column above.
* Peak 1 should occur at $d = 412$ Å; present apparatus can just detect this peak, but it cannot be measured accurately.

There is also a diffuse reflexion in the neighbourhood of 50 Å (Fig. 2), suggesting a dominant spacing of this order in the structure. Calculations indicate that the intensity given by a uniform hollow sphere in this region would be much less than that observed, thus suggesting the presence of substructure of this order of size. Two explanations suggest themselves: First, if the shell were composed of a unit membrane, a diffuse reflexion might appear in this region, corresponding to the double lamellar structure. Secondly, since the chromatophore has a shell structure, the shell is very likely to be built up of sub-units in regular or quasi-regular array as are the spherical viruses[3], and the 50 Å reflexion could be a diffraction maximum corresponding to the distance between sub-units,

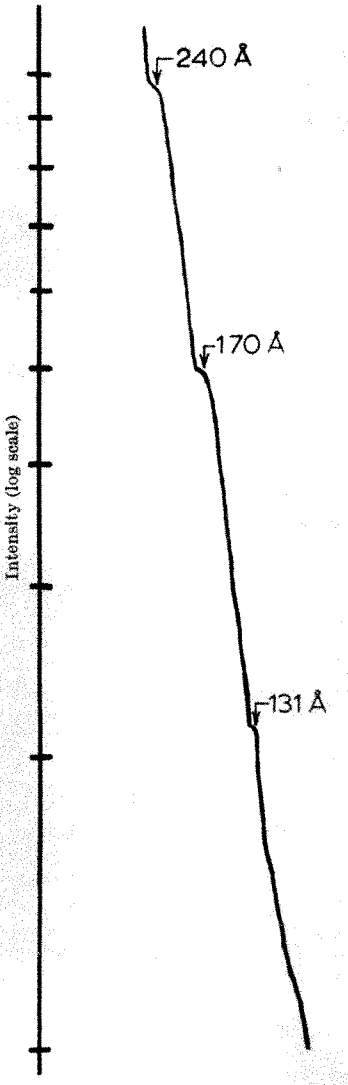

Fig. 1. The X-ray intensity distribution scattered by *R. spheroides* chromatophores (light fraction). This figure has been redrawn on an arbitrary logarithmic intensity scale from the original linear densitometer traces

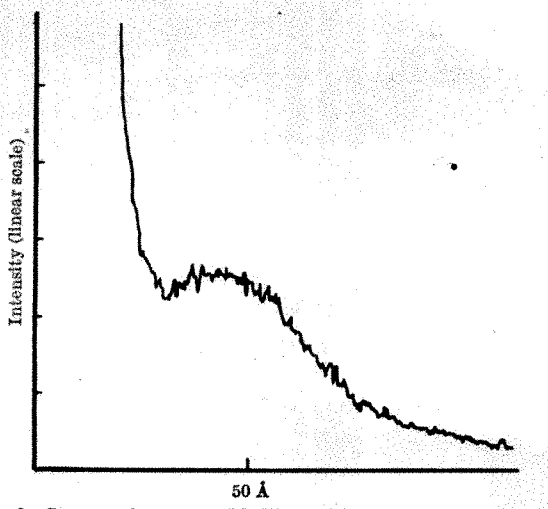

Fig. 2. Same specimen as used in Fig. 1, but wider angle data obtained with a different camera. Copied directly from the densitometer trace on an arbitrary linear intensity scale

or to the distance between holes in the shell (that is, the spaces between groups of sub-units, as observed in turnip yellow mosaic virus[4]). Since other chromatophores may have a shell structure (for example, *Chromatium*[5]), it is probable that similar construction principles apply. There is evidence for protein sub-units only in the case of *Chromatium*[5].

It may further be suggested that since the chromatophores of *R. rubrum* appear to be formed from the cytoplasmic membrane[6], then the membrane has a similar substructure. It is also likely that the structure of the lamellar photosynthetic apparatus of *R. molischianum* (which is also developed from the cytoplasmic membrane[7]) is based on similar principles.

It should be emphasized that these results on extracted chromatophore fractions do not necessarily indicate the intracellular structure of the photosynthetic apparatus. However, we feel that the structure and remarkable homogeneity of the light fraction are manifestations, under the conditions of isolation, of the high degree of order undoubtedly possessed by the photosynthetic apparatus within the cell.

CYTOLOGY

Chromosomes of the Domestic Cat

THE recent advances in the visualization of diploid metaphase chromosomes of mammalian somatic cells have offered new opportunities to verify and extend previous techniques in which mitotic rates, DNA measurements, and various tracer techniques have been used to analyse cellular kinetics. Investigations of these latter types have been reported on human and dog bone marrow cells[1–3]. Some limited studies on replication of human chromosomes, particularly the sex chromosome, have also been reported[4].

The usefulness of chromosome studies for replication kinetics depends on the definite and reliable identification of chromosome pairs, or of small groups of similar chromosomes. Brief examination of the karyotype of the dog[5] suffices to show the inadequacy of this species in this respect. The human karyotype is superior to that of the dog, but it still leaves a great deal to be desired. Experimental limitations also demand an alternative species.

The cellular morphology of the bone marrow of the domestic cat is very similar to that of dog and man. The chromosomes are sufficiently varied to promise a reasonable degree of accuracy in reliably identifying a number of pairs (Fig. 1). Few investigations of cat chromosomes are available in the modern literature and these are not in agreement[6,7]. We are, therefore, presenting a karyotype which we feel offers a workable arrangement, particularly for replication kinetic investigations.

Bone marrow was obtained by aspiration from anæsthetized male cats. Suitable sites are the distal end of the femur, the proximal end of the humerus, the ribs, and the iliac crest. The aspirate was dispersed in 20-ml. heparinized saline (sodium heparin 1 : 10,000). The suspension was centrifuged at 800 r.p.m. for 10 min, the supernatant was discarded, and the cells were resuspended in serum–glucose–saline medium[8]. The cells were incubated for 1 h at 37° C after the addition of 1·0 μg/ml. 'Colcemid' (Ciba). The cells were again centrifuged and resuspended in 5·0 ml. of 0·95 per cent sodium citrate. After 10 min incubation at 37° C the suspension was transferred to a 15-ml. conical centrifuge tube and centrifuged again for 10 min at 800 r.p.m. The supernatant was discarded and the cells were fixed by the slow addition of 5 ml. of cold acetic acid/alcohol (1 : 3). After a minimum of 30 min the fixation process was repeated.

After a minimum of 12 h fixation at 4° C, the cells were resuspended in fresh fixative and the cells dispersed and fixed on a slide by 'blazing'[9].

The slides were stained for 30 min in 2 per cent Giemsa stain at *p*H 7·0 and photographs were made of best-quality chromosome preparations.

The karyotype presented here follows the general recommendations of the Denver conference on human chromosome karyotype[10]. Autosome pairs are grouped by size and by centromere location. Pairs within groups are ordered in respect to decreasing size. Metacentric and near-metacentric pairs are situated at the left and sub-telocentric and telocentric pairs at the right. In our karyotype (Fig. 2) chromosomes are grouped when they cannot be distinguished reliably as individual pairs.

The largest pair, 1, is sub-metacentric. Its arm ratio measures approximately 2 : 3. The metacentric pair 2 and the sub-telocentric pair 3 are appreciably smaller. The arm ratio for 3 is 1 : 4.

The medium-large group 4-7-*X* are metacentric or nearly so. Individual autosome pairs cannot be reliably identified and the *X* chromosome is generally indistinguishable within this group.

Pairs 8–10 are sub-telocentric with an arm ratio of 1 : 3. They cannot be individually identified as a rule although we occasionally can find one pair with a greater degree of telocentricity. Under the general scheme this pair would be assigned position 10.

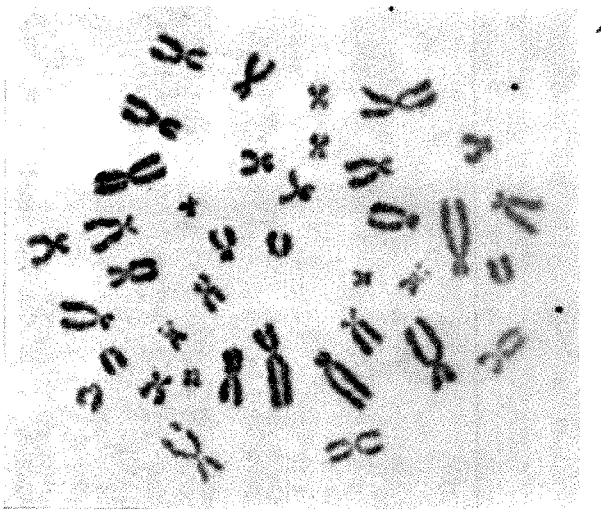

Fig. 1. Typical chromosome preparation from cat bone marrow

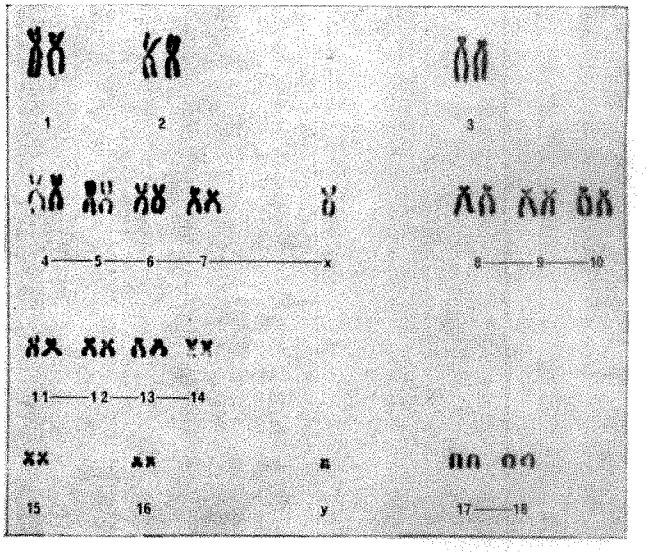

Fig. 2. Proposed karyotype for the domestic cat

The medium-small metacentric and nearly metacentric group 11–14 presents difficulties similar to those encountered in the 4–7 group. Pair 14 is distinguishable only when the satellites are well defined. We have observed this satellite phenomenon to be quite variable. Furthermore, it is common to find only 1 chromosome with a well-defined satellite.

The small pairs 15–18 present little difficulty. The metacentric pair 15 is larger than metacentric pair 16. Pairs 17 and 18 are easily identified as small telocentrics but are indistinguishable from one another.

The *Y* chromosome is the smallest metacentric and is sometimes confused with one of the autosomes of pair 16.

Of 203 chromosome preparations analysed by photographic methods, 186 contained 38 chromosomes. Three had 39, three had 40, and 11 had 34–37 chromosomes. A similar distribution of chromosome number has been reported for human bone marrow cells[11].

It should be mentioned that in all normal bone marrows which we have examined there is a constant small number (< 1 : 1,000) of polyploid metaphases. These may be megakaryocytic in origin, and our finding supports the observation of Garcia[12] that DNA contents of megakaryo-

cytic cells are often polyploid. Most of our polyploid metaphases are tetraploid (8 *n*), although there is a rare 16 *n*, and on one occasion a 32-*n* cell was seen.

Unusual Action of Heparin on Ascites Tumour Cells during Freezing and Thawing

THERE is very little experimental evidence concerning the site or mechanism of cellular injury during the cooling, freezing and rewarming of living cells. Membranes of erythrocytes[1] and of mitochondria[2] have been suggested as cellular regions which are injured during freezing and thawing by increased salt concentrations. During investigations of freeze-thaw induced structural alterations of Littré ascites tumour cells, I decided to use heparin to minimize the coagulation of cell suspensions which frequently occurred soon after these cells were gathered from host mice. This use of heparin resulted in a dramatic fading of nuclei when the ascites cells were subjected to freezing and thawing. The purpose of this brief communication is to describe this action of heparin and to propose a tentative explanation of the phenomenon which provides evidence that the cell membrane is a site of freeze-thaw injury.

Ascites cells were obtained from Webster white Swiss mice, 12 days after intraperitoneal injection and incubation of 20 million cells per animal. Heparin (sodium, with 0·9 per cent benzyl alcohol in water; Vitarine Co., Inc., New York) was mixed with a portion of each sample in the amount of 0·025 c.c./c.c. of cell suspension, the equivalent of 250 heparin units/c.c. The remaining part of the sample served in comparison as the non-heparinized cell suspension. Phase microscope observations on unfixed, unstained cell preparations were made before freezing and after thawing in the presence and absence of heparin. One c.c. portions of cell suspensions were frozen rapidly in liquid nitrogen to −196° C in sealed glass ampoules at an average rate of 5° C/sec and thawed slowly in air (22° C) at 4·5° C/min. 'Live-dead' staining with eosin was used as an indicator of altered membrane permeability with each treatment.

Hæmocytometer measurements of total cell counts following 12-day incubation in hosts after transplantation were made in split-sample comparisons of control and experimental conditions. An increase in population served as an indicator of viability of transplanted cells.

Results revealed that in unfrozen control samples heparin did not alter either the structure of cells or their ability to divide. When cells were frozen and thawed, however, a marked difference in structure was noted between those suspensions with and without heparin (Fig. 1). Aside from the usual nuclear and cytoplasmic alterations (flattening of cells, blebbing, chromosome clumping, etc.) which occurred during these rates of freezing and thawing (details to appear elsewhere), nuclei of non-heparinized frozen-thawed cells showed distinct chromatin or chromosomal and nucleolar structures. In all but a few (< 0·5 per cent) frozen-thawed heparinized cells, however, the nuclei became as clear as an empty vacuole, as if devoid of nuclear contents. Only after careful scrutiny were evidences seen of faded nucleoli and hints of chromatin networks. Chromosomes in mitotic stages were never observed in the hundreds of these preparations examined, although they were numerous in non-heparinized frozen-thawed samples. There was no evidence of mitotic activity of the cell populations in the 12-day incubation period subsequent to transplantation of either frozen-thawed heparinized or frozen-thawed non-heparinized cells. Heparin action, therefore, seemed to provide a good index of survival. Ascites fluid in frozen-thawed heparinized samples also showed a marked gelation.

It appears that the intact plasma membrane acted as a barrier to the penetration of heparin since heparin was not observed to affect unfrozen cells. When this membrane was injured during freeze-thawing, however, and its integrity diminished, heparin readily entered the cell and acted on the nucleus. All but a very few cells became permeable to eosin after freeze-thawing, thus supporting the interpretation of such membrane alteration[1]. In addition, when heparin was added to frozen-thawed non-heparinized cells, the same fading of nuclei occurred as with cells frozen with heparin.

The belief that an intact plasma membrane is the barrier to heparin penetration was strengthened by results of additional experiments. Heparin (250 units/c.c.) was added to fresh nuclei isolated from chicken erythrocytes suspended in isosmotic sucrose prepared by Dr. Henderson of the Department of Biochemistry. The suspension

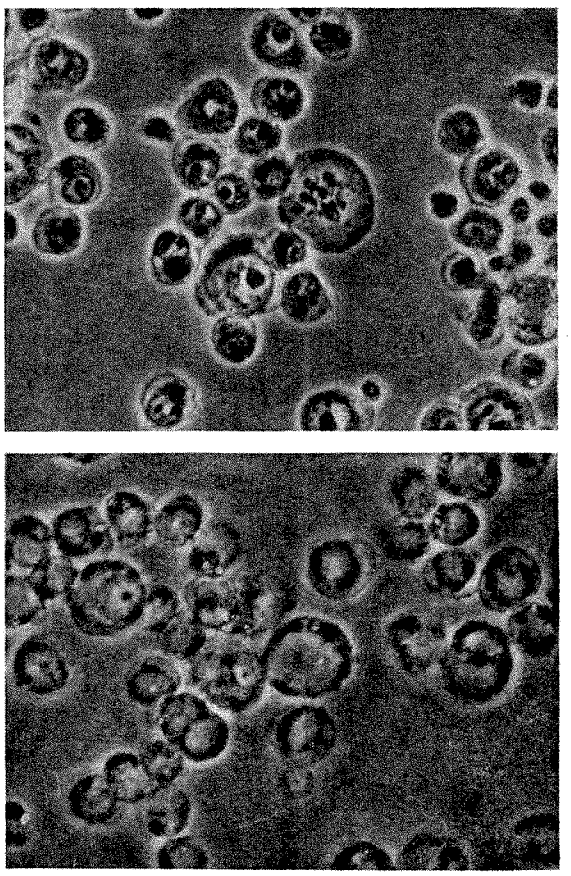

Fig. 1. Effect of heparin during freezing and thawing of ascites tumour cells. *a*, Untreated frozen-thawed cells; *b*, heparinized frozen-thawed cells. Note fading of nuclei. (Phase contrast, × *c.* 330)

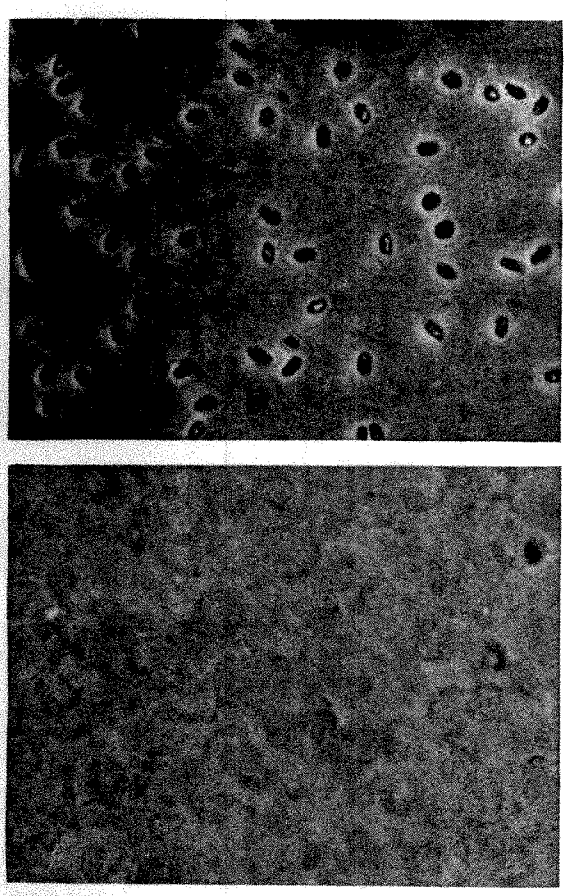

Fig. 2. Effect of heparin on isolated nuclei of chicken erythrocytes. *a*, Nuclei before addition of heparin; *b*, nuclei after addition of heparin. Note fading of nuclei and swelling of membranes. (Phase contrast, × *c.* 375)

immediately clarified macroscopically and became extremely viscous in the form of a continuous gel. Microscopically, the nuclei were observed to fade completely with their swollen membranes or ghosts representing the only nuclear structure visible (Fig. 2). Heparinized and non-heparinized chicken erythrocytes then were examined in the same manner as ascites cells. Heparin did not affect the structure of these nucleated cells before freezing. Subsequent to the hæmolysis induced during freezing and thawing with the coefficient membrane injury and the exposure of nuclei, however, heparin readily induce nuclear fading and increase the viscosity of the medium to almost the same extent as with preparations of isolated nuclei.

The increased gel-like viscosity of the medium which surrounded heparinized frozen-thawed preparations of chicken erythrocytes, or their nuclei, as well as ascites cells, was afterwards shown to be readily liquefied by the addition of DNase. It is strongly suggested, therefore, that nucleoprotein leaks from frozen-thawed ascites cells through the injured plasma membrane after the intracellular action of heparin. Preliminary experiments on sedimentation rate and ultra-violet absorption with nuclei of chicken erythrocytes were performed to evaluate possible heparin induced solubilization of nucleoproteins. Heparin was shown to cause, at the least, a dispersion of the usually insoluble nucleohistones in these nuclei. This and other aspects of chemical analyses are under investigation by Dr. Henderson and me.

Crystalline potassium heparin (250 units/c.c.) has been shown to duplicate effects described here, establishing heparin as the active agent in the Vitarine heparin solution. Closely related chondroitin sulphate *A* was found entirely without effect even in much higher concentrations. Results of parallel histochemical investigations on DNA and RNA have supported the concept of nucleoprotein dispersion. In addition, autoradiographic analyses with tritiated thymidine have given evidence for leakage of DNA from heparinized frozen-thawed ascites cells.

It is proposed that freezing and thawing at the rates described injure the plasma membrane of ascites cells, permitting the penetration of heparin which causes dispersion and leakage of nucleoprotein. A basis for a method of obtaining nucleoprotein from cells is suggested.

GENETICS

Production of Maternal-type Plants through Crosses to Apomictic Species

The process of apomixis normally involves two complementary deviations from sexual behaviour. A functional egg cell with unreduced chromosome number must first be produced, and, secondly, it must develop into an embryo without being fertilized. When the first of these stages follows the apomictic pattern and the second follows a sexual pattern, triploid progeny are produced. In the opposite case, the resulting progeny will have the haploid chromosome number.

When apomictic triploid *Rubus canadensis* L. was crossed with sexually breeding tetraploid blackberries, Craig[1] obtained both triploid and pentaploid seedlings. The triploid seedlings were normal apomicts, whereas the pentaploids arose through unreduced eggs being fertilized by diploid sperm cells. When the reciprocal cross was made, he found diploid, triploid, tetraploid and pentaploid seedlings. The diploid seedlings arose through reduced eggs developing without fertilization, whereas the other seedlings were produced through reduced eggs being fertilized with haploid, diploid, or triploid sperm cells.

In the hope that triploid *R. canadensis* pollen might similarly induce haploidy in the diploid red raspberry, four red raspberry varieties were pollinated with *R. canadensis* pollen in 1961. Except for one triploid plant, none of the 26 seedlings obtained from the four crosses showed any evidence of blackberry parentage. Cytological investigations showed them all to be diploid.

A similar result was obtained in crossing cultivated strawberries with an apomictic species. When the runnerless ever-bearing diploid variety 'Baron Solemacher' was pollinated with 'Sparkle' pollen, only apomictic seedlings were produced. However, when six cultivated octoploid strawberry clones were pollinated with 'Baron Solemacher' pollen, all 36 seedlings produced were maternal-type octoploids.

The exact mode of origin of the maternal-type plants has not yet been determined. Three possible modes can be postulated: (1) apomixis; (2) chromosome doubling of haploids; (3) contaminated crosses. While some contaminants could have been included in the maternal-type raspberry seedlings, this possibility was virtually eliminated with the strawberry crosses. Morphological variations between seedlings would tend to rule out apomixis in the raspberry crosses; but with the possibility of contaminants one cannot be sure of this. There is, in fact, no reason to conclude that all the seedlings even in a given progeny were produced by the same mode of action.

The breeding behaviour of the plants concerned is being further examined. The crosses are being repeated on a larger scale and the raspberry seedlings are being tested for homozygosity. However, the technique for the pro-

duction of maternal-type seedlings using pollen of apomictic species should be of considerable value regardless of its mode of action. If the process is by apomixis, then it should be useful as a means of eliminating non-seedborne viruses. If it is by chromosome doubling of haploids, then the technique will be extremely useful as a ready means of producing homozygous lines for breeding purposes.

$D_{Adelaide}$—a New Transferrin Variant in Man

Inherited variation of the serum protein transferrin was first detected in man by Smithies in 1957, using starch-gel electrophoresis[1]. At present 16 different human transferrin variants have been described. Fourteen of these are summarized by Parker and Bearn[2]. The fifteenth, B_{Lae}, was observed in a single pedigree in New Guinea[3], and the sixteenth, D_{Wigan}, has been reported recently in an English family[4].

Transferrin C is the commonest variant; it is found in all populations. Variants with an electrophoretic mobility faster than C have been given the notation B; slower variants, the notation D. Subscripts distinguish the different B and D variants.

The difference between C and any one of the variant types is probably determined by a single gene pair without dominance. In addition, the discovery by Beckman and Holmgren of a family in which B_2D_1, B_1D_1 and B_1B_2 individuals lacking a C band were found suggests that the genes for B_1, B_2 and D_1 are allelic[5]. Otherwise, little information is available concerning the relation between the genes which determine the different variants.

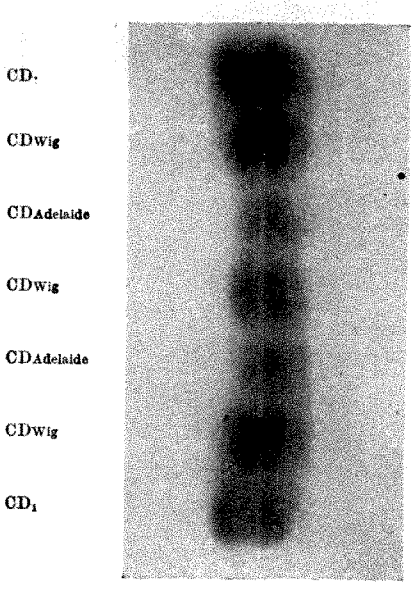

Fig. 1. Autoradiograph of a segment of starch gel comparing transferrin variants. Borate buffer *p*H 8·9, 7 V/cm for 16 h at 20° C

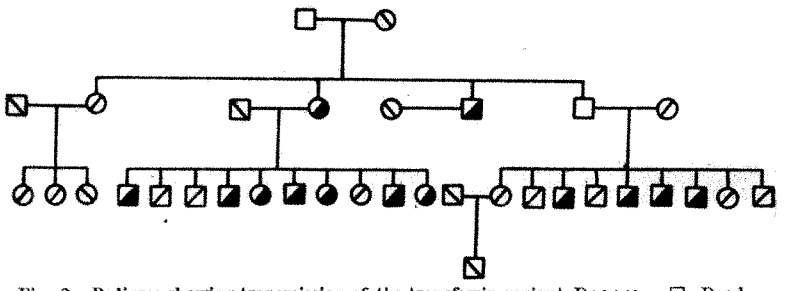

Fig. 2. Pedigree showing transmission of the transferrin variant $D_{Adelaide}$. □, Dead, not tested; ▣, alive, not tested; ◪, alive TFC; ◪, alive $CD_{Adelaide}$

We have recently found what would appear to be a new D variant in an Australian family of Irish–Italian origin. Fig. 1 shows an autoradiograph prepared after electrophoresis of serum from a member of this family alongside standard sera containing D_{Wigan} and D_1, using a vertical starch-gel system and a borate buffer at *p*H 8·9. ^{59}Fe-citrate was added to the serum to give an activity of 6 μc./ml. prior to electrophoresis.

Repeated tests have shown that the transferrin variant present in this family is faster than D_1, D_{Chi}, $D_{Montreal}$, D_{e-1} and D_{Wig}. Possibly it is identical with D_O, a variant first identified by Giblett *et al.* in an American Negro[6]. Unfortunately all supplies of the serum containing D_O have been exhausted, and the original donor is no longer available. For this reason no test of this possible identity can be carried out. However, the transferrin present in the Adelaide family is detectably faster than a transferrin found in the serum of a Thai from northern Thailand, provisionally identified as D_O by Kirk and Lai[7], in the absence of a comparison with standard D_O serum.

For the reasons cited here, we feel justified in establishing this transferrin as a new variant for which we propose the name $D_{Adelaide}$. It has the highest mobility of the known D variants for which serum is available for testing purposes.

The inheritance of $D_{Adelaide}$ is shown in the pedigree of Fig. 2. The hypothesis of a single gene pair without dominance is consistent with the data.

The pedigree was originally investigated because some members possessed a congenital non-spherocytic hæmolytic anæmia which was found to be associated with a deficiency of the enzyme, pyruvate kinase, in their red cells. This aspect will be considered elsewhere by one of us (H.L.) in association with others. There was, however, no evidence to suggest that the presence of this variant of transferrin was in any way connected with the possession of pyruvate kinase deficient erythrocytes in the family. Their loci appear to be independent.

The appearance of members of this family does not suggest an admixture of Australian Aboriginal blood, nor has the family been in Australia a sufficient number of generations for this to be undetectable had it occurred. It would appear, therefore, that the gene is European in origin. Its frequency, however, must be very low since it has not previously been detected in surveys of persons of European descent in various parts of the world, and in which serum from several thousand persons has been examined.

Part of this work was supported by a grant from the Nuffield Foundation to one of us (R.L.K.).

PSYCHOLOGY

Machine Learning from Noisy Information

A METHOD of approach is described here in connexion with international telegraph (Morse) code, but not much change is necessary with other systems of substitution ciphers[1]. At this stage no reference is made to a vocabulary or to the syntactic and semantic context[2].

Let us start with zero noise-level and come later to the simulation of noise.

As is known, there are five different basic elements in the Morse code: dot, dash, intra-letter space, inter-letter space, and inter-word space. (For the sake of simplicity, we will now ignore punctuation marks. Their inclusion does not, however, represent any difficulty.) By using single-letter frequency charts for English and establishing the word-length distribution function with regard to the number of letters in a word (an analysis of 4,000 words, for example, has given an average word-length of 4·49 letters), we can show that the respective frequencies of the foregoing basic elements are $f_1 = 0{\cdot}308$, $f_2 = 0{\cdot}198$, $f_3 = 0{\cdot}297$, $f_4 = 0{\cdot}155$ and $f_5 = 0{\cdot}045$.

A computer can easily pick out the three basic elements that represent spaces since two identical of these can never be found in sequence. (We may note here that considerable research has been done in the related field of computer recognition and transcription of manual Morse, such as by Blair[3], Freimer *et al.*[4] and Gold[5].) When the information becomes noisy, as set out later, the machine looks for the elements with minimum number of repetitions in sequence. A comparison between the frequencies of occurrence of the elements so selected allows completion of the further classification (intra-letter, inter-letter and inter-word) due to the significant differences between f_3, f_4 and f_5. In a similar fashion dots and dashes can also be distinguished.

The next step is to apply the well-known statistical procedure used to fit different basic frequency distributions to an empirical one. It is necessary to minimize :

$$\chi^2 = \sum_{(\alpha)} \frac{(f_s^{(\alpha)} - f_p^{(\alpha)})^2}{f_p^{(\alpha)}} \qquad (1)$$

where the summation is extended over the whole alphabet; $f_p^{(\alpha)}$ is the frequency of occurrence of a particular letter (α) in the established chart (population value); $f_s^{(\alpha)}$ is the sample value of the same quantity for the letter assumed to be the same. The minimization is carried out by systematically changing the equivalence table (representations) of the Morse code. The starting set is usually very near to the optimum but, of course, it need not necessarily be the true set. A more reliable, but much more complicated, procedure would be the minimization of :

$$\chi^2 = w_1 \sum_{(\alpha)} \frac{(f_s^{(\alpha)} - f_p^{(\alpha)})^2}{f_p^{(\alpha)}} + w_2 \sum_{(\alpha,\beta)} \frac{(f_s^{(\alpha,\beta)} - f_p^{(\alpha,\beta)})^2}{f_p^{(\alpha,\beta)}} + w_3 \sum_{(\alpha,\beta,\gamma)} \frac{(f_s^{(\alpha,\beta,\gamma)} - f_p^{(\alpha,\beta,\gamma)})^2}{f_p^{(\alpha,\beta,\gamma)}} \qquad (2)$$

where also the frequencies of occurrence of digraphs and trigraphs, $f^{(\alpha,\beta)}$ and $f^{(\alpha,\beta,\gamma)}$, are involved[6]; w_1, w_2 and w_3 are certain weighting factors, undetermined at present, representing the varying importance of each term.

The noisiness of the information is simulated by over-writing a given percentage of basic elements by other (or sometimes the same) ones, at random. The aim of this procedure is to find the minimum redundancy necessary at different noise-levels so that it is still possible to decipher the Morse code. Fig. 1 shows the nature of an expected diagram. The curve represents the average relationship between noise-level (*NL*) and minimum information content (*MIC*) of messages. We note that it may well be idealized in the sense that even noiseless messages cannot always be recognized without errors, and there could exist a certain amount of 'irreducible' error.

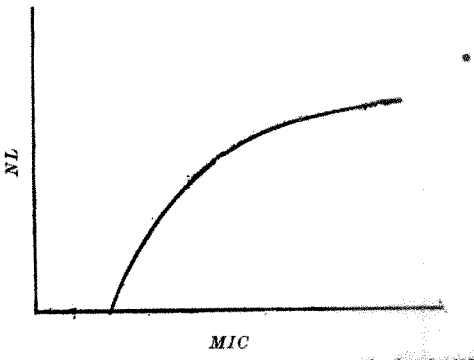

Fig. 1. Expected average relationship between noise-level (*NL*) and minimum information content (*MIC*) of messages

Influence of Motivation, Perception and Attention on Age-related Changes in Short-term Memory

THE responses made by young normal adults to various methods of dichotic stimulation have been investigated and reported by Broadbent[1]. His observations have led him to postulate that both perceptual and storage mechanisms are necessary for the correct sequential recall of such simultaneous stimulation.

I have put forward the hypothesis that since increasing age in normal individuals also seems to affect learning capacity, and as such impairment may also depend on changes in some short-term storage process, it could be anticipated that responses to dichotic stimulation might also show associations with age.

Broadbent has suggested that the first half-set of digits recalled from each dichotic span does not involve the storage process. If age primarily affects storage then the reproduction of the first half-set recalled should not be affected by advancing years. If the second half-set recalled must pass through the storage process then the recall of these digits should be affected by age. Investigations by Inglis and Caird[2] and Mackay and Inglis[3] show that this appears to be the case.

The results of these two experiments, carried out on different subjects (total No. = 280) by different experimenters, proved to be in very close agreement. As age increases there is little or no significant impairment in the ability to recall the half-spans reproduced first. Progressively and significantly greater difficulty is, on the other hand, shown in the reproduction of the second half-spans as age advances. Furthermore, the longer the span

to be recalled the greater the difference, overall, between the first and second half-spans.

These findings make it seem quite unlikely that differences in motivation can explain such changes in short-term storage with age. It is not easy to conceive how overall changes in motivation as people grow older could make them respond accurately to one ear but not to the other.

It could, however, be maintained that the impairment shown by elderly subjects in the recall of dichotic digits might be due to a failure to hear, or a failure to attend to, the second half-spans on which they showed most errors of report. We have accordingly carried out a further experiment in order to evaluate these possibilities; a preliminary report of our results is offered here.

One hundred and twenty subjects between 11 and 20 years of age were tested. There were 20 people in each decade group: 10 male and 10 female. They were required to recall dichotic digits under three conditions; these being: (1) when the order of recall was left to the free choice of the subject; (2) when the ear order of recall was specified before; (3) after these digits had been delivered.

Condition (1) was used in order to provide a further repetition of the experiments carried out on similar groups by Inglis and Caird[2] and Mackay and Inglis[3]. It can be seen that no control was exercised by this condition over the laterality of the order of recall. The results of this part of the experiment were in accord with previous findings.

In condition (2) the side to be recalled first was indicated by means of a signal panel set in front of the subject simply bearing the printed words 'right' and 'left'; a red light was switched on above the appropriate word by the experimenter, in this case immediately before each span of the dichotic digits was delivered. This condition was used in the experiment recorded here to evaluate the notion that the changes with age which had previously been shown on this task might be due, for example, to an age-related hearing loss in one ear as compared with the other. If it were the case that as people grow older they tend to suffer such a differential loss in auditory acuity then the apparent deficit in the ear recalled second under conditions of free response might be explained by this kind of peripheral difficulty. If, however, an increased order effect were to appear with age regardless of ear-specification, then this hypothesis would not be supported.

The results obtained under this condition refute the notion that any unilateral decrease in auditory acuity could account for the appearance of the order effect noted under conditions of free recall. A marked age-related recall order effect appears which is relatively independent of ear laterality.

In condition (3) the side to be recalled first was again specified by means of the light signals, in this case immediately after the dichotic digits were delivered. This procedure provided a control for the possible effects of differences in attention between the different age groups. It might be argued, for example, that previous findings were due to the fact that as people grow older they will, in the dichotic digit experiment, only pay attention to the material coming into one ear. If, however, the subjects only know after the digits have been delivered which side they have to report first and, further, if they only attend to one side, then the ear order effect should vanish, or at least be greatly diminished, since they cannot know beforehand to which ear they should have paid most attention.

Under this condition the age-related order effect was again clearly shown; the main decline with age being in the half-sets recalled second. This means that the order effect cannot be entirely explained by the notion that older subjects only attend to the material presented to one ear.

In conclusion, therefore, it may be said that the results of this experiment confirm, once again, that the responses made to dichotic stimulation under conditions of free recall are affected by age. Since it is the order effect which is exaggerated in older subjects this finding lends support to the view that some short-term storage mechanism is affected by advancing years. This finding cannot be explained in terms of differences in motivation with age. The results obtained in this experiment when the order of recall was specified before delivery of dichotic digits are similar to the results from free recall. Since the age-related order effect still appears regardless of which side is specified for recall first, this finding is quite incompatible with the notion that changes in responses to dichotic listening with age might be due, for example, to some unilateral hearing loss which gets worse as people grow older. This finding cannot, therefore, be explained in terms of differences in sensation or perception. The results obtained when order of report was specified after the delivery of the digits are also very similar to the results obtained under conditions of free recall. This outcome runs completely counter to the view that the changes observed with age might be due, for example, to the fact that older individuals only attend to the material from a single channel under conditions of simultaneous stimulation. This finding, therefore, cannot be explained in terms of differences in attention.

All these findings are, however, compatible with the hypothesis that the age-related impairment shown in recall under the three experimental conditions is due to a decline in the efficiency of some short-term memory storage process.

The work described was supported by grant 25 of the Ontario Mental Health Foundation; the testing was carried out by Mrs. Mary Ankus.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 5

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS, JOINT I.E.R.E.–I.E.E. MEDICAL ELECTRONICS GROUP (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 2.30 p.m.—Discussion on "Transistorized Biological Amplifiers".

BRITISH SOCIETY FOR THE PHILOSOPHY OF SCIENCE (at University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. R. Harre: "The Limits of Formalization".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at Shell Centre Theatre, Shell Centre, London, S.E.1), at 6.30 p.m.—Scientific Film Evening.

Tuesday, October 6

INSTITUTION OF THE RUBBER INDUSTRY, LONDON SECTION (at the Royal Society of Tropical Medicine, 26 Portland Place, London, W.1), at 5.30 p.m.—Mr. A. E. Moulton: "Rubber Springs"; 7 p.m.—Dr. H. J. Osterhof: "Isoprene and Polyisoprene Production at Goodyear—an Achievement of Bench-Scale Research".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Annual Meeting 6.30 p.m.—Mr. J. S. Clarke: "The Outlook of an Engineer on Social Problems" (Chairman's Address).

Wednesday, October 7

COLOUR GROUP (Great Britain) (in the Physics Department, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7), at 3 p.m.—Dr. J. E. Pinney: "Computational Colour Photography". 3.45 p.m.—Miss M. Hayward, Miss A. M. Mitchell and Mr. D. A. Pavey: "Colour Teaching Methods".

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. A. N. Burton: "Geological Mapping of the Province of Calabria, Southern Italy" (Demonstration); Dr. C. G. Adams: "The Foraminifera and Stratigraphy of the Melinau Limestone, Sarawak, and its Importance in Tertiary Correlation"; Dr. N. J. Snelling and Dr. R. B. McConnell: "Age-Determinations from British Guiana".

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W.1), at 5.15 p.m.—Dr. Cuthbert Dukes and Mr. D. A. Brunning: "The Origin and Early History of British Cancer Research Institutions"; Dr. D. H. Trapnell: "Man's Understanding of the Lymphatic System".

INSTITUTE OF PETROLEUM (at 61 New Cavendish Street, London, W.1), at 5.30 p.m.—Mr. A. T. J. Hayward: "Compressibility of Hydraulic Oils".

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6 p.m.—Dr. A. C. Copisarow: "The Contribution of the Engineer to the Economy".

INSTITUTION OF MECHANICAL ENGINEERS, INDUSTRIAL ADMINISTRATION AND ENGINEERING PRODUCTION AND STEAM PLANTS GROUPS (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. J. A. Rogers and Mr. R. C. Brewer: "Faults in Cast Components for High-Press/High-Temperature Service".

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Introductory meeting of the Packaging Group.

SOCIETY FOR ANALYTICAL CHEMISTRY (at the School of Pharmacy, Brunswick Square, London, W.C.1), at 6.30 p.m.—Prof. H. J. Emeleus, F.R.S.: "Analysis in Modern Inorganic Chemistry".

BRITISH INTERPLANETARY SOCIETY (at 4 Hamilton Place, London, W.1), at 7 p.m.—Mr. F. W. Forbes: "Expandable Structures for Missile and Space Applications".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at the Royal Institution, 21 Albemarle Street, London, W.1), at 7 p.m.—Dr. M. F. Perutz, F.R.S.: "The Anatomy of Haemoglobin" (Third Humphry Davy Lecture).

Wednesday, October 7—Thursday, October 8

INSTITUTION OF MECHANICAL ENGINEERS, PROCESS ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1)—Symposium on "Plastics and the Mechanical Engineer".

Thursday, October 8

ROYAL INSTITUTION OF NAVAL ARCHITECTS (in the Weir Lecture Hall, 10 Upper Belgrave Street, London, S.W.1), at 5 p.m.—Dr. R. Hurst: "Ship Research" (Fourth Amos Ayre Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. O. W. Humphreys, C.B.E.: Inaugural Address as President.

Friday, October 9

UNIVERSITY OF LONDON (in the Main Lecture Theatre, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. J. Kolff (Cleveland Clinic, Ohio): "Life Without Kidneys and Heart".*

Monday, October 12

INSTITUTION OF AGRICULTURAL ENGINEERS (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 10.15 a.m.—Mr. B. M. Camm: "Some Aspects of the Economic Utilization of Farm Machinery"; Mr. H. G. Pryor: "The Development and Application of High Power Units in Agriculture"; Mr. J. D. Savage: "Significant Features of Fuels and Lubricants for the Winter Use of Diesel-Engined Tractors".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. E. N. Davies: "Application of Electronic Vector Scanning Techniques Applied to Height-Finding Landing Systems"; Miss E. Killick: "Frequency Scanning Aerial Systems".

UNIVERSITY OF LONDON (in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. John Szentágothai (Medical University of Budapest): "The Neuronal Circuits of the Cerebellar Cortex".*

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Living Pattern" (Colour Films).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Ewell County Technical College Faraday Society, at the Ewell County Technical College, Reigate Road, Ewell, Surrey), at 7 p.m.—Mr. A. D. S. Tantrum: "Energy Production".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER IN CONTROL ENGINEERING—The Registrar, University College of North Wales, Bangor, North Wales (October 9).

RESEARCH STUDENTS (with an honours degree, G.R.I.C., Dip. Tech.) IN THE DEPARTMENT OF CHEMISTRY, to investigate branching and cross-linking reactions in polymerization processes—Prof. G. M. Burnett, University of Aberdeen, Old Aberdeen, Scotland (October 10).

LECTURER IN MECHANICAL ENGINEERING (Applied Thermodynamics, Mechanics of Fluids); a PRINCIPAL LECTURER IN ELECTRICAL ENGINEERING (Circuit Theory); a SENIOR LECTURER IN ELECTRICAL ENGINEERING (Light Current Engineering); a LECTURER IN CIVIL ENGINEERING; a LECTURER IN INORGANIC CHEMISTRY; a LECTURER IN APPLIED PHYSICS; a SENIOR LECTURER IN MATHEMATICS (Numerical Analysis); and a LECTURER IN MATHEMATICS—The Principal, Lanchester College of Technology, Priory Street, Coventry (October 12).

RESEARCH ASSISTANTS (with a university degree or diploma in technology with first- or second-class honours) to work in the following fields: analytical chemistry, physico-organic chemistry, applied physics, light current electrical engineering, control or ultrasonics—The Principal, Lanchester College of Technology, Priory Street, Coventry (October 12).

TECHNICIAN IN THE DEPARTMENT OF PHYSICS, University of Natal, Pietermaritzburg—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, October 12).

SCIENTIFIC OFFICER (with a first- or good second-class honours degree in physics and an interest in the application of physical methods to biological problems) at the Meat Research Institute, to work in collaboration with the Anatomy Department on physical methods of determining the composition of live animals and carcases, in particular ultrasonics and photogrammetry—The Secretary, Low Temperature Research Station, Downing Street, Cambridge, quoting vacancy No. 64/4 (October 13).

ASSISTANT LECTURER (with a special interest in experimental psychology) IN PSYCHOLOGY—The Registrar, The University, Manchester, 13 (October 16).

LECTURERS (3) (with a sound academic record, well qualified in anatomy or related sciences, and preferably some experience in teaching at university level) IN ANATOMY at the University of Queensland, Brisbane, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 16).

SENIOR LECTURER (with experience as an applied geophysicist and preferably with a strong background in geology) IN GEOPHYSICS at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 16).

SENIOR EXPERIMENTAL OFFICER (preferably with a degree or equivalent) IN THE DEPARTMENT OF MECHANICAL ENGINEERING to assist in the carrying out of research over a very wide field of interest—The Academic Registrar, The Queen's University, Belfast, Northern Ireland (October 17).

PROFESSOR OF CHEMISTRY and HEAD OF THE DEPARTMENT, University of Auckland, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 19).

M. C. SMITH LECTURER IN PATHOLOGY (Cancer Research)—The Assistant Registrar, The Medical School, The University, Birmingham, 15 (October 20).

GRADUATE (with an honours degree or equivalent in horticulture, agriculture or science) IN THE HORTICULTURE DIVISION, for mushroom research—The Director, An Foras Taluntais (The Agricultural Institute), 33 Merrion Road, Dublin 4, Republic of Ireland (October 21).

LECTURERS/ASSISTANT LECTURERS (2) (with a university degree in agricultural science, veterinary science or science) IN DAIRY HUSBANDRY/SHEEP HUSBANDRY at Massey University of Manawatu, Palmerston North, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 21).

DEMONSTRATORS (2) (with a degree in pharmacy, preferably with honours, and registered pharmacists) IN PHARMACY at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 23).

ASSISTANT (human geographer with a special interest in the urban field, preferably historical and morphological aspects) IN GEOGRAPHY—The Secretary of University Court, The University, Glasgow (October 24).

ASSISTANT LECTURER IN BIOCHEMISTRY—The Secretary, University of St. Andrews, College Gate, St. Andrews, Fife, Scotland (October 24).

PROFESSOR OF ORGANIC CHEMISTRY—The Registrar (Room 22, O.R.B.), The University, Reading (October 24).

LECTURER or ASSISTANT LECTURER IN BIOCHEMISTRY in the Faculty of Agriculture, Makerere University College, Uganda—The Secretary, University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 25).

LECTURER (with a degree in veterinary science with postgraduate experience in the field of pathology) IN PATHOLOGY at the University of Queensland, Brisbane, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 30).

CENTRAL ELECTRICITY GENERATING BOARD RESEARCH FELLOW (with a higher degree) IN THE DEPARTMENT OF NATURAL PHILOSOPHY, to undertake full-time research in a field of physics related generally to some of the Board's interests in nuclear power, for example, neutron and gamma ray physics, effects of radiation on materials, etc.—The Secretary of University Court, The University, Glasgow, W.2 (October 31).

CHAIR OF ELECTRICAL SCIENCE IN THE SCHOOL OF ENGINEERING SCIENCE—The Registrar, University of Warwick, Coventry (October 31).

LECTURER (graduate of medicine or science) IN THE DEPARTMENT OF ANATOMY—The Assistant Registrar, The Medical School, The University, Birmingham, 15 (October 31).

LECTURERS (2) IN CHEMISTRY at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

PROFESSOR OF PHYSICAL CHEMISTRY at the University of New South Wales—The Agent General for New South Wales, 56–57 Strand, London, W.C.2; and The Appointments Section, The University of New South Wales, Box 1, Post Office, Kensington, N.S.W., Australia (October 31).

SENIOR LECTURER and LECTURERS IN GEOGRAPHY at the University of Western Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, October 31).

UNIVERSITY TUTOR IN MICROBIOLOGY—The Secretary, The Queen's University, Belfast, Northern Ireland (October 31).

PROFESSOR OF ANTHROPOLOGY at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 4).

RESEARCH FELLOW (specialist in geomorphology, and preferably with an interest in the geomorphological applications of sedimentology) IN THE DEPARTMENT OF GEOGRAPHY, Institute of Advanced Studies, Australian National University—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 4).

LECTURER IN PHYSICAL CHEMISTRY and a LECTURER IN ORGANIC CHEMISTRY at the University of Western Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Australia and London, November 7).

PROFESSOR OF PSYCHOLOGY at Victoria University of Wellington, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 11).

SECOND CHAIR OF MATHEMATICS; and SECOND CHAIR OF PHYSICS—The Registrar, University of East Anglia, Earlham Hall, Norwich, Norfolk, NOR. 05G (November 16).

CHAIR OF MECHANICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (November 30).

CHAIR OF PURE MATHEMATICS; and CHAIR OF APPLIED MATHEMATICS at Monash University, Melbourne—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1; or The Registrar, Monash University, Clayton, Victoria, Australia (November 30).

ASSOCIATE PROFESSOR (preferably with research interest in vertebrate biology, ecology or behaviour) IN ZOOLOGY—The Chairman, Zoology Department, McGill University, Montreal, 2, Canada.

BIOLOGISTS (2) (graduates in biology with first- or upper second-class honours degree, or with a Ph.D.) for work involving the study of environmental factors in the production of human chromosome aberrations, chromosome studies on the general population, the study of subjects with abnormal autosome and sex chromosome complements, the study of leukaemias and the investigation of the action of viruses—The Director, M.R.C. Clinical Effects of Radiation Research Unit, Western General Hospital, Edinburgh, 4.

CHAIR IN SOCIOLOGICAL STUDIES—The Registrar, The University, Senate House, Bristol, 2.

CHAIR OF ZOOLOGY—The Registrar, University Senate House, Bristol 2.

CHEMIST or BIOCHEMIST (with an interest in proteins) to carry out fundamental research into the molecular structure of collagen—The Director of Research, The Gelatine and Glue Research Association, 2a Dalmeny Avenue, Holloway, London, N.7.

RESEARCH ASSISTANT for studies involving the chemical estimation of urinary steroids including use of the gas chromatograph—The Director, Department of Clinical Endocrinology, Birmingham and Midland Hospital for Women, Showell Green Lane, Birmingham, 11.

RESEARCH ASSISTANTS in the following subjects: mechanical engineering (or production engineering); electrical engineering (control system techniques, activation network theory, sampled data systems, logic switching circuits, or a topic of mutual interest to be determined); industrial sociology (psychology or economics); chemistry (surface chemistry or colloids); biology (microbial genetics of the feeding of micro-arthropods or micro-organisms); pharmacy (pharmacology or pharmaceutical economics) at the City of Liverpool College of Technology—The Director of Education, Education Offices, 14 Sir Thomas Street, Liverpool, 1.

RESEARCH FELLOW (organic chemist) for work on the use of metal chelates as reagents in organic synthesis under the direction of Dr. R. P. Houghton—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff.

RESEARCH STUDENT (graduate of a British university with a good honours degree, or holder of G.M.R.I.C. at an equivalent level) IN THE DEPARTMENT OF CHEMISTRY, for research in the field of adsorption of vapours by active charcoals and the preparation of such charcoals from novel sources—The Registrar, The University, Hull.

SENIOR ASSISTANT IN RESEARCH or ASSISTANT IN RESEARCH, to work on the micro-palæontology of deep-sea sediments, with opportunities for work at sea—The Secretary, Department of Geology, Downing Street, Cambridge.

REPORTS and other PUBLICATIONS

THE "JUST PUBLISHED" SECOND EDITION

STATISTICAL METHOD IN BIOLOGICAL ASSAY

D. J. FINNEY, M.A., Sc.D., F.R.S.

Professor of Statistics in the University of Aberdeen
Director of the Agricultural Research Council Unit of Statistics

668 pages 22 figures 105s. net

A familiarity with the details of assay design and analysis is today necessary to many statisticians working as consultants in biological and medical research and in the production of foodstuffs, drugs, etc. Prof. Finney's book provides a comprehensive account of designs and statistical analyses for biological assays, both as a textbook for the student of statistics and as a work of reference for the practitioner of bioassay.

In this second edition, with only a small increase in the number of pages, a considerable amount of new material has been introduced to cover recent developments, and the references have been extended and brought up to date.

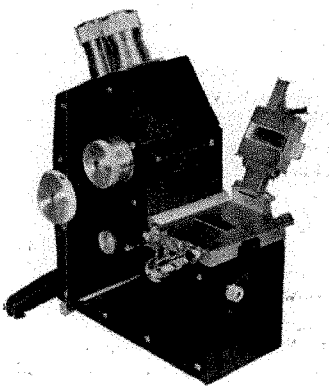
CYGNET meets the demands of science



Murex Ltd., Rainham. Architects: P. Edmé & Partners, A.R.I.B.A., London

We equip many of this country's most important laboratories. Progressive design, superb craftsmanship and versatility of arrangement contribute to the maximum efficiency of our installations. Specially selected timbers are used for our furniture and we can supply single units or complete installations at highly competitive prices. Our design experts work in close collaboration with the architect in the submission of plans. And Cygnet's complete consultative service is always available.

PLANNING FOR THE DEVELOPMENT DECADE

LORD BRAIN, in his presidential address to the British Association at Southampton (*Nature*, 203, 943; 1964), referred to the growth of population as an outstanding example of our failure to predict and prepare for the consequences of scientific development. While it was fairly generally recognized that there was every prospect that the world population would have doubled from 3,000 million to 6,000 million by the year 2000, 10–15 per cent of that population were now living on a diet with insufficient calories, and 50 per cent were either undernourished or malnourished, or both. To raise this standard of living and to provide it for twice the present number was an inescapable challenge, which, as Lord Brain pointed out, has implications for water supply, roads, industry, education and, indeed, all that makes possible a full life. Yet Britain has no population policy and has given no thought to the implications of the present rate of growth.

Lord Brain instanced the position of medical education as one example of Britain's lack of foresight and her failure to use existing knowledge, but he made a percipient comment on the redistribution of leisure which would follow the expansion of automation. The population problem is, however, an international problem which can only be dealt with effectively at an international level, and in addressing the British Association on this point, Lord Brain reiterated what he had said in a debate in the House of Lords on world population and family planning on July 1. What is needed is an international body, sponsored by the United Nations Organization, to collect all available demographic information (and promote the search for it when necessary), to take into account present and prospective supplies of food and water and the economic and cultural needs of growing populations, and to review all present-day scientific work on population control. The United Nations is already doing something to meet these needs, through its Population Commission and the Population Branch of the Bureau of Social Affairs. The United Nations and six of its specialized agencies are sponsoring another World Population Conference in 1965. Nevertheless, Lord Brain thought that all this did not provide the essential combination of diagnosis and treatment, and he pleaded for greater initiative from the British Government, particularly in support of the recognition of the International Planned Parenthood Federation by the Economic and Social Council.

It is worth noting, in passing, that Lord Brain's remarks as to the implications of population growth in various fields found some support in an address which Mr. A. A. L. Caesar delivered in opening a symposium on "Regional Planning Problems in Great Britain" at the British Association meeting on August 28. In calling for more Government action in this matter, instead of leaving it largely to voluntary organizations, Lord Brain had welcomed the statement made earlier in the debate by the Earl of Dundee, that the Secretary for Technical Co-operation had informed some Commonwealth and foreign Governments, as well as some colonial Governments, that Britain was willing to apply to family planning exactly the same principles as govern her aid generally, and would seek to respond to requests for technical assistance made by overseas Governments. The Earl of Dundee added that Britain was prepared to consider sympathetically any proposals for assisting the developing countries, where this problem was pressing, and that the Government thought that technical assistance through the United Nations should be available to States desiring to spread the idea and practice of voluntary family planning.

The Earl of Dundee had outlined the Government's views early in the debate, which was opened by Lord McCorquodale of Newton. The latter had quoted extensively from a report presented by Dr. Prebisch to the United Nations Trade and Development Conference at Geneva in the summer, and referred also to the concern expressed in the last report from the Consultative Committee on the Colombo Plan that the rapid rate of increase in population might in some areas more than offset the development effort. A similar opinion had also been expressed by Mr. Eugene Black, until recently president of the World Bank. Lord McCorquodale stressed especially the importance of effective communication of knowledge of the problem: this was too large a task to be left to the undeveloped and poorer countries, and should be given high priority by the United Nations.

An early start should be made now to plan and build up, throughout the world, adequate maternal and child welfare services, of which education in family planning would be an integral part. The International Planned Parenthood Federation had sought to promote such a plan, but it needed the support of the United Nations and the World Health Organization—especially in the field of research, which Lord Brain later stressed. Research is required into the present facts of economic growth and effective methods of controlling fertility, suitable for different societies and religions, and for different levels of education. On the last-mentioned issue there was an immediate response from the Bishop of London, who agreed as to the importance of education, and suggested that, in the face of 87 million children in South and South-east Asia without facilities for elementary education, and the further 130 million children in these areas to be educated by 1980, it might be wise to consider a temporary lowering of Western educational standards, and channel our efforts to supply more teachers to those areas. He referred to the world appeal for literature which the World Council of Churches was sponsoring in this field and to the importance of the education of women, as well as to the need for a reconsideration of traditional moral theology.

As is usual on such subjects in the House of Lords, the debate maintained a high level of informed discussion and constructive criticism. The Earl of Listowel, who was somewhat critical of the Government's support in

the past, referred, for example, to the help which Sweden had given to Ceylon in implementing family planning. Lord Casey was concerned especially with India and Pakistan, and repeated the plea for more scientific research. He referred to the help given by the Rockefeller Foundation and the Ford Foundation, which during the past twelve years have spent some millions of dollars in support of research on human reproduction. It should be remembered here that the population problem and the conquest of hunger are now two of the five main objectives of the Rockefeller Foundation.

This debate was in some measure a sequel to an earlier debate in the House of Lords on June 24 when Lord Henderson directed attention to the vital importance of the United Nations Development Decade, and in particular to the United Nations International Conference on Trade and Development at Geneva, which had then just completed its three months session. In this debate, which perhaps sustained an even higher level than that on July 1, reference was freely made to the report of the Secretary-General of the United Nations, *The United Nations Development Decade: Proposals for Action**, submitted to the Economic and Social Council in consequence of a resolution of the General Assembly on December 19, 1961. That resolution designated the present decade as the United Nations Development Decade. In this period it was hoped that member States and their peoples would intensify their efforts to mobilize and sustain support for the measures required to accelerate progress towards self-sustaining growth of the economy of the individual nations, and towards their social advancement. For each under-developed country an objective was suggested of a minimum annual rate of growth of aggregate national income of 5 per cent by the end of the decade.

In the foreword to his proposals, the Secretary-General observes that development concerns not only man's material needs, but also the improvement of social conditions and of broad human aspirations: development is not just economic growth; it is growth plus change. Moreover, while it may be possible for the developing countries to compress the stages of growth through which the developed countries have passed, it may also be necessary to re-examine the methods by which the development may be attained. U Thant recognizes that we have now at our disposal such effective instruments as the International Bank and the International Monetary Fund, the International Development Association, the United Nations Special Fund, the Expanded Programme of Technical Assistance, and various special programmes such as the World Food Programme and the United Nations Children's Fund, the resources of which may require strengthening. However, he made it plain that he is equally prepared to adopt new instruments as new problems and new opportunities emerge.

The basic problem is to find ways in which the advanced countries can effectively help the developing countries, and new methods of technical co-operation which take full advantage of the new economic and technological possibilities are required. The main economic objective is to create conditions in which the material increases of the developing countries will be increasing by 5 per cent annually by 1970 and will continue to expand at this rate. If this can be done, even if the populations of these countries continues to rise by 2–2·5 per cent a year, personal living standards can be doubled within 25–30 years. However, if growth of population is more rapid this will take correspondingly longer.

U Thant believes that this objective for 1970 is within our reach, provided there is willingness to make the necessary efforts and sacrifices, and in justification of this optimism he refers to the increasing appreciation of the need for new approaches. These include the concept of national planning—for social as well as for economic development; greater insight into the importance of the human factor in development, and the urgent need to mobilize human resources; and acceptance of the principle of capital assistance to developing countries. Concerning the last-mentioned, he visualizes a level of 1 per cent of the national incomes of the advanced countries being made available during the decade. He also suggests that more progress would be possible if the main industrial countries directed as much attention to promoting trade as to dispensing aid. Hindrances to the entry of their products into industrial markets, and the expansion of the production of many primary products faster than demand, are largely responsible for the disappointing foreign trade record of the developing countries: here the related problem of stabilization of the international commodity markets also requires solution.

Increasing under-employment and unemployment is another serious problem and far-reaching action will be needed. Again, many developing countries lack any detailed knowledge of their resources and it is estimated that expenditure on pre-investment work must rise to about 1,000 million dollars a year, or, by 1970, about double the present rate, if the objectives of the decade are to be achieved. A crucial area is the surveying and development of natural resources, including water, minerals and power, while too little effort has been directed towards solving the social and technological problems of the developing countries, although many of them appear to present no insurmountable difficulties. Closely linked is the availability of skilled personnel: the shortage of highly skilled personnel, rather than a shortage of material resources or finance, may well be the greatest obstacle unless new steps are taken. Here U Thant stresses the need for foreign experts to participate in establishing institutions which will take over and continue their work when they leave.

This foreword well illustrates the scope of the Secretary-General's proposals, in which, incidentally, the briefest section is that concerned with technical co-operation. Here, however, U Thant stresses the vital importance of co-operation, and the fact that it must be based on the transfer and exchange of knowledge, with closer relations between scientists in the developing and the developed countries. He looks for new methods of linking the research problems of the developing countries and the research possibilities of the industrialized countries, and it is unfortunate that in the House of Lords no one took up this question of overseas research. Certainly this should not simply be left to the United Nations Educational, Scientific and Cultural Organization or to the Foundations and other institutions of the United States. On technical assistance generally, U Thant recognizes the need for effective co-ordination of effort, and the proposals indicate that the lessons of the previous decade have been learnt and are being turned to account.

Lord Henderson, in opening the debate on June 24, had quoted the secretary-general of the Conference, Dr.

* United Nations: Department of Economic and Social Affairs. *The United Nations Development Decade: Proposals for Action*—Report of the Secretary-General. Pp. xii+125. (New York: United Nations; London: H.M. Stationery Office, 1962.) 1.25 dollars; 9*s*. 6*d*.

Prebisch, who had stressed the danger of world-wide tension if the present situation was not matched by a vigorous policy of economic and social development in which international co-operation must play a decisive part. In some of the developing countries human rights were being set aside as a luxury which they could not afford, and as a hindrance to the essential plans for social and economic development. World poverty confronted us, therefore, with the challenge as to whether our Western standards, our values, and our democratic way of life had any meaning for the developing countries. It was a moral challenge, but it was also self-interest to make it one of the priorities of our policies to help the poorer countries to help themselves.

While being concerned with the lack of progress since the programme was launched in 1961, Lord Henderson insisted that the greatest single service that developed countries could render was to provide expanding markets for the products of the developing countries at stable and remunerative prices, thus enabling them increasingly to pay for their essential imports. Like U Thant, he maintained that aid through trade was the healthiest way to proceed, and he quoted ten key points which Mr. E. Heath had urged in his first speech at the conference on "Trade and Development" which should receive particular attention: (1) a standstill in new barriers to trade with less-developed countries in products identified as being of particular importance to them; (2) ending quantitative restrictions adversely affecting the trade of developing countries; (3) removal of duties on tropical products; (4) removal of duties on primary products from developing countries; (5) reduction of tariffs on semi-processed and processed products from developing countries; (6) ending internal taxes and revenue duties applying specifically to products wholly or mainly produced in developing countries; (7) granting preference to developing countries; (8) exchange of preferences among developing countries; (9) stabilization of commodity prices; (10) supplementary financial assistance. What was done on these points would, Lord Henderson suggested, provide a useful yardstick by which to judge the success and value of the Conference. A statement had already been made in both Houses on June 16, when the Conference ended, and in this it was stated that recommendations concerning aid for development included one, initiated by the British Government, inviting the International Bank for Reconstruction to examine the feasibility of a new scheme for multilateral aid, to be administered under the International Development Association, and designed to help countries the development programmes of which were threatened by adverse export trends which could not be adequately dealt with by short-term balance of payments support. The statement also indicated that, at a conference in the autumn, Britain would announce an increase in her contribution to the Special Fund and to the expanded programme of technical assistance for 1965; that, with other Western countries, she was willing to support an increase in the United Nations budget which would permit expansion of the activities of the Secretariat in industrial development; that she was willing to provide capital assistance to the African Development Bank and to examine sympathetically the possibility of assisting other regional development banks, including the Inter-American Development Bank.

Lord Drumalbyn, who followed Lord Henderson, explained that although it had been expected that the text of the resolutions of the Conference would be available for the debate on June 24, it would not, in fact, be available before June 29. The Government would present them to Parliament in a White Paper in due course. Annexed to the Final Act would be the observations and reservations made by individual delegations on certain recommendations, and the recommendations, after consideration by the Economic and Social Council in July, would be submitted to the Assembly of the United Nations meeting during November 1964–February 1965.

The Conference formulated a set of fourteen general principles governing international trade relations and trade policies conducive to development; however, on some of these Britain had important reservations. The new institutions established—including the Conference itself as a permanent organization of the General Assembly, a Trade and Development Board, and a special committee to be appointed by the Secretary-General—were charged with responsibility of producing a set of principles that would be fully acceptable internationally. There were also important discussions on shipping and insurance issues. Outstanding was the former, which led to the formulation of a "Common Measure of Understanding", stressing the value of liner conferences and suggesting the establishment of consultation machinery between shippers and such conferences. Priority was urged for port improvements, and the development was welcomed of merchant fleets in emergent countries where they had been established on an economic basis.

In the debate, a maiden speech from Lord Hawick of Glendale was notable for the way in which he drew on his own wide experience, and illustrated the possibility of developing secondary industries and assisting small farmers to farm scientifically. He also stressed the importance of discovering the appropriate technique in helping emergent countries. The Bishop of Chichester referred particularly to the place and importance of voluntary effort in technical aid, while in a penetrating speech Lord Lindsay of Birker emphasized the importance of technique and understanding, particularly the encouragement of a general scientific attitude and a readiness to try experiments in the under-developed countries. Lord Lindsay and Lord Hawick were largely supported by the Earl of Selkirk and Lord Walston, the latter stressing particularly the need for craftsmen and technicians as well as professional people. The Earl of Iddesleigh underlined the importance of voluntary service and Lord Sandys reminded the House that foresight and imagination were essential if aid and effort were not to be wasted: here he quoted Prof. L. Dudley Stamp's criticism concerning the fact that the Aswan high dam was already out of date because of the huge loss of water by evaporation: the water should have been brought by pipe-line from the mountains.

The question of a Ministry of Overseas Development was again raised, but here Baroness Gaitskell found little support, and although Lord Sandford, who stressed particularly the opportunity for voluntary service, referred to the need for a clear policy which was deliberately set forth, consistently applied and publicly supported, did not touch on organization at this level, Viscount Samuel had reservations and did not favour a Minister of Overseas Development, although he agreed that mass co-ordination of overseas activities was needed. The Earl of Listowel, however, supported Baroness Gaitskell on this point, but his main argument was that the wealthy countries should work out a common trade policy which

would give the poorer countries a larger share of world trade, and in replying on the debate, apart from pointing out that the magnitude of the British effort was often not appreciated, essentially endorsed most of the points that had been made about voluntary effort, trade and the supply of skill.

Almost simultaneously with Lord Brain's reference to this whole question of aid to the developing countries, the August number of the *OECD Observer* included an article on the role of trade with developing countries which explained the significance to members of the Organization for Economic Co-operation and Development of the United Nations Conference on Trade and Development. Even closer to Lord Brain's argument about the growth of population and its implications are two articles published in the summer 1964 issue of *Daedalus*. This issue is devoted to four disparate, though not entirely unrelated, themes: population, prediction, conflict and existentialism, and in the first of two articles on population, H. Hoagland discusses the mechanisms of population control, arguing that only by fundamental changes in our way of thinking can the population problem be solved. He is not pessimistic although he admits that family planning and limitation call for a critical level of education and prosperity which is not now found in the very poor countries.

Prof. Jean Mayer in his article "Food and Population: the Wrong Problem?" is more challenging and argues that it is unwise, if not dangerous, to link the population problem too closely with food. His argument runs very close to that of Lord Brain. He points out that there are other shortages which are likely to become critical, besides food supply, if we do not start urgently to face the situation, The whole weight of his article lies behind Lord Brain's assertion that our greatest need to-day is to acquire the power of looking ahead, forecasting and preparing for the consequences of the accelerating developments in science and technology.

Nevertheless, Prof. Mayer is emphatic that we need also to make effective use of the knowledge that we already have. This is not to deny that more knowledge is still needed in many fields or to disparage a further article in *Daedalus* in which Prof. D. Bell outlines twelve nodes of prediction. Knowledge may be wasted for lack of the right technique for its use. These articles and debates in sum, however, illustrate the timeliness of Lord Brain's observations and the urgency that the utilization of Britain's resources of materials and manpower should be tackled with all the insight and skill that existing knowledge permits, and also with the most effective tools and techniques that modern technology has placed at the service of the planner and the administrator. It is no longer a matter of whether to plan but how to plan most effectively.

SOVIET ANTARCTIC RESEARCH

Soviet Antarctic Expedition
Information Bulletin, Vol. 1: Pp. xv+404. 90*s*. Vol. 2: Pp. x+318. 80*s*. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.)

SOME scientific reports of Antarctic expeditions take a notoriously long time to appear. Two scientific reports from pre-First World War expeditions have appeared within the past two years, and publication is not yet complete. Reports of inter-war and post-Second World War expeditions are similarly incomplete. (I have myself one such report on my conscience!)

In these circumstances, the shorter paper or brief preliminary report has much to commend it, both for the reader, who obtains a general picture of work carried out, and for the investigator, who establishes without much delay his claim to have contributed to knowledge at a particular time. This problem has been tackled in various ways. The Antarctic Research Programme of the U.S. National Science Foundation publishes a monthly *Antarctic Report* summarizing reports from the field. The British Antarctic Survey now publishes its *Bulletin* at irregular intervals, but this is mainly intended for shorter final reports. Annual reports of National Committees on Antarctic Research to SCAR (the Scientific Committee on Antarctic Research of the International Council of Scientific Unions) present useful summaries of present and proposed activities in the Antarctic, but these are not widely available.

The Soviet Antarctic Expedition, which has been in operation since 1955, has solved the problem in a useful manner by producing *Informatsionnyy Byulleten Sovetskoy Antarkticheskoy Ekspeditsii*, which has appeared at irregular intervals since 1958, the latest being No. 46. Issues average 50–60 pages in length, including illustrations, and include about ten short scientific articles many of which summarize work of considerable interest. There are also brief observers' notes on items of interest, summaries of radio messages from Soviet stations in the Antarctic and such items as recommendations of various Antarctic meetings, notes of work of other countries, reviews of books, maps, etc. An English index in each volume has served to direct those without a knowledge of Russian to articles for which they need a translation, but in spite of this aid it has been difficult for non-Russian scholars to gain a general appreciation of the scope and standards of Soviet researches in Antarctica.

The initiative of Dr. George P. Wollard and the University of Wisconsin, aided by a grant from the National Science Foundation, in translating the Soviet *Bulletin* has made this general preliminary survey accessible to English readers. Final editing has been done by Scripta Technica, Inc., and the first two volumes now published by Elsevier cover *Bulletins* Nos. 1–20 (1958–60).

A spot check shows that care has been taken in the translation, and the English language presentation is good. No errors of translation were noted; a couple of unimportant sentences were omitted. The system of transliteration is reasonably consistent though it differs from that of most map makers. Retransliteration of proper names is a fruitful source of errors, and a few minor errors of this type were noted, for example, *W*. Fuchs for *V*. Fuchs, Argentina Islands for Argentine Islands. Two errors, one of them unimportant, were found in five large tables.

The translation is not 'cover-to-cover', but deals with all the main scientific papers. The section called "By Radio from Antarctica" has rightly been omitted as ephemeral, while "Observers' Notes" have been translated only when they are of particular interest. The maps are photo-reproductions of the originals with new letterpress superimposed as necessary for the English language reader. Some are over-reduced, for example, I, p. 81, while half-tone reproductions are poor—but so are the originals in the Russian version.

A third volume in the series is due shortly, presumably covering *Information Bulletins* Nos. 21–30. It is to be hoped that the response will be sufficient to encourage the promoters to catch up on the backlog and to continue with a speedily available translation of future numbers. Close co-operation between the Russian editors and the translators and publishers could ensure that this interesting *Information Bulletin* receives the notice it warrants in other countries. If this can be arranged at the present reasonable price, a very useful service will be provided.

G. de Q. Robin

PHILOSOPHICAL AND SCIENTIFIC METHOD

Philosophy of Science

The Delaware Seminar, Vol. 2, 1962–1963. Edited by Bernard Baumrin. Pp. xviii+551. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1963.) 109*s*.

THIS is the second volume of the Delaware Seminars and it confirms the expectations aroused by the first, presenting a true image of philosophical activity, one of continual debate that constantly questions old assumptions and results (and, be it said, some not so old); a kind of dialogue between contending personalities, rather than an accomplished set of results. This volume is specifically devoted to problems in the field of the physical sciences—or rather, in physics; chemistry still does not seem to attract the philosophical minds of the present day. Part 2 discusses topics falling under the heading of space, time and relativity; Part 3 is on particles, fields, and quantum mechanics; Part 6 on cosmology. These parts are matched by others of a more general nature, going over some of the bread-and-butter ground of the academic philosophy of science.

Part 1 is perhaps the most interesting, with its attempts at the wholesale demolition of philosophical doctrines which had their heyday, it seems, only yesterday, such as 'logical empiricism', 'hypothetic-deductive theories', requirements for explanation in terms of precision and completeness, or the exclusion of probabilistic approaches from any final point of view. All these assumptions are questioned vigorously. P. K. Feyerabend's chapter in part goes over ground covered in some of this author's earlier writings, but it considerably clarifies his position, which is more clearly seen to have been motivated by an attempt to make the Anti-Copenhagen spirit of physicists like Bohm and Vigier methodologically respectable. The older logical empiricism made use of certain idealized models for theory construction, with certain implicit logical criteria, such as those of consistency and meaning invariance. The reality is (and, Feyerabend insists, certainly ought to be) different. One must not imagine that existing theories can be tested against a background of a certain set of given neutral observational 'facts'. Rather, theories must be tested against alternative theories, and these must first be formulated, so that some of the critical 'facts' (observed, or more often inferred) shall first be forthcoming. Ultimately, these alternative theories need not be mutually consistent, nor need the meanings of the terms which they contain (theoretical as well as empirical) all have fixed connotations.

Wilfrid Sellar's chapter goes into the problem of the reality of theoretical entities by way of the elegant method of a discussion of the nature of the correspondence rules of various kinds which co-ordinate the 'abstract' with the 'empirical' expressions of some given theory, or even the theoretical properties of two different theories, for example, physical and chemical, thus involving incidentally a clarification of the notion of 'reduction' of one to the other.

Part 4 contains the usual expected section on 'inductive inference', and an important paper on the theory of measurement by Brian Ellis. The former, by W. C. Salmon, makes another stab at the so-called 'pragmatic vindication' of induction. This it does in terms of Reichenbach's probabilistic approach, using the frequency concept of probability (sequence of a limit). It purports to prove that the 'rule of induction by enumeration' can be shown to give successful results, provided that the ratio of observed sample values to size of sample has a limit at all (a kind of 'uniformity of nature' maxim) and shows that any competing alternative rules would fail to give successful results, even if the maxim did hold, since they can be shown to sin against a number of necessary logical requirements for success. Of course, this is a vindication only if 'Nature is uniform', and if one limits oneself to a discussion of very simple numerical cases.

Of the specialist sections, I can only single out A. Gruenbaum's attempt to show, by means of an example from relativity, something of the importance of clear philosophical ideas when we try to solve certain questions in the history of science; Hilary Putnam in turn criticizes some of Gruenbaum's anti-conventionalist views on geometry. In Part 2, Hill, Pais and Suppes consider such matters as "the status and applicability of mathematics in physical theories, the plethora of elementary particles, and the non-standard character of the mathematical equipment of quantum mechanics".

In Part 6 N. R. Hanson and J. A. Wheeler contribute discussions on philosophical aspects of contemporary cosmologies; Wheeler's paper, despite a pretty clear beginning (straightforward almost to the point of being bizarre), turns out to be heavily technical.

The contributors to these Seminars, by and large, are leaders in their field, and though no one reader would be likely to follow each and every one of the discussions with equal interest, the standard is uniformly high, even though occasionally it seems as if old wine was being poured into new bottles. Certainly these colloquia try to keep alive the old dream of worth-while discussion between scientist and philosopher without the traditional British depreciation of the other man's interests, knowledge, and intellectual traditions.

G. BUCHDAHL

SPACE MEDLEY

Advances in Space Science and Technology

Vol. 5. Edited by Frederick I. Ordway, III. Pp. xvii+334. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 93*s*.

THIS book, like the first four volumes in the series, brings together articles on widely varied aspects of space science and technology, and it is pleasant to be able to report that this fifth volume maintains the high standard of its predecessors.

The book is divided into six chapters. The first, by R. G. Athay, is a useful short survey of what is not known about the Sun, with ideas for experiments. The second chapter, by R. P. Haviland, discusses techniques for communication satellites. The various possible systems are described, and the important technical problems are clearly stated; there is also a section on the world's desire to communicate and the best ways of assuaging it. The next chapter, by H. W. Ritchey and J. M. McDermott, is a fine review of solid-fuel rocket technology: all aspects of the subject, from detonation tests to the geometry of grain design, are covered in a readable and authoritative text. The fourth chapter, by R. E. Smith, is a thorough survey of the problems of keeping man alive and well during prolonged space flights: such possibilities as hibernation or transient hypothermic torpor are mentioned, and there is an illuminating discourse on the regenerative treatment of waste products. Writers on the subject of man-in-space should, however, beware of wrapping simple facts in layers of abstraction. The news that "very complex matrices of interlocking life systems . . . find their common denominators in terms of mutual requirements for energy . . ." may induce in the reader a "transient state of hypothermic torpor", from which he emerges with the suspicion that the author merely means "all living things need food and warmth".

The last two chapters of the book are the longest, and range widely. Chapter 5 deals with navigational and geodetic satellites, and their applications both on Earth and elsewhere in the Solar System. The historical survey of navigation and navigation-satellites, by J. D. Nicolaides, is particularly good, and brings to light many unfamiliar facts. The section on geodetic satellites, by J. D.

Nicolaides and M. M. Macomber, is satisfactory, though the examples quoted are not always the best. The contribution by W. M. Kaula, who discusses how satellites should be used to investigate the gravitational fields of the Moon and planets, is an excellent introduction to a difficult subject.

The final and longest chapter, of nearly 100 pages, is by K. A. Ehricke, on "Orbital Operations": this is not concerned with surgery under weightless conditions, but with the "controlled change of conditions of a technical system in space". Biological terms do appear, however, as is quite natural since space vehicles, like animals, can propel themselves and execute purposeful actions: thus we find discussion of "coupling, docking and mating". Dr. Ehricke's chapter is a masterly survey of what may well be going on in space in twenty years time when operations in cislunar and interplanetary space may be as routine as airline schedules are now. Occasionally Dr. Ehricke falters over points of detail, but this does very little to reduce the value of his survey.

The book is well printed and produced, with good indexes and only a sparse crop of misprints. The jacket strikes a slightly false note: a moonscape on the dust cover may be better than a dust cover on the Moon, but the lunar scene shown is too unrealistic for a soberly scientific book. This superficial blemish does not prevent the book being an admirable addition to the literature of lasting interest on space science and technology.

D. G. King-Hele

A SURVEY OF KRON'S THEORIES

Tensors in Electrical Engineering

By J. W. Lynn. Pp. x+216. (London : Edward Arnold (Publishers), Ltd., 1963.) 52*s*. 6*d*.

WITHIN the compass of about 200 pages, the author of *Tensors in Electrical Engineering* gives quite a detailed survey of Kron's application of tensors to electric networks and machines. He is firmly convinced that tensors are an essential feature of the unified theory of electric machines.

A brief first chapter summarizes the necessary groundwork of determinants and matrices, after which Dr. Lynn plunges at once into Kron's network analysis. Tensors are described and used early in the book without excessive use of geometry. From the development of a set of general equations describing the performance of a generalized machine, Lynn proceeds to the equations of actual types by derivation from the general equations.

A substantial proportion of the book is devoted to hunting, and the analysis of a two-machine system is given in full. It is pleasant to see that stability tests were carried out on a laboratory two-machine system, and the results compared with the theoretical calculations. Although the author's principal topic is electric machines, he includes in his final chapter a fairly comprehensive treatment of Kron's circuital models of the electromagnetic field equations.

This is by no means a book for beginners. It is aimed at postgraduate students of electric machines and research workers in this field. For such readers, it is probably not too difficult if they are already conversant with the subject. The book is obviously the culmination of many years of research and reflexion. The text is clear and concise. Lynn shares Kron's philosophy and follows his methods very closely with, however, less reference to geometry. He proceeds with ease and assurance through the more difficult parts of the mathematics.

It is necessary to pass now from praise to protest. The second chapter opens with a figure showing two simple static networks the power inputs of which are patently unequal. A transformation matrix which is singular (three rows and two columns) is also displayed. Yet the author opens his mathematical analysis of the two networks by equating the unequal power inputs. A few lines later, he uses the inverse of his transformation matrix which obviously has no inverse. There are other holes in the theory, but these two will suffice. The author is well aware of them and indeed discusses them: it is sobering to reflect that he can muster support for such avoidable subterfuges. The theory is bad and should be abandoned; Kron's technique is so impressive and so successful that it merits a rigorous theory.

W. J. Gibbs

ELIMINATION FROM THE BODY OF RADIOACTIVE ISOTOPES

Radioactive Metal Mobilization in Medicine

By Prof. Alexander Catsch, translated from German by Dr. Bergene Kawin. (Springfield, Illinois: Charles C. Thomas, 1964.) 7.50 dollars.

THE ever-increasing peace-time production and use of radioactive substances, including metals, together with the potential hazard of their extensive release in time of war, have brought a greater danger of accidental contamination to those handling these substances and otherwise exposed to them. The elimination of radioactive isotopes from the body, before they have had time to become irreversibly fixed to the tissues, calls for the use of every available means.

The author reviews, in *Radioactive Metal Mobilization in Medicine*, the present-day methods of removal of radioactive metallic isotopes, restricting his observations to a few of the metals likely to be encountered in the laboratory and to those which have so far been investigated. Attention is directed mainly to the use of chelating agents which the author regards as the most promising substances for this purpose. After a description of the chemical structure and probable mode of action of chelating agents, there follows a discussion of the results of their use under experimental conditions in animals. Although most of the present knowledge of this subject is based on animal experiment, it is probable that much of the information so gained is applicable to man, as the action of chelating agents depends very largely on physico-chemical forces. The author is, however, careful to point out that some of the experimental results may not apply to man.

The first attempts at heavy-metal elimination from the body date from the use in man, some 30 years ago, of calcium salts and parathormone in an attempt to remove lead incorporated in the skeleton. A similar competitive action using a stable isotope to dilute a radioactive isotope bound to body-tissues is still used, but has to a great extent been replaced by the use of complexing (chelating) agents. Of the chelating agents at present in use, the polyaminopolycarboxylic acid group offers the most promise. Much work still remains to be done to improve the complexing properties of chelating agents for individual isotopes, and the problem of toxicity of both chelator and its metal complex has prevented many active substances from becoming therapeutic realities.

The removal of radioactive isotopes from the body requires not only an understanding of the probable action and structure of complexing agents, but also a knowledge of how individual isotopes are stored in and eliminated from the tissues. The effectiveness of any chelating agent in binding a metal in any particular organ varies considerably and has to be established by experiment. Furthermore, a chelating agent used to complex with a given radioactive isotope may be found to complex with other metals, producing such serious effects as the removal of zinc from carbonic anhydrase and iron from succinic anhydrase.

Prof. Catsch also considers factors influencing the effectiveness of chelating agents, such as delay in their administration and the effects of competition with endo-

genous acceptor groups. Such factors may prove of great importance, because the rate of irreversible fixation of a radioactive isotope within individual body-tissues determines whether any form of treatment is likely to prove effective. The inability of some chelating agents to pass from one body compartment to another also seriously detracts from their efficiency; this has led to a search for improved complexing agents by chemical substitution of the side chains in existing substances.

The most probable routes of human contamination by radioactive metallic isotopes are thought to be by implantation into wounds and absorption through the respiratory tract, and experimental work bearing on the elimination of isotopes absorbed through these two routes is discussed.

Although most attention has been directed to chelating agents as the most promising means of eliminating radioactive isotopes from the body, alternative means, such as combining the metals to form insoluble products and their hormonal release from the skeleton, are also reviewed.

Finally, the author considers the still very meagre data concerning the removal of radioactive metallic isotopes from man, and concludes by showing how fragmentary is the present state of knowledge about the whole subject and how much still remains to be discovered.

This short work is a succinct and clear account of the present state of knowledge of radioactive metallic isotope elimination, and nothing of the clarity of the original account appears to have been lost in translation.

H. SPENCER

NUTRITION OF MAN AND HIS FARM ANIMALS

Comparative Nutrition of Man and Domestic Animals

By H. H. Mitchell. Vol. 1: Pp. xxi+701. 178*s*. 6*d*. Vol. 2: Pp. xxi+840. 200*s*. (New York and London: Academic Press, 1964.)

THIS substantial work by Dr. H. H. Mitchell, whose international reputation rests in several fields of research, but in none more than in the nutritional aspects of proteins and amino acids, is most timely. It correlates, in a quantitative fashion, the nutrient requirements of man and his domesticated livestock, and the factors which modify these. *Comparative Nutrition of Man and Domestic Animals* is a thoroughly critical and stimulating book, as are all Dr. Mitchell's reviews. The emphasis is on the physiology and biochemical aspects, rather than on the more practical.

As the author describes in his preface, this work arose in the preparation and revision throughout some thirty years of a postgraduate course in comparative nutrition, held by him at the University of Illinois. However, in parallel with the development of the formal course, an experimental research programme was pursued on the material and energy requirements of poultry, pigs, sheep, cattle, and, in later years also, of man himself.

The similarities and dissimilarities among the different species are pointed out, and Dr. Mitchell has provided background information, largely biochemical in nature, concerning the various nutrients, their functions and their participation in the energy transactions of the body. The courses which led to these two volumes were designed for students in nutrition, physiology, domestic science and animal science.

Net nutrient requirements, that is, the amounts requiring to be absorbed by a completely healthy animal, are expressed in terms of animal expenditures and storages, factored in their ultimate terms of maintenance, growth, activity, reproduction, etc. These net requirements are converted into dietary requirements, after due consideration of the wastages of dietary nutrients in the course of their assimilation in the body.

The actual preparation of these volumes took place on Dr. Mitchell's retirement from active service, and it is very heartening to know that the University of Illinois, in its wisdom, provided facilities, including office space.

The first volume deals with the nutrient requirements of the animal body, in terms of energy, protein, water, minerals, and with the nutrient requirements for muscular work, growth and senescence, storage, reproduction, lactation and egg production. The second volume deals with vitamin requirements in terms of dietary equivalents, the wastage of dietary nutrients during assimilation and net nutrient values.

In combining the assessed nutrient expenditures or storages involved—in growth, activity, reproduction, lactation, etc.—to obtain a total nutrient requirement of an animal of given species, age, sex and physiological status, Mitchell warns against assuming that the whole is the sum of the parts, because the imposition of one function on another may result in stimulation or inhibition of one, or both, functions. Thus, pregnancy stimulates basal metabolism, while inhibiting lactation.

Mitchell defines a balanced diet as one containing amounts and proportions of each of the essential nutrients large enough to promote maximum performance of those animal functions with respect to which the diet is balanced, but not so large as to impair, in any way, the well-being of the animal consuming it or of any of its tissues, or to depress the net energy content of the diet. He defines the carbohydrate and fat content as one sufficient in amount to permit the full use of the essential nutrients to perform their specific functions in the body. The utilization of the metabolizable energy of a completely balanced diet is maximal, and the same for all such diets for each animal function, but varies from species to species. The corollary of this is that the nutritive value of feeds is specific and characteristic for the various feeds only with respect to their content of nutrients and their digestibility. The degree to which the absorbed nutrients are utilized in the body is dependent on the way in which feeds are combined and the animal functions they support.

The more of such a balanced ration that is consumed, the better nourished the animal will be, with reference to which the ration is balanced up to the point of repletion of its requirements, but, in agriculture, the law of diminishing returns has generally to be taken into account and, at some stage, an input/output relation has to be struck in the light of present-day economic circumstances.

Superimposed on the apparent fixity of nutritional behaviour among different species, there are secondary and specific modifications that reflect adaptations to different environmental conditions. These are the modifications that distinguish one species from another. Within any one species, adaptations to changes in environment and in food supply may occur in relatively short spaces of time. These necessitate the conception of a nutrient requirement as a range of values, symmetrically including a mean measure, rather than the mean itself. Nevertheless, this conception does not hold for net requirements because these are what have to be absorbed.

Because of lack of necessary nutritional data, little consideration can be given to some domestic species, such as the cat and dog. The author makes a strong case for the profitability of the investigation of farm animals in furthering the investigation of human nutrition.

To end the second volume there is a strong philosophical note, and this is what we would expect from a life-study of the resultant of satisfying the integration of factored requirements.

Each chapter has its own extensive bibliography and there is a complete author and subject index. The author and his publishers are to be congratulated on a magnum opus which will long remain a standard reference book, as well as being full of dynamic thought and criticism.

D. P. CUTHBERTSON

Matrix and Tensor Analysis in Electrical Network Theory

By S. Austen Stigant. Pp. 505. (London: Macdonald and Co. (Publishers), Ltd., 1964.) 80*s*. net.

THIS book presents the subject of network theory in a manner which was originally largely due to Gabriel Kron.

The volume is divided into three parts; theory, applications and appendixes. The first part, approximately one-third of the book, comprises introductory chapters on determinants and matrices, followed by three chapters on diagonalization of matrices. The three final chapters of this part develop tensors in relation to electrical networks.

The second part, again approximately one-third of the book, is taken up with applications in power distribution and engineering. A chapter on simple applications of determinants is followed by three on matrix applications, the examples being largely connected with three-phase systems. Examples on untransposed and transposed conductor systems, with and without faults, are given in later chapters. The application of tensors to multi-phase networks, multiple-winding transformers and automatic voltage control by series capacitor is considered in the concluding chapters of this second part.

The third part contains appendixes on material needed in the course of development of the second part, but unconnected with the main theme of the book. The treatment used in these appendixes is largely classical.

The book is well written, easy to follow and is directed at engineers rather than applied mathematicians. The latter would be rather unimpressed with the introductory chapters on matrices and tensors. The book should prove very useful to engineers who are interested in the modern treatment of power distribution systems and, possibly, to honours graduates studying heavy current electrical engineering in departments having an enlightened approach to the subject. The large number of practical examples included in this volume should make it more attractive to the less-academically inclined than some of the earlier treatises on matrices and tensors in network theory.

Handbuch der Physik

Herausgegeben von S. Flügge. Band 27: Spektroskopie 1. Pp. vi + 507. (Berlin, Göttingen und Heidelberg: Springer-Verlag, 1963.) 130 D.M.

THIS volume, the first of the two on spectroscopy in the *Handbuch der Physik*, contains three articles. The titles (which are in the languages used), authors and lengths of these are as follows: "Line Widths", R. G. Breene, jun., of Centerville, Ohio (pp. 79); "Atomic Spectra", Bengt Edlén of Lund (pp. 140); "Spectroscopic électronique moleculaire", Boris Rosen of Liège (pp. 253).

R. G. Breene is the author of the well-known book *The Shift and Shape of Spectral Lines* published in 1961. As would be expected from this, his article, which covers molecules as well as atoms, contains a clear account of many of the relevant mathematical researches. The more recent work does not, however, receive as much attention as it merits; thus, of the 95 references cited, 62 are dated 1939 or earlier, 15 are in the period 1940–49, 18 are in the period 1950–59 and none are later than this.

Bengt Edlén himself points out that "Atomic Spectra" is less comprehensive than the title suggests. It is indeed concerned mainly with the undisturbed gross structure of the energy-level systems of free atoms and ions. A considerable part of the material, especially that concerning isoelectronic sequences, is original. The article will be consulted for many years.

In "Spectroscopic électronique moleculaire", Rosen provides a much-needed outline of the principal theoretical and experimental investigations of diatomic and polyatomic molecules. The article is a valuable addition to the literature of the subject. A defect is that the bibliography is not so full and as carefully compiled as might perhaps be wished. There are useful appendixes by W. B. Price on ionization potentials, by K. Wieland on the spectra of radicles and by F. W. Dalby on absolute transition probabilities.

The book concludes with German-English and English-German subject indexes of all three articles, and a French subject index of the last article. The production is of a high standard. In particular, praise must be given to the anonymous artists responsible for the numerous beautifully drawn figures. D. R. Bates

Theorie et Technique de la Radiocristallographie

Third edition. By Prof. A. Guinier. Pp. xvi + 740. (Paris: Dunod, 1964.) 124 Fr.

THE first edition of this admirable text-book appeared in a paper-covered form in 1945. An English translation was published in 1952, but was soon superseded by a much enlarged and almost entirely rewritten second edition in French. The third edition, just published eight years later, is not enlarged but has been brought up to date by the addition of new references and some changes in text and tables. The binding and paper are good, but unfortunately many of the photographs are still very badly reproduced and some minor drafting inaccuracies remain in line drawings. In spite of these perennial criticisms, however, there is no doubt that this book is a classic, and that the author's French is so beautifully clear that it is a pleasure to read.

The five main parts of the book deal with the general properties and practical production of X-rays; elementary crystallography and diffraction theory; experimental diffraction techniques for powders and single crystals; applications to various practical and theoretical problems; and, finally, diffraction by imperfect crystals and amorphous bodies, including small-angle scattering. Problems of crystal structure determination are confined to about eight pages. For systematic treatment in that field there are many good text-books; but there is no other text-book having the range and the quality of *Theorie et Technique de la Radiocristallographie*. K. Lonsdale

The Waterfowl of the World, Vol. 4

By Jean Delacour. With contributions by Hildegarde Howard, Milton W. Weller, Philip S. Humphrey and George A. Clark, jun. Pp. 364+15 plates. (London: Country Life, Ltd., 1964.) 126*s*. net.

THE first three volumes of this work, published between 1954 and 1959, gave a systematic account of the Anatidae, species by species (*Nature*, 185, 567; 1960). This final volume reviews the group as a whole, thus complementing the extensive presentation of facts by a valuable synthesis. Here Jean Delacour plays a mainly editorial part, although himself writing chapters on aviculture and on domestic waterfowl. The major contributor is Milton W. Weller, who provides the review of the biology of the family in four chapters dealing with general habits, the reproductive cycle, ecology, and distribution and species relationships. The same writer is also responsible for chapters on fowling and on conservation and management, while P. S. Humphrey and G. A. Clark deal with the anatomy of waterfowl and Hildegarde Howard with fossil Anseriformes. Four of the colour plates by Peter Scott portray domesticated forms derived from the greylag goose, the swan goose, the Muscovy duck, and the mallard; the other—a somewhat unusual feature—pictorially corrects errors in the artist's illustrations of wild species in the earlier volumes. The procedure of adding a full general review to the systematic treatment is much to be commended, and the work as a whole forms an admirable monograph of a large and cosmopolitan family of birds.

A NEW INTERPRETATION OF THE GEOLOGY OF BRITISH GUIANA

By Dr. R. B. McCONNELL, C.B.E.
Formerly Director, Geological Survey of British Guiana*

Dr. E. WILLIAMS
Senior Geologist, Department of Mines, Hobart, Tasmania†

Dr. R. T. CANNON
Senior Geologist, Geological Survey of British Guiana, Georgetown
AND
Dr. N. J. SNELLING
Age Determination Unit, Overseas Geological Surveys, Department of Geology and Mineralogy, University of Oxford

PROVISION from the Colonial Development and Welfare Fund enabled the Geological Survey of British Guiana to carry out an intensive mapping campaign during the years 1957–61 (ref. 1) with the object of reporting on the advisability of further mineral search by airborne and other modern prospecting techniques. A new geological map, based on 1 : 125,000 geological cover, was ready in 1961 (now published in colour)[2], and formed the basis of a successful application to the United Nations Special Fund for assistance in an airborne prospecting campaign which began in 1962. The object of this article is to present briefly, pending the publication of detailed descriptions[3,11], the results of general interest regarding the structure and radiometric dating of the Guiana Shield and its similarities with West Africa.

British Guiana covers an important central segment of the Guiana (Spanish: *Guayana*) Shield (Fig. 1), the basement of north-eastern South America, divided from the Brazilian Shield only by the early Palæozoic downwarp of the Amazon River basin. Geological exploration was begun by the British Government in 1868 (ref. 4) and a great deal of information was accumulated during the growth of the Geological Survey previous to 1957, and described in various publications[5–7]. Mapping, following the re-organization of the Geological Survey, was based on strictly objective lines adapted to Precambrian terranes, and full use was made of the available photogeological cover supplied by the Directorate of Overseas Surveys. Representative specimens were carefully selected for radiometric dating which has since confirmed and extended the interpretations adopted and fixed the time-range of the major geological events as Lower Proterozoic or Archæan. Except for one age supplied by the Atomic Energy Division, Geological Survey of Great Britain[8], all the radiometric dates quoted are based on the work of the Age Determination Unit, Overseas Geological Surveys in the laboratory of the Department of Geology and Mineralogy, University of Oxford[9].

British Guiana (Fig. 2) can be divided essentially into three geological and geomorphic units as follows: (1) a narrow coastal strip of marine sediments of Cretaceous to Recent age; (2) the Pakaraima Mountains in the west, which are formed by the eastern margin of the tabular, detritic, Roraima Formation covering a large area in neighbouring Brazil and Venezuela; (3) a vast extent of low pediplains with occasional plateaux and mountains rising to 1,000 ft. and, rarely, 2–3,000 ft., covered, except for a strip of savannah in the south-west, with Amazonian rain-forest. This area is underlain by Precambrian metasedimentary and metavolcanic rocks, gneisses and granites with a sporadic cover of Tertiary to Recent sediments.

Geological and structural considerations indicate that the latter unit can again be divided into two geological provinces as defined by M. E. Wilson[10]. These northern and southern provinces are separated just south of latitude 4° N. by an east–west rift valley about 100 miles long and 30 miles wide which magnetometer observations suggest may contain up to 20,000 ft. of (?) Cretaceous–Tertiary sediments. East of longitude 58° 30′ the younger sediments disappear and granites and gneisses occur, but the relations of the major units are obscured by bodies of younger granite.

Table 1 shows the major geological formations in British Guiana in their stratigraphical succession as determined both by geological and structural considerations and by radiometric dating. The dates given are approximate minimum ages based on potassium/argon, rubidium/strontium and uranium/thorium/lead on a variety of minerals: a detailed discussion of the radiometric methods used and the geological significance of the various results is in the press[11].

The most widespread of the Precambrian formations of northern and central British Guiana is the Barama–Mazaruni Assemblage which is now shown to be essentially a eugeosynclinal accumulation of mudstones, greywackes and conglomerates, with fine-grained igneous rocks chiefly of the spilite–keratophyre suite, metamorphosed throughout in the greenschist facies, with local zones of higher grade[3,12]. Pillow lavas have been found in Venezuela[13] within the extension of these rocks, and occasional graded bedding throughout the succession has served to disentangle the stratigraphy and indicate a structural style of open folding, with axial directions mainly west-north-west–east-north-east, and a well-developed, steeply dipping foliation sometimes discordant to the fold trend. A field trip to the upper Cuyuni and Yuruari River basins, kindly arranged by the Venezuelan Government, enabled

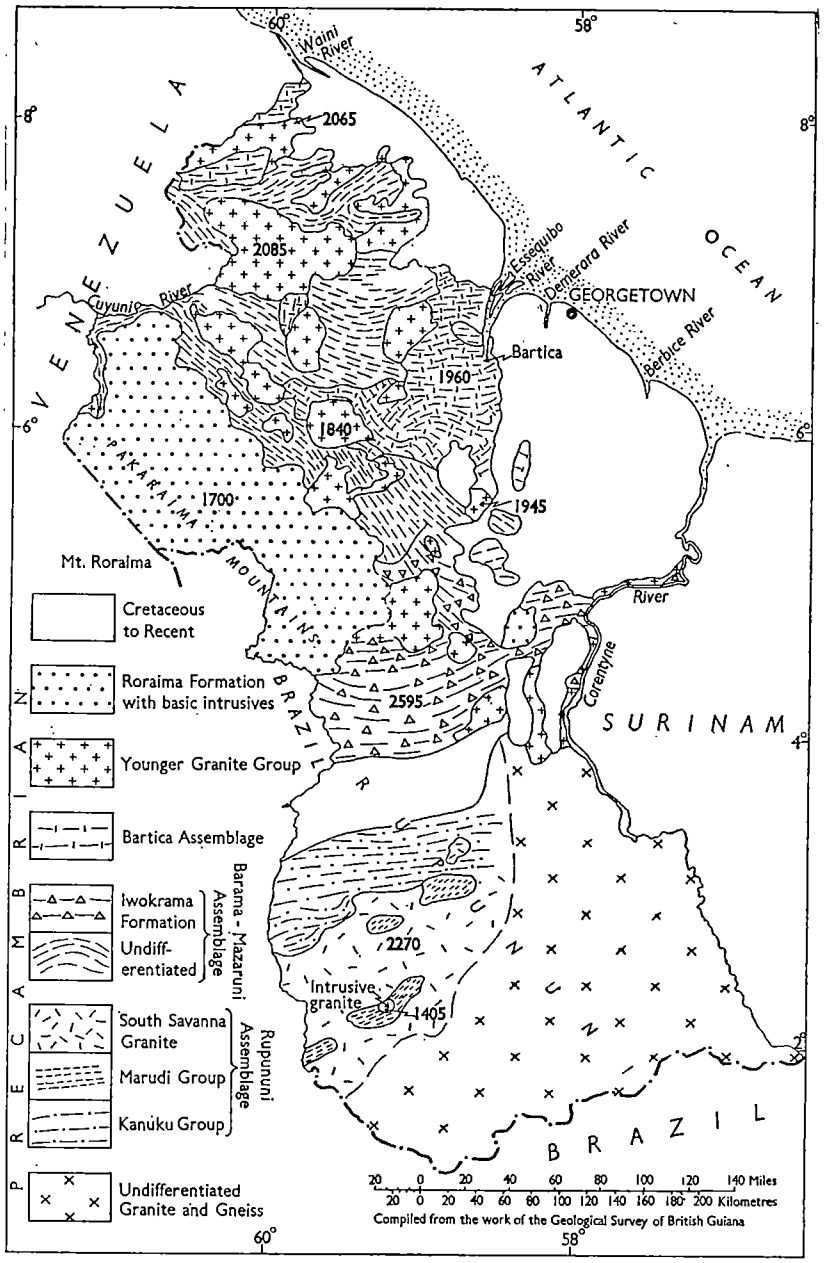

Fig. 2. Generalized geological map of British Guiana showing trendlines and minimum radiometric ages (million years) now accepted as significant for particular groups of rocks

two of us[14] to affirm the extension of the geosynclinal régime to the west-north-west, and this has now been established. In the opposite direction, to the east and east-south-east, similar formations have been described in Surinam[15] and, in some detail, in French Guiana[16], where radiometric dating supports this provisional correlation. A minimum age of about 2,500 million years[11] for the final filling of this geosyncline is tentatively suggested by a firm potassium/argon determination (2,595 ± 125 m.y.) on riebeckite from a granite[18] cutting the Iwokrama Formation.

The margin of this approximately east–west geosynclinal basin containing the Barama–Mazaruni Assemblage, the gneisses and granites of the Bartica Assemblage and Younger Granite Group is unknown to the north, towards the Atlantic, but to the south it is marked by a change to more orthoquartzitic sediments (Muruwa Formation)[17] overlain by a great thickness of rhyolitic and dacitic volcanic rocks (Iwokrama Formation)[18]. These marginal formations appear to follow a wide arc through Brazil to the Rio Caura area (7° N.; 65° W.) in Venezuela where they have now been recognized[19,20]. Thus the existence of an older land mass, now represented by the Rupununi Assemblage, which was postulated on other geological and structural grounds[21], is now supported by information on the sedimentological zoning of the Barama–Mazaruni Assemblage.

The Archæan Barama–Mazaruni eugeosyncline, therefore, forms a belt about 350 km wide along the Atlantic coast of the Guiana Shield, and appears to be cut approximately lengthwise by the present coastline.

Emplaced in the eugeosynclinal prism are bodies of crystalline rocks consisting chiefly of biotite and hornblende-biotite gneisses with amphibolites which have been grouped as the Bartica Assemblage[22], so named from the type area where the rocks have been examined in more detail. These gneisses were originally mapped as an ancient basement; but geological, structural and sedimentological arguments, later supported by radiometric evidence, have shown that they are probably derived by

Table 1. STRATIGRAPHICAL TABLE FOR BRITISH GUIANA

With significant minimum radiometric ages

RECENT TO CRETACEOUS		Superficial		Sands, clays and laterite
		Corentyne and Rose Hall groups		Marine clays and sands
		Takutu Formation		Red and grey shales and sandstones, in Rupununi District only
			GREAT	UNCONFORMITY
PALAEOZOIC		Minor Intrusives		Dolerites, etc. 450 m.y. in Rupununi
			GREAT	UNCONFORMITY
		Younger Basic Intrusive Group		Dolerites and quartz dolerites in thick dykes and sill, about 1,700 m.y.
		Roraima Formation		Continental orthoquartzitic succession with shales and jasper
			GREAT	UNCONFORMITY
	Northern Province			*Southern Province*
PRECAMBRIAN		Younger Granite Group	Granite, grandiorite and adamellite complexes, about 2000 m.y.	
	BARTICA ASSEMBLAGE	Muscovite granite	Muscovite granite passing to muscovite biotite gneiss, about 2,000 m.y.	RUPUNUNI ASSEMBLAGE: South Savanna Group — Biotite granite with enclaves, about 2,300 m.y.
		Banded gneiss	Banded biotite and biotite-hornblende gneiss; amphibolites	Marudi Group — Metaquartzites, biotite schist and gneiss
				Kanuku Group — Hypersthene and biotite-garnet granulites; charnockitic gneiss and granite
	MAZARUNI GROUP	Haimaraka Formation	Mudstones and greywackes; volcanic rocks	
		Cuyuni Formation	Sandstones, pebbly sandstones and conglomerates of greywackes suite; volcanic rocks	UNCORRELATED: Kuyuwini Group — Rhyolitic and andesitic volcanic rocks in Southern Rupununi (age very uncertain)
		Iwokrama Formation *	Rhyolitic and dacitic volcanics, > 2,500 m.y.	Gneiss and granite — Widespread biotite and biotite-hornblende gneisses and granites in partially explored southern British Guiana
		Muruwa Formation *	Orthoquartzitic sandstones and acid volcanic rocks	
	BARAMA GROUP	Various Formations	Mudstones, quartzites, argillites; lavas and pyroclastics; manganiferous phyllites; mica schists and gneisses	

* Formations of continental margin, roughly equivalent in age to the eugeosynclinal Haimaraka and Cuyuni formations.

metamorphic–metasomatic processes from the metasediments and metavolcanics of the Barama–Mazaruni Assemblage during a period of tectonism. They may be regarded, following Wegmann[23], as an *Unterbau* of which the supercrustal Barama–Mazaruni rocks are the *Oberbau*. Granites, adamellites and granodiorites of the Younger Granite Group[24], mostly foliated, both conformable and cross-cutting, have also been emplaced in the eugeosynclinal succession and radiometric dating[9,11] relates them in time to the diastrophism reflected in the Bartica Assemblage.

The apparent ages of these gneisses and granites have been disturbed by later events, either diastrophic or thermal (for example, widespread intrusion of dolerites at about 1,700 m.y.), which have reconstituted certain minerals causing them to give ages younger than the age of original emplacement. We consider, however, that reliable potassium/argon determinations on pyroxene, hornblende and muscovite indicate a minimum age of about 2,000 m.y. for the close of this pre-Roraima period of metamorphism and granitization. Gneisses and granites generally regarded as occupying a similar stratigraphical position in French Guiana have been dated 2,200–1,900 m.y.[16].

The Rupununi Assemblage, forming the southern margin of the Archæan geosyncline, consists chiefly of the Kanuku Group of banded biotite, biotite–garnet and charnockitic gneisses, mostly in the amphibolite and, to a lesser extent, the granulite facies of metamorphism, the Marudi Group of mica schists and metaquartzites in the greenschist facies, and a large batholith of biotite granite, the South Savanna Granite, which has intrusive contacts with both groups[25,26]. Radiometric evidence based on uranium/thorium/lead ratios in monazite indicates a probable age of about 2,300 m.y. for the granite, thus tentatively fixing a minimum age for the assemblage. The rocks of the Marudi and Kanuku Groups have been migmatized by this granite, but the finely banded granulites of the Kanuku Group have suffered an earlier metamorphism and on structural and geological grounds are regarded as the oldest shield rocks known in British Guiana. Here again, the potassium/argon and rubidium/strontium isotope relationships in minerals of the granite have been disturbed by later events, probably including the emplacement of a completely mobilized granite dated about 1,400 m.y.[27], and tectonic stresses resulting in brittle faulting indicated by mylonite belts dated about 1,300–1,100 m.y.[25]. These difficulties in radiometric dating will be further discussed in the communication in preparation[11].

The quartzitic sandstones, quartzites and shales of the Roraima Formation[28] form a tabular succession, remarkably undisturbed, about 7,000 ft. thick[29], which, judging from its outliers, appears to have once covered some 1,200,000 km² in the centre of the Guiana Shield[30]. The age of this formation has been variously estimated as Cretaceous, Triassic, Palæozoic and late Precambrian. It is clearly younger than about 2,000 m.y. as it transgresses the Younger Granites, and older than the thick dolerite sills and dykes of the Younger Basic Intrusive Group[31]. Radiometric work on the latter, including a sill from high in the succession, and on mica from their contact hornfelses, has now given a radiometric age of *c.* 1,700 m.y.[32], based on a large number of potassium/argon and rubidium/strontium determinations, thus placing the Roraima Formation in the Lower Proterozoic of the Canadian classification. An earlier age[33] has been postulated but is not accepted by us. Radiometric work on dolerites from the southern province has given a middle Ordovician age (450 ± m.y.)[11].

Attention has already been directed to the lithological similarities between the manganiferous rocks of British Guiana and the Birrimian of West Africa[34]. The descriptions of Junner[35] show the recognition of graded bedding and pillow lavas, and other indications of a eugeosynclinal origin for the Birrimian. A close comparison, both lithological and structural, can also be made between the post-Birrimian granites and gneisses and the crystalline rocks of the Bartica Assemblage and the Younger Granite Group. The age of the deposition and folding of the Birrimian is not precisely fixed, but must be placed between that of the post-Birrimian granites, which have yielded many apparent ages in the 2,100–1,850-m.y. range[37–39], and the Sula Mountain schists of Sierra Leone which are dated approximately 3,000 m.y.[37]. Thus the Barama–Mazaruni and Birrimian eugeosynclines, both cut across by the present Atlantic coastline, could have been in continuity before a postulated Atlantic spreading. Ages of 2,600–2,550 m.y. have also been published[38,40] for a formation in Mauretania the relationship of which with the Birrimian is unknown. Lithologically the Roraima Formation, with its basic intrusives, though unfolded and unmetamor-

phosed, is similar to the Tarkwaian of Ghana and belongs to the same time-range. Comparison between the tabular marine Palæozoic of the Amazon basin and Brazilian Shield, and similar rocks in the Taoudeni and other West African basins, could also be fruitful.

We thank Prof. J. Sutton for his advice and the Directors of Overseas Geological Surveys, London, and the Geological Survey of British Guiana for their support and for permission to publish.

ORGANIZED ELEMENT DISTRIBUTION IN RELATION TO SIZE IN THE ORGUEIL METEORITE

By Dr. GEORGE CLAUS* and Dr EVA A. SUBA-C.*

Department of Chemistry, University of California, La Jolla, San Diego

IN 1961 Claus and Nagy reported that 1 mg of the Orgueil and Ivuna carbonaceous chondrites contained approximately 1,700 organized elements, respectively, which they thought to be microfossils of possible extra-terrestrial origin. This report was augmented by them[1] with similar observations conducted on the Alais and Tonk carbonaceous meteorites. The number of the organized elements in these meteorites was also reported to be about 1,350/mg. Briggs and Kitto[2] also found 1,000–1,700 stainable microstructures per mg of the Mokoia meteorite. Claus *et al.*[3], re-investigating the problem, came to the conclusion that approximately 90 per cent of the organized elements in any of the aforementioned meteorites is comprised of the most simple forms which they designated type 1 and type 2 (ref. 4). The greatest controversy, after their original report, centred round two points: (1) whether the seemingly very high number of the organized elements found by them could be substantiated, and (2) whether these simple forms, which they classified as type 1 or 2, have characteristics such that biogenic origin could be assumed for them. In the present report we will deal with these two problems.

Carefully weighed amounts of approximately 1 mg of the Orgueil meteorite were placed on precleaned microscope slides coated with fresh egg albumin or with a drop of glycerine. The sample on the albumin-coated slide was crushed and more or less evenly distributed on it by rubbing between the original slide and another also coated with albumin. After these slides were dried in an oven at 80° C, balsam was applied to them and they were covered with 18 × 18 mm precleaned cover slips. Each of these preparations thus contained about 0·5 mg of meteorite powder. The weighed samples in the glycerine drop were crushed with a glass rod and also cover-slipped. For counting the organized elements the glycerine preparations were used in which the amounts of the sample were exactly known. Counting was done with a Leitz 'Ortholux' microscope using a times 93 oil-immersion objective and a pair of times 25 wide field oculars. Each observational field in this apparatus measured 8·464 μ^2; the entire preparation thus corresponded to 325.153.024 μ^2 or 38.416 observational fields. The content of three slides was counted, one of them entirely, and half the other two. Counting was started at the lower left corner of the preparation and, by moving the stage towards the north, a row of fields was counted. After having reached the upper left corner of the preparation, the slide was moved by one observational field towards east, and starting from here, again a row of fields was counted by moving the stage towards south. When the south edge of the preparation was reached the same procedure was applied again, and thus field by field the entire slide was counted. The numbers obtained for the organized elements in the three different preparations were averaged and corrected so as to correspond to 1 mg of meteorite sample.

One of the slides coated with albumin was used for the measuring of organized elements. The microscopic set-up differed from that previously described only in the point of using times 12·5 oculars instead of the times 25 used previously. One of the oculars contained a calibrated measuring disk. A Leitz 'Orthomat' automatic photographic attachment was added to the microscope. The preparation was scanned somewhat more randomly than those used for counting, but care was taken that the same field never should be seen twice. An independent observer was trained to recognize the types 1 and 2 organized elements, and those which were selected by this observer were measured to the first tenth of a micron and were

* On leave from New York University, Medical Center, New York.

photographed. In this way 303 organized elements were randomly selected from a single preparation containing about 0·5 mg of meteorite. It was thought that this population is large enough and can be accepted as a representative sample of the meteoritic microstructures.

The experiment resulted in the recognition of 1,534 organized elements belonging to types 1 and 2 in mg of the Orgueil meteorite. The same high number reported earlier for a similar experiment[4] was challenged on two different grounds. Anders and Fitch[5] and Fitch and Anders[6] stated that such a high number, even if it contains all types of organized elements, is an over-estimation. Other workers, like Staplin[7] and Ross[8], were of the opinion that the number of the genuine organized elements—those which can possibly be accepted as microfossils—is very small and that a micropalæontologist would not consider forms like type 1 or 2 as representing fossil forms of life.

A simple division based on the previously enumerated facts shows that approximately every twenty-fifth microscopic field contains one organized element which certainly does not seem to be an over-estimation.

The second point to be discussed is more complex. Fitch and Anders[6] write: " 'Organized elements' . . . are a heterogenous group of particles which, in our opinion, are best classified into two types: those that have a highly structured morphology and those that have a much simpler appearance". They think that the forms belonging to their first category represent terrestrial contaminants, while the second group is composed of simple mineral grains. The electron-probe microanalyses conducted on different types of organized elements by Nagy *et al.*[9] clearly demonstrated that the particles are mineralized with iron and some chlorine; thus they are indigenous to the meteorites. This fact is even accepted by the aforementioned authors; however, Anders[10] is of the opinion that: "The case for their biological origin now rests entirely on their featureless morphology". They certainly dispute our results and those of others, demonstrating the presence of an acid-insoluble pellicle even in the types 1 and 2 organized elements (Engles—cited by Urey[11], Nagy *et al.*[1], Claus *et al.*[12], Palik[13], Van Landingham[14]). They also point out that the biological stains used by us[3]—widely accepted histochemical reactions used to demonstrate certain cellular components—when applied to the organized elements give ambiguous results. The investigations of Nagy *et al.*[15], on the ultra-violet absorption spectra of single demineralized type 1 organized elements, either in crushed preparations or in petrographic thin sections, indicating the presence of possible protein and nucleic acid-like substances in their interior is simply not referred to in the usual criticism.

At the conference of the New York Academy of Sciences held on May 1, 1962, during the panel discussion, Urey[16] suggested the compilation of dimensional histograms for the most simple forms of organized elements. In the systematics of lower life forms, especially among the algae, such histograms often proved to be useful in distinguishing between closely related but different species or among a single species and its varieties[17,18]. One of us[3], commenting on the remarks of Urey, pointed out that: "Morphological variations, as well as size distribution of organisms, follow a Gaussian distribution curve. 'Organized elements' follow the same pattern". (At the time of the cited conference only some preliminary results concerning a rather well-circumscribed organized element named *Apollinarisphaera meteoricola* Claus and Nagy[19] were known.) The idea of Urey has, however, been pursued and in Table 1 the numbers and measurements of the previously mentioned 303 randomly selected types 1 and 2 organized elements are given. Fig. 1 is a graphical representation of these numerical results. From Fig. 1 it is clearly evident that the types 1 and 2 organized elements according to their measurements fall into three distinct groups (three peaks of the curve). Their measurement distribution shows certain regularities, which should not be the case if they were simply to represent mineral grains. If terrestrial algal species were to be represented in the same manner as was done with the organized elements one might conclude that three possibly closely related but still distinct species are present. It is interesting to point out that according to the investigations of Palik[13], peak 1 would coincide with a microfossil she found in and described from the Orgueil meteorite and named *Chlorococcites minima* (the same species was found also by Van Landingham[14] in both the Alais and Orgueil meteorite), peak 2 would correspond to our species *Apollinarisphaera meteoricola* (*loc. cit.*), while peak 3 represents again a new species named by Palik[13] as *Apollinarisphaera ellipsoidea*. The other small peaks occurring on the graph represent obviously rarer and other somewhat more distinct forms. Here one has again to emphasize that the types of Claus and Nagy[4] do not represent systematically homogeneous populations. At the time of their publication the forms observed in the Orgueil and Ivuna meteorites were divided into five types only for the sake of convenience.

Table 1. Size Distribution of 303 Randomly Selected Types 1 and 2 Organized Elements

Group	Diameter (μ)	No.

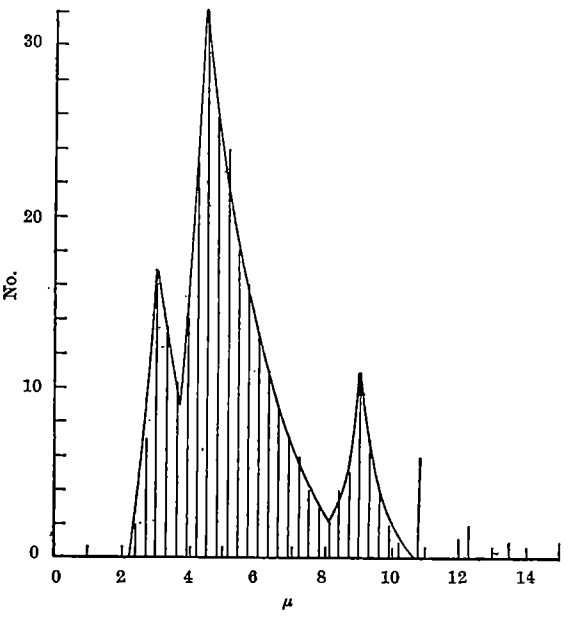

Fig. 1. Size distribution of 303 randomly selected types 1 and 2 organized elements

The dimensional histogram obtained through the careful measurements of 303 types 1 and 2 organized elements would possibly suggest that even these most simple microstructures found in Wiik's[20] four, type 1 carbonaceous chondrites do not represent just simple mineral grains as suggested by Fitch and Anders[6] or Mueller[21], but may be the remains of some kind of primitive life indigenous to the meteorites.

We thank Prof. Harold C. Urey, University of California, La Jolla, San Diego, for suggesting this work, and Dr. Urey and Dr. Bartholomew Nagy, of the same University, for their advice. We also thank Dr. A. Cavaille, Montauban, for providing the Orgueil meteorite sample.

This work was supported by the National Aeronautics and Space Administration (contract *NsG*–341).

NEARLY DIURNAL NUTATION OF THE EARTH

By Dr. R. O. VICENTE
Department of Applied Mathematics, Faculty of Sciences, Lisbon, Portugal
AND
Sir HAROLD JEFFREYS, F.R.S.
St. John's College, Cambridge

ASTRONOMICAL investigations of the theory of the rotation of the Earth round its centre of mass have always considered the theory of precession and nutation. They have approached this problem considering the Earth as a rigid body, and the last published investigations were made by Woolard[1]. The investigations of Woolard deal with the nutation in two parts, one referred to as nutation and the other as diurnal nutation. The separation of the nutation into these two parts is made because of the different axes adopted in the development of the theory.

It is well known that in the theory of the rotation of the Earth we have to consider the axes of rotation, figure and angular momentum. Woolard mentions that the positions and motions of these axes are changed by geophysical effects.

The investigations, referring to the observations and computation of the diurnal nutation, have been revived recently, and that is the reason we are dealing with it, describing its evolution in the past few years.

The theories concerned with the bodily tide of the Earth have, on the contrary, considered models of the Earth as near as possible to what we knew about the Earth's constitution, at the time they were formulated. They were not interested in the motions of precession and nutation, which are also produced by the external forces due to the actions of the Sun and Moon.

The investigations referring to the tides of the solid Earth and, on the other hand, to the shifting of the Earth's axis, originating the nutations, can be considered as a whole problem, where we consider at the same time the elastic deformations caused by the external forces (Sun and Moon) and the effects these forces have on the position of the Earth's axis of rotation.

Better knowledge about the internal constitution of the Earth, that has been gathered during the past decades, and also the known discrepancy between the observed and computed values of the constant of nutation, led to investigations which attempted to explain the discrepancy in terms of the Earth's constitution.

One of us (H. J.)[2–4] has tried to explain the difficulties encountered in the theory of nutation, using a method originally used by Poincaré[5], and taking into consideration some of the elastic properties of the shell and core of the Earth. These investigations, as has been done in the past, consider separately the case when there are no external forces (free nutations) from the case when there are external forces (forced nutations).

The earlier investigations, where the analysis is carried out in terms of displacements instead of angular velocities, show one of the features of the problem of the nutations, that is, the existence of solutions grouped in pairs near certain values. This feature of the problem was first noticed by Poincaré, and the solutions are grouped near zero and $-\omega$, where ω is the Earth's mean angular velocity with a period of a sidereal day.

The investigations, not only of the nutation but also of the bodily tide of the Earth, should be linked because both of them are different aspects of the actions of the external forces (Sun and Moon) on the Earth.

Examination of the free nutations, when there are no external forces acting on the Earth, shows a solution with a speed exactly equal to ω and another solution, near to it, but differing from it by quantities which depend on the fact that the Earth and all the layers that constitute it have a certain ellipticity. The ellipticity of the core is one of the quantities which appear in all these calculations.

We have developed a theory[6,7] that deals with both aspects of the actions of the Sun and Moon on the Earth. We adopted two Earth models, both with the same shell constitution, one called the central particle and the other called the Roche model, corresponding to two extreme cases for the constitution of the core.

We are here concerned with the free nutations, and especially nutations with periods of the order of a day. The solutions obtained for the free speeds are grouped in pairs, near zero and $-\omega$, as was expected.

The central particle model described in the paper[6] gives two pairs of solutions: 0 and $0{\cdot}00255\omega$, $-\omega$ and $-(1 + 0{\cdot}00224)\omega$. The solution zero corresponds to a statical displacement of the core without moving the shell. The solution $0{\cdot}00255\omega$ is the variation of latitude and gives the period of the Eulerian nutation. The value $-\omega$ corresponds to a constant displacement of the axis in space and, hence, relative to the Earth, in the opposite direction

to the Earth's rotation, with a period $\left(\frac{\omega}{\gamma} = 1\right)$ of a sidereal day, and is similar to the value found for a rigid body. The solution $-(1 + 0{\cdot}00224)\omega$ has a period $\frac{\omega}{\gamma} = \frac{1}{-1{\cdot}00224}$ = −23 h 56 min 47 sec sidereal time and corresponds to a nearly diurnal nutation in the opposite direction to the Earth's rotation. This last solution is not written in a convenient way in equation (22), page 159, of the aforementioned paper. But the article which one of us (R.O.V.)[8] wrote later on shows the correct solution as indicated here.

The Roche model, described in ref. 7, gives three pairs of solutions: 0 and $0{\cdot}00253\omega$, $-\omega$ and $-(1 + 0{\cdot}00403)\omega$, $-\omega$ and $-(1 - 0{\cdot}00679)\omega$. The first two pairs of solutions correspond to the central particle model, but now the solution $-(1 + 0{\cdot}00403)\omega$ has a period −23 h 54 min 13 sec sidereal time, that is, a nearly diurnal nutation with a period about 2 min shorter than the central particle model. The last pair of solutions appears because of the density structure, in the core, adopted for this model, and we have now a nearly diurnal nutation with a period −24 h 9 min 50 sec, slightly longer than a sidereal day. It is the existence of these two periods that has led to uncertainties in the calculation of the effects corresponding to semi-annual tides.

The possible explanation for all these different solutions is shown to be the motions in the core. The results obtained permit us to say that the existence of a nearly diurnal nutation is deduced from Earth models which take account of the internal constitution of the Earth, but the value of its period depends on the Earth model adopted. Because we adopted two Earth models that correspond to extreme cases of the possible behaviour of the core, we can say that the period will be between 23 h 54 min and 23 h 56 min.

The problem of the computations of the motions of the Earth's axis, with periods of the order of a day, have also been treated with more detail in a paper written by one of us (R. O. V.)[9]. It is shown that a nearly diurnal free nutation appears for Earth models with a liquid core, and this nutation differs from a sidereal day by a quantity of the order of magnitude of the ellipticity of the core.

The solutions, corresponding to the nearly diurnal nutations, have not been emphasized in the papers mentioned, because of the well-known difficulties in the detection of nutations with periods of the order of a day.

Molodensky[10], in a paper published later than the investigations already mentioned here, also solves the problem of the nutations and the bodily tides of the Earth, using two different Earth models and finding out, by numerical methods, a certain type of solution for a system of partial differential equations. The values found, for the nearly diurnal nutation, are about 3 min shorter than a sidereal day, and the difference between the two models adopted is approximately 2 sec.

Comparing Molodensky's results with the values mentioned before, and taking into consideration the different approaches used by the two theories, we can say that there are no striking disagreements in the computed values.

We wish to point out that all the solutions mentioned before are approximate, in the sense that they do not take account of all the geophysical properties of the Earth's interior, in order to be able to arrive at a mathematical solution of the equations of motion.

Several astronomical observatories have tried, in the past, to observe and compute the diurnal nutation. The observations are difficult to make because of several astronomical and geophysical causes associated with diurnal phenomena. Some of these reasons are: (*a*) Astronomical—the very small amplitudes of this nutation; variations of the refraction and aberration during 24 h, and the fact that the values of the constants of refraction and aberration are not very well known; the existence of errors in the tabulated star places that will affect observations made during a number of years. (*b*) Geophysical—the diurnal oceanic tides; motions in the Earth's atmosphere with periods of a day; the bodily tides of the Earth; deflexions of the vertical.

The detection of the diurnal nutation, from astronomical observations, is also made more difficult because what we observe is the actual shifting of the Earth's axis under the actions of the Sun and Moon, and so it includes the diurnal variations which are caused by the lunisolar component. But the values we determined before refer to the free nutation, that is, the motion of the Earth under no external forces.

It was N. Pariisky who, recently, again directed the attention of astronomers to the possibility of observing the diurnal nutation. The researches of Popov[11,12] claim to have detected a nearly diurnal nutation, based on the period of 23 h 56 min 54 sec indicated by Molodensky. Thomas[13], analysing observations made with the photographic zenith tube at Greenwich Observatory, also produces some evidence about a nearly diurnal nutation. But it points out the smallness of the amplitudes found, the large probable errors and the possibility that the observations could be well represented without taking into consideration the diurnal nutation.

The considerations made here show the complexity of the diurnal nutation. The theoretical computations, taking into account the internal constitution of the Earth, lead to the forecast of nearly diurnal nutations because of the form and structure of the core. The possibility of observing these nutations requires the utmost care in the methods adopted and the selection of the stars. The reduction of observation also needs close scrutiny.

AFTER PESTICIDES—WHAT ?*

By R. H. WRIGHT

British Columbia Research Council, University of British Columbia, Vancouver

WHEN a man accidentally touches a hot stove, he jerks his hand away instantly and without waiting to consider whether this is the proper thing to do. In the same way, his eyes blink automatically and involuntarily in response to a brilliant flash or an approaching blow. Physiologically, there is a nervous short-cut, or reflex arc, between the sensors that perceive the danger signal and the motor nerves that start the protective response. The central nervous system is largely by-passed.

It seems likely that in an insect—and particularly in a small one—limitations of space and weight will have made most of the activities reflexes of this sort: with very

* Substance of the opening address at a meeting of the Entomological Society of Ontario on September 2, 1964.

little involvement of brain and nothing that depends on what we would recognize as an intelligence. If the observed reflex behaviour seems to be intelligently and purposefully directed, this is because natural selection has long ago eliminated the inappropriate responses. The automatic nature of the reflexes becomes evident when we present the stimulus under some artificial condition so that the response is inappropriate or absurd but is nevertheless persisted in. For example, I have seen photographs of insects the abdomens of which have been cut off and whose heads continue to devour unlimited quantities of syrup which passes out through the severed end of the gut as fast as the mouth-parts take it in.

Many of these reflex activities are stimulated by chemical signals which, when they are air-borne, can be regarded as being odours or scents. There are scents by which insects locate their mates and recognize them, and other scents to make the mates receptive. Still other scents identify food supplies, oviposition sites, and, with crawling insects, the pathways to them. The nature of the olfactory process is such that a very few scent molecules can initiate a nerve impulse that sets off an amount of activity out of all proportion to the size of the original stimulus. Let me make a comparison.

The largest hydrogen bomb releases energy equivalent to 100 megatons or 10^8 tons of TNT. I do not know exactly how much chemical explosive is needed to trigger the bomb, but let us suppose it is 200 lb., or 0·1 tons of TNT. Evidently the magnification factor between the trigger and the full force of the bomb is 10^9 or 1,000 million.

Now consider the sex attractant of the American cockroach. If the reports are correct[1], 30 molecules of the pure chemical are enough to excite a male cockroach. The kinds of energy involved are difficult to determine, but let us consider the ordinary kinetic energies. Thirty molecules of the pure stuff weigh 10^{-20} g, and at room temperature their kinetic energy of translation is about 10^{-11} ergs. If the male insect weighs 2 g and is induced by the scent to run with a speed of 4 cm/sec, his kinetic energy is something more than 10^4 or ten thousand ergs. Thus the magnification factor—the disparity in energy between cause and effect—is 10^{15}, which is a million times greater than the disparity between the energy of the biggest hydrogen bomb and the trigger which sets it off.

This is why insect sex-attractant chemicals are indeed and truly the most potent biological materials known.

It is only recently that the true importance of these substances has been recognized; and their exploitation as pest control agents has still to come. One reason for this is the fact that so far they have been thought of primarily as attractants or lures. The Mediterranean fruit fly outbreak in Florida in 1956 was mapped, and control measures were monitored by means of traps baited with an artificial sex attractant[2]. Sex attractants have also been used with some success to lure insects into contact with poisons—which is obviously more economical than trying to send the poisons to the insects[3]. More recently, there have been suggestions that the sterile male technique of pest control might be effected by combining a sex attractant with a chemi-sterilant[4].

All these uses exploit one kind of property only: the ability of the chemical to draw certain insects to certain places.

The first suggestion that there might be more to the matter than this was made by M. Beroza in 1960, when he ended an article on insect attractants (in which he reviewed all their obvious applications) with one vitally important extra sentence:

> "One interesting prospect for control without the use of toxicant is the spraying of the natural sex attractant over a wide area in order to confuse males in their attempts to locate females of their species." (Ref. 5.)

What this amounts to is a suggestion that instead of using the chemical to draw an insect from *A* to *B*, the chemical should be used to prevent it from being drawn from *A* (where he is) to *B* (where she is). However, coming as it did at the end of a rather routine review article, this suggestion did not attract the attention it deserved, although it transpired later that an attempt was made in 1961 to control gypsy moths in this way[6]. Unfortunately it was a failure, apparently because the manufacturer supplied an inactive preparation the inactivity of which was not discovered until after it was all over. This summer, however, the U.S. Department of Agriculture has been repeating the experiment (with an active preparation) under the name 'Operation Confusion', but the results are not yet known[7].

No matter how that experiment turns out, I think that some, and probably many, insect species will eventually be prevented from breeding in this way. The literature contains the plainest possible hints. For example, Kettlewell writes of *Biston betularia*, the peppered moth:

> ". . . individual males can only spend a comparatively short period of time on any occasion carrying out active searching. If unsuccessful they fly off. We have tested this both in the laboratory and the field and it appears to be due to a state of fatigue which is produced by constant stimulation by scent particles." (Ref. 8.)

Again, Ignoffo says of the cabbage looper:

> "The duration of response, while the moths were continuously exposed to the strips, ranged from 2 to 5 minutes. The ability of the male to detect the attractant is lost after exposure and regained only after a 'rest' of several hours." (Ref. 9.)

Working with the same insect, Shorey described a bioassay procedure which could detect a concentration of the sex attractant equivalent to "1×10^{-4} of a female". However, he reports that there is:

> ". . . a major potential pitfall in this type of bioassay: attenuation of male responsiveness after prolonged, frequent and high-level exposure to the sex pheromone." (Ref. 10.)

The sex attractant chemicals are the most biologically potent and spectacular of the behaviour-control chemicals, but they are not the only ones. There are oviposition attractants, food scents, and, in the social insects, nest odours, all of which can in principle be used to modify the normal behaviour to the detriment of the insect and the benefit of man. Nor are the behaviour modifiers necessarily chemical.

The attraction of the moth to the flame is proverbial and taken pretty much for granted. Actually, how much do we really know about it? For example, what would the moth have done if the flame had not been there? What is the normal behaviour, and at what point did the normal behaviour change because the light was there? What was the nature of the change? Movement toward the source of the light was one effect, but there must have been other effects, and if so, what were they and how can they be turned to account? Once started, it is easy to ask the questions and to project the most interest-experiments with infra-red 'snooper-scopes' and other modern apparatus.

What I am really saying is that insect behaviour needs to be investigated from a new point of view. Behaviour has been pretty much taken to mean 'life-history' and has been investigated largely for the sake of determining the best time to apply conventional poisons or to find out whether parasites are at work, or to locate intermediate hosts the elimination of which might break the normal life-cycle. What we need to know more about now are the external agencies that tell a particular kind of insect to do a particular thing at a particular time.

Then we can give it the signal at the wrong time or place, or repeat the signal so often and so strongly that it becomes too fatigued to respond any more.

Since my main concern at the moment is with chemical agents for behaviour control, and especially with sex-attractant chemicals, I should like to look particularly at some of the problems which must be solved before they can be exploited as fully as I think they could be.

Recently, there have been some spectacular achievements in the preparation of sex attractants for several well-known insects. In Germany, Butenandt *et al.* have isolated, identified and synthesized the sex-attractant chemical of the female silkworm moth[11]. This was an enormously difficult and really excellent technical achievement, equalled only by the brilliant work of Jacobson *et al.* at the U.S. Department of Agriculture in identifying the natural sex attractant of the gypsy moth and then preparing an even more potent analogue which they call 'Gyplure'[12].

At the same time, Beroza *et al.* have been systematically exploiting another pathway to these substances and have produced highly effective lures for male medflies and a few other insects[13]. They begin by testing a wide selection of organic chemicals for signs of attractiveness. When they uncover even a hint of biological effect they have sometimes been able to build up the potency to a high level by synthesizing and testing analogues and structural variants of the active substance.

The highest possible technical virtuosity has been displayed in both approaches, and I intend no disparagement when I say that the brilliance of the work has tended to divert attention from an essential weakness. In military terms, what has been achieved is a deep penetration on a very narrow front. We now have very effective sex-attractant lures for about half a dozen insects; but we know nothing about how they act on the sensory receptors and therefore we do not know why they are effective for only one species at a time.

What is more important, the success of these workers in preparing single chemical substances which carry the whole biological effect has created an impression that in every case what must be sought is *the* sex-attractant compound. Recent writers on the subject have apparently taken it for granted that female insects can attract their mates by secreting some one, unique, attractive chemical, or just possibly a family of related chemicals each of which can be attractive all by itself.

Something that was taken for granted fifteen years ago has been largely forgotten. Thus Dethier wrote in 1947:

> "More attractive than either compound alone is a mixture of geraniol and eugenol 10 to 1 parts by volume respectively. This follows one of the most important principles relating to attractants—that mixtures are superior to any one of the component parts. The reason for this lies in the fact that attractants are odors. . . ." (Ref. 14.)

This comment is vitally important, and I should like to show why.

In the first place, it carries the implication that the mechanism by which insects perceive odours is not basically different from the mechanism by which vertebrates perceive them. From this it follows that the same underlying principles can be expected to apply in both cases. Of these principles, probably the most important for my immediate purpose is the 'information theory' developed by telephone engineers and first applied to the phenomena of olfaction by R. M. Hainer *et al.*[15].

It has been shown by Neuhaus[16], Kalmus[17], and others that each human being probably has a unique body odour which a well-trained dog can recognize. More recently, H. M. Bruce has found evidence that a female mouse can recognize the scent of her own specific mate[18], and the ability of ewes and seals to find their own offspring among thousands of others has been a source of wonder for centuries. It follows that in the vertebrates the number of discriminable smells must be virtually unlimited—a conclusion that is supported by the assertion of more than one professional perfumer that there are millions of recognizably different smells.

Now it is impossible to believe that the nose carries a specific type of receptor for each smell, and there seems to be no reason why it should. What it needs is the ability to detect a limited number of primary odours and to register mentally the differing patterns which appear when different combinations of primaries are stimulated at the same time. Information theory enables the number of separate primaries to be approximately estimated in the following way:

An odour retains its characteristic quality even when very faint, from which it follows that the sensory apparatus probably uses a binary system for coding the various primary impulses into a distinctive pattern[19]. With only one primary, and with binary coding, there can be only two 'patterns': 'there' and 'not there', or + and −. With two primaries there can be 4 patterns: + +, + −, − +, and − −; and with three there can be 8. In general:

No. of primaries:	1	2	3	4	5	....	N
No. of patterns:	2	4	8	16	32	....	2^N

If N is 20, more than a million 'on-off' patterns can be produced. There is some anatomical evidence that in the rabbit N may be 24, in which case the animal should be capable of discriminating more than 16 million odours[15]. In the vertebrates, therefore, the sense of smell has more in common with hearing than with vision. Colour perception depends on only three primaries, whereas the piano, which plays only semi-tones, has 88 keys and still reaches neither bottom nor top of the scale of audio-frequencies.

A single molecule will usually have the ability to stimulate several primary sensations depending on which primary receptor organ it is in contact with, so that the smells of compounds like vanillin or camphor are not necessarily primary. At the present time, we do not know which common odours are the primary ones because we do not know what the molecular quality is that causes a particular primary sensation to be triggered. What information theory tells us is simply this: that there is some molecular property, which we will call X, which can exist in variant forms corresponding to each of the primary odour sensations. We can call these various primary qualities X_1, X_2, X_3, X_4, X_5 . . . X_N, where N may be as high as 25 or 30.

While a dog with its highly developed olfactory sense may be able to perceive 30 primaries, in an insect it seems likely that the system is greatly simplified by reducing the number of primaries which any one species is equipped to register. The ultimate in simplification will be reached in an insect which can register only one of the primaries, say X_5. In that case, the system will have very little discrimination because it can be expected to respond to any sufficiently volatile substance the molecules of which happen to have the X_5 quality. If the number of required primaries is increased to 2, the response is a little more discriminating, and if it is as large as 5 the response will probably be quite specific with respect to a single chemical substance because it is rather unlikely that a randomly selected compound will have precisely the right combination of 5 primary olfactory qualities to activate all 5 types of receptor. It will usually be easier for a mixture of substances to do so because some of the needed qualities can be carried by one lot of molecules and the rest by another different lot.

On this basis, Dethier's comment that ". . . one of the most important principles relating to attractants [is] that mixtures are superior to any one of the component parts" makes excellent sense. It also explains both the successes and the failures of much recent work. Beroza has been

successful in producing artificial attractants for the Mediterranean fruit fly presumably because it is an insect the sensory equipment of which responds to a rather small number of primary stimuli—perhaps only 2 or 3. On the other hand, Beroza's technique of mass screening has been singularly unsuccessful in producing a gypsy moth attractant, probably because the male gypsy moth needs a very special combination of primaries to evoke a response. It so happens that this combination is embodied in a single compound which is the natural lure, but I suggest that this is unusual. Most insects probably generate an attractive scent which requires the simultaneous presence of several different molecules.

If this is so, we can see at once why the technique of mass screening has been so conspicuously successful in a small number of cases, and yet so unsuccessful generally. We can see something else too. Many people have extracted the bodies of female insects with solvents and produced crude preparations which were highly attractive to the male insects so long as they were impure, but the activity of which disappeared when an attempt was made to purify the material and isolate the attractive component from the mixture. This has commonly been taken as showing how very unstable these attractive materials are. What I suggest is that in at least some of these cases the real explanation was that several kinds of keys were needed to turn several kinds of locks simultaneously before the door would open. The idea of sex attractants as very labile substances scarcely seems to be consistent with their natural function, which is to remain intact while being carried along in the air and exposed to the destructive effects of oxygen, sunlight, water vapour, dust, and a host of minor atmospheric contaminants of the most varied kind.

It might seem, from what I have been saying, that if an attractive preparation can be made by mixing chemicals which by themselves are inactive, then we ought to be able to produce a 'universal attractant' by mixing almost any large number of substances. A mixture of 10,000 organic compounds would be expected to include all the possible combinations of primaries, and why, therefore, does it not show a general, indiscriminate attraction for all kinds of insects?

To answer this question, we must look at all the things that must happen before a smell sensation can be perceived. First, the odorous molecules must evaporate and be carried by the air into the vicinity of the sensory surface, whether it is the olfactory epithelium of a vertebrate or the antennal setæ of an insect. Secondly, the molecules must be adsorbed on to the sensory surface. Thirdly, the adsorbed molecules must interact with the sensory surface in some special and specific way so that a nerve impulse is transmitted into the interior of the animal.

Davies and Taylor[20] have derived a mathematical picture of the second and third of these stages, which suggests that the process by which the molecules become attached to the sensitive surface is quite independent of the process by which they 'puncture' it and initiate the nervous signal. In other words, it is quite possible for the sensory surface to become covered with an adsorbed layer of molecules which are not able to trigger an olfactory response themselves, and the presence of which on the surface interferes with the attachment of an odorous molecule that could trigger one. Thus a mixture which is too complex can be as biologically inactive as one that is not complex enough—though for a quite different reason.

We can, perhaps, see this actually happening in the attempts of Casida *et al.* to isolate the sex attractant of the introduced pine sawfly[21]. They made solvent extracts of female insects which in some cases showed very little biological activity until they had been given a partial purification by column chromatography. The considerable activity of their partially purified extracts usually declined on further purification. This kind of behaviour is just about what one would expect if the attractive scent is due to a mixture of substances which must all be present, and which must compete with indifferent molecules for places on the sensory surface.

I know that what I have been stating will be rather discouraging to those who had hoped that for each pest insect a specific sex attractant or other behaviour control chemical could be found and used to control its activities. If what is needed in most cases is a mixture of chemicals to provide the correct combination of primary olfactory signals, then the mass screening approach becomes extremely difficult, and the method based on isolation + identification + synthesis which is already very difficult becomes many times more so.

Nevertheless, I think we can hope to move forward in this field if we know what we are looking for. If we look for a single substance which leads the male codling moth to the female, we may be asking the right question, but more probably we are not. If we suppose that the carrot-rust fly lays its eggs alongside the carrot plant because of some single chemical emanation from the plant, we may be making a quite unwarranted assumption without even realizing it.

Karlson and Luscher have coined the word 'pheromone' for materials such as sex attractants and recognition odours which they define in this way:

> "Pheromones are defined as substances which are secreted to the outside by an individual and received by a second individual of the same species, in which they release a specific reaction, for example, a definite behaviour or a developmental process." (Ref. 22.)

This definition carries the implication to a chemist that each pheromone is a specific chemical substance. I think I have shown that this implication is likely to be incorrect, at least in so far as the pheromone is something that releases a definite behaviour in the animal that receives it.

I have chosen as my title, "After Pesticides—What?" because I believe that in the long run the use of behaviour control agents offers a better, safer, more effective, and cheaper means of pest control than is likely to be achieved by pesticides and chemi-sterilants or other inherently noxious substances. For this reason I think that research in this field needs to be greatly expanded—but it must also be properly directed. I think I have shown that the obvious things to do are not necessarily the best things to do. For example, we could waste a very large amount of money by rushing into a gigantic scheme for mass screening thousands of organic chemicals in all parts of the country or all over the World. We might do a little better by taking a smaller number of compounds and testing them in paired combinations, but even that would be a huge undertaking because 500 compounds taken at two at a time will give 250,000 pairs.

We could also spend years collecting and fractionating and bioassaying extracts and emanations from various insects in a vain attempt to isolate specific sex-attractant pheromones or other behaviour control chemicals. We would do a little better if every experiment in fractionation was followed by a bioassay of the recombined fractions; but this makes an already difficult and tedious process even more so.

In short, while the potential importance of sex attractants in practical pest control is incalculably great, there are some formidable problems to be solved before they can come into general use. My purpose has been to see what some of these problems are and to show that the obvious ways of attacking them are not necessarily the best. To attack the problem successfully and go forward quickly there is a need for new approaches to the problem and the highest type of creative thinking. Much of what I have said is speculative, but how else are we to decide what question to ask?

Long ago Darwin wrote (in a letter to A. R. Wallace):

"I am a firm believer that, without speculation there is no good or original observation."

STRUCTURE OF FILAMENTS PRODUCED BY RE-AGGREGATION OF *Salmonella* FLAGELLIN

By Dr. J. LOWY and Dr. M. W. McDONOUGH

Medical Research Council Biophysics Research Unit, King's College, 26–29 Drury Lane, London, W.C.2, and Guinness-Lister Research Unit, Lister Institute of Preventive Medicine, Chelsea Bridge Road, London, S.W.1

FLAGELLA are the contractile organelles responsible for locomotion in bacteria. They exist as long filaments (up to about 10μ) of a uniform width (diameter 100–200 Å depending on the species) and helical shape which in electron micrographs is distorted into a sinusoidal wave form. Our experiments were performed with *Salmonella typhimurium*, where the wave-length of the flagella is about 2·5μ (ref. 1). Work from a number of laboratories has so far led to the identification of only one kind of protein (flagellin) in these structures; the molecular weight of the flagellin of *S. typhimurium* has been estimated from physical measurements as 40,000 (McDonough, unpublished results), in agreement with Weibull[2] for *Proteus vulgaris* and by Abram and Koffler[3] for *Bacillus pumilus* flagellins.

Recent investigations with the electron microscope using negatively stained preparations of several species of bacteria have shown that flagella, still attached to the cell body, can exist in two structural forms[4,5]. Structure *A* consists of regularly spaced globules which appear alike and are roughly spherical in shape (Fig. 1*a*). The diameter of these globular units as estimated by their spacing is about 50 Å and this is consistent with the view that each is a molecule of flagellin. The molecules are aligned in longitudinal rows and alternate with each other in adjacent rows (Fig. 1*a* and *b*). They are helically arranged so that the number per turn of each helix equals the number of longitudinal rows. In the model proposed[4,5] (Fig. 1*b*) this number is 8 for *S. typhimurium*, the pitch of the helix is about 200 Å, and there are about 4,000 molecules per wave-length (2·5μ) of the flagellum.

Structure *B* does not show globules or helices but an alternating sequence of long regions of continuous lines and short regions where the continuity of the lines is interrupted; the number of lines is the same as the number of rows of globules in the *A* structure[4,5]. In *Pseudomonas rhodos* both structures *A* and *B* can be seen in different parts of the same flagellum[5]. Only the *A* structure has so far been observed in *S. typhimurium* strain *SW* 1061 (ref. 5), a mutant of strain *LT* 2 which is monophasic for the phase-2 antigen 1,2 (ref. 6). Here we describe the structures seen when molecules of flagellin prepared from the flagella of this organism are allowed to aggregate *in vitro*. As reported by Ada, Nossal, Pye and Abbot[7] for *Salmonella adelaide* flagellin and by Abram and Koffler[3] for *Bacillus pumilus* flagellin, such re-aggregation may result in the appearance of long, sinusoidal filaments with

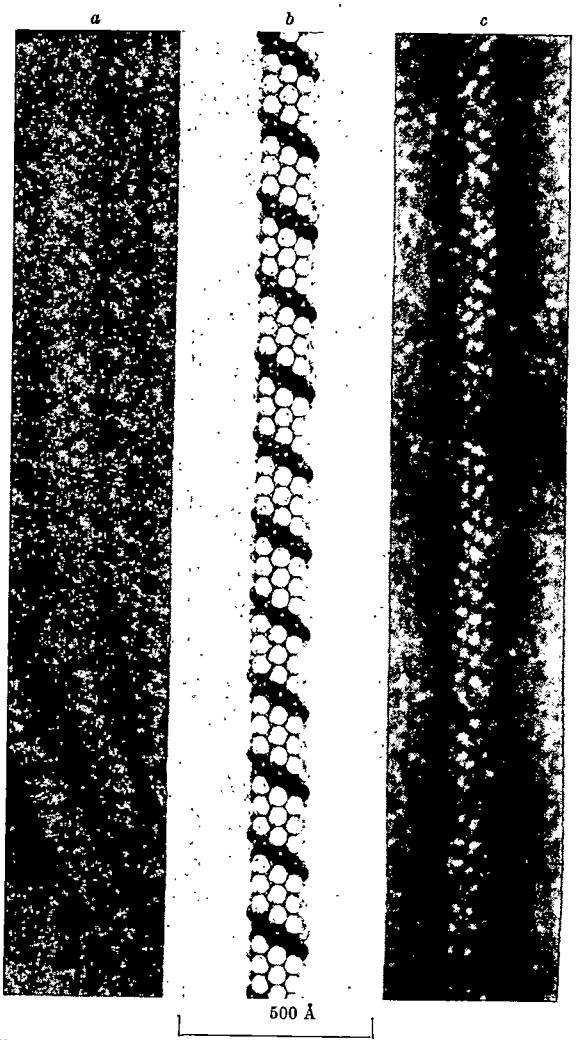

Fig. 1. *a*, *Salmonella typhimurium*, electron micrograph of flagella showing *A* structure (negatively stained with uranyl acetate); *b*, model showing possible arrangement of the molecules in the *A* structure (the spheres represent molecules and their helical organization has been indicated by showing some of them in black); *c*, electron micrograph of part of a filament prepared from flagellin of *S. typhimurium* (negatively stained with uranyl acetate)

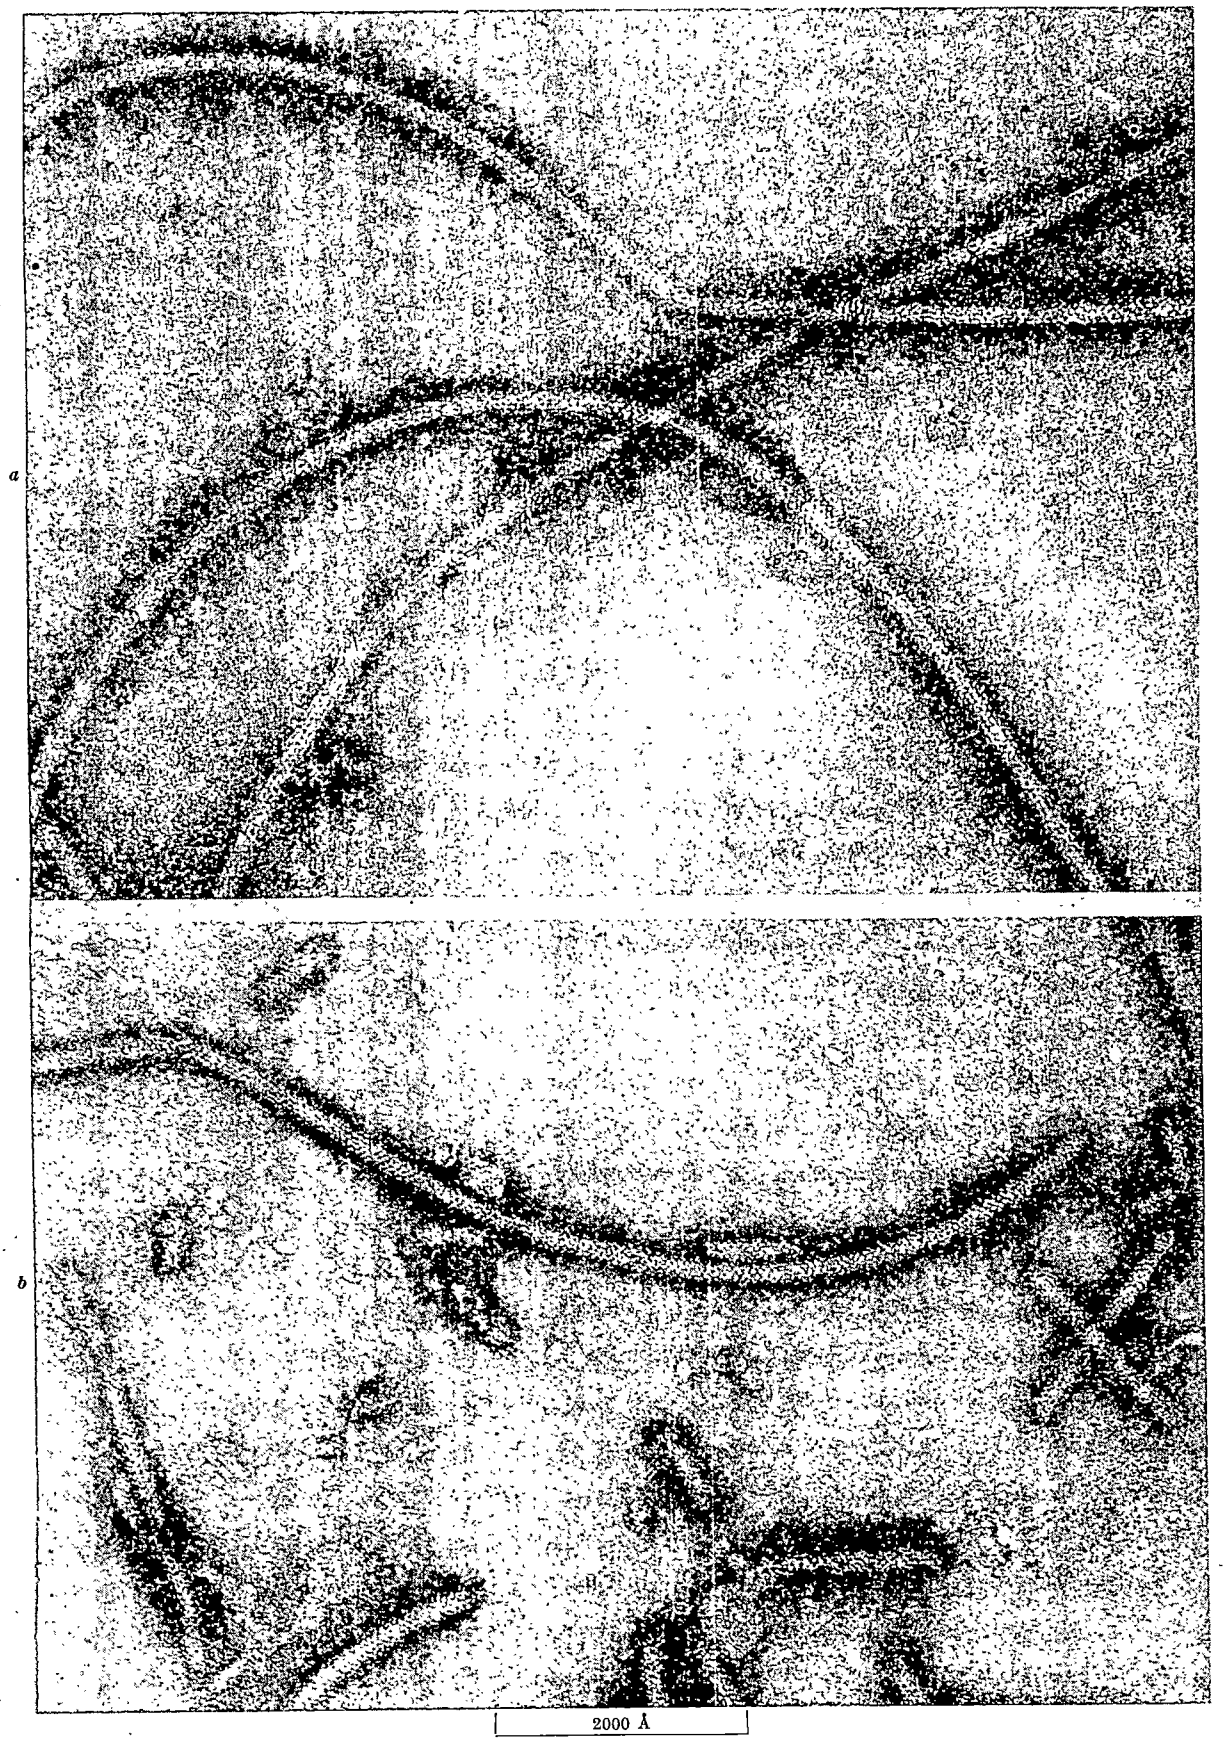

Fig. 2. *a*, *Salmonella typhimurium*, electron micrograph of flagella showing *A* structure (negatively stained with uranyl acetate); *b*, electron micrograph showing filaments prepared from flagellin of this organism and stained by the same method

a width comparable to that of the native flagella. The fine structure of the filaments was not described.

Flagellin was prepared as follows. The bacteria were deflagellated in a blender, and the cells removed by centrifugation. The flagella which remained in the supernatant were concentrated and purified by alternate fast (105,000*g* for 1 h) and slow (20,000*g* for 5 min) centrifugation, and then dissociated into monomeric flagellin by adjusting the *p*H to 2·0 with N hydrochloric acid[2]. Insoluble material was removed by centrifugation at 105,000*g* for 1 h. The remaining material in the supernatant which contained the flagellin was adjusted to *p*H 7·0 with 0·1 N sodium hydroxide and then brought to 70 per cent saturation with ammonium sulphate. The flocculent white precipitate was spun down, suspended in distilled water and then dialysed against several changes of distilled water at 4° C. The suspension, which was now opalescent and somewhat viscous, was centrifuged at 105,000*g* for 1 h and a large, clear, gelatinous pellet was obtained.

Small portions of this material were suspended in distilled water and prepared for examination in the electron microscope by the negative contrast method of Huxley and Zubay[8]. The microscope was a Philips 200 (80 kV, double condenser, 20μ objective aperture).

Much of the flagellin material thus prepared consisted of short structures of filamentous form up to about 2000 Å long; many curved filaments (several thousand Å in length) were also present (Fig. 2*b*). Occasionally filaments several microns in length and looking like sine waves were seen. All the re-aggregated structures show regularly arranged globules which are lined up both longitudinally and obliquely with respect to the long axis (Fig. 1*c*). Either 4 or 5 longitudinal rows can be seen (Fig. 2*b*) and their lateral separation was found to be about 41 Å (20 measurements, ranging from 38 Å to 46 Å). The axial separation of the globules was about 50 Å (26 measurements, ranging from 46 Å to 54 Å). In all these respects the structure of the flagellin filaments very closely resembles that of *A* structure flagella attached to the bacterium (cf. Fig. 1*a* and *c*, Fig. 2*a* and *b*), where the corresponding results were 37 Å (17 measurements, ranging from 29 Å to 40 Å) and 51 Å (38 measurements, ranging from 48 Å to 55 Å). Furthermore, as in negatively stained preparations of *A* structure flagella[4,5], there was no indication of a hollow centre in the flagellin filaments.

We conclude that flagellin molecules can 'self assemble' into curved filaments, presumably helical, which have a fine structure indistinguishable in the electron microscope from that of the original flagella. Perhaps the most interesting problem now is to find whether flagellin filaments can be made to contract or if, as in muscle, this process requires the presence of two protein components.

We thank Sir John Randall and Prof. B. A. D. Stocker for their encouragement and provision of facilities, and Mr. Z. Gabor for assistance with the photography. This work was supported in part by a research grant (*AM* 06166-01) from the Institute of Arthritis and Metabolic Diseases, U.S. Public Health Service.

NEWS and VIEWS

Director of the Royal Aircraft Establishment: Sir Robert Cockburn, K.B.E., C.B.

Sir Robert Cockburn, chief scientist of the Ministry of Aviation, has been appointed director of the Royal Aircraft Establishment, Farnborough, in succession to Dr. M. J. Lighthill, who is taking up a Royal Society research professorship (*Nature*, 202, 134; 1964). Sir Robert Cockburn took up his new appointment on October 1, 1964. Sir Robert has been chief scientist of the Ministry of Aviation since its formation five years ago (*Nature*, 184, 938; 1959). He was born at Portsmouth in 1909 and educated at the Portsmouth Secondary School and Portsmouth Municipal College. He entered the Scientific Civil Service in 1937 and served at the Royal Aircraft Establishment, at the Air Ministry Research Establishment at Worth Matravers and later at the Telecommunications Research Establishment (now Royal Radar Establishment), Malvern. On promotion to senior principal scientific officer in January 1946 he was appointed deputy head of the Nuclear Physics Division at the Atomic Energy Research Establishment, Harwell. He was seconded to the Air Ministry as a scientific adviser, with the grade of chief scientific officer, in September 1948, and on return to this department in January 1954 was appointed principal director of scientific research (guided weapons and electronics). In June 1955 he was appointed deputy controller of electronics and in October 1956 became controller of guided weapons and electronics and three years later was appointed chief scientist.

Physics in the University of Warwick : Prof. A. J. Forty

Dr. A. J. Forty, whose appointment to the chair of physics in the University of Warwick has recently been announced, was educated at the University of Bristol. He took his B.Sc. there, and stayed to work for his Ph.D. under Prof. F. C. Frank. His work was on the mechanism of crystal growth, and the paper by Forty and Frank on the growth of cadmium iodide crystals, showing spiral growth steps associated with screw dislocations, is now a classic. After service in the Royal Air Force, Forty joined the research laboratories of Tube Investments, where he worked for several years. He then returned to Bristol, where he has been directing an active research group investigating the mechanical properties of solids. This research has been on several fronts; notably the direct examination of the atomic processes of damage to crystals by electron bombardment in an electron microscope; the investigation of the physical processes governing stress corrosion; examination of the mechanism of cleavage and fracture of crystals; and the use of ultra-violet microscopy. An interesting by-product of the damage investigations, which may have practical application, has been the observation that lead iodide at high temperatures is capable of forming a photographic image of high definition. Dr. Forty combines a flair for applying fundamental physics to problems of technological interest with an ability to organize fruitful research programmes. His appointment to a new university in a highly industrial region is most fitting.

Physical Chemistry in the University of Strathclyde: Prof. Manfred Gordon

Dr. Manfred Gordon, who has been appointed to the chair of physical chemistry, recently created in the University of Strathclyde, Glasgow (*Nature*, 203, 125; 1964), graduated in the University of London in 1940, and afterwards was awarded the degrees of M.Sc., Ph.D. and D.Sc. of that University. He has had a wide and varied experience in departments of (pure) chemistry, technical chemistry and textile chemistry in the three

institutions which have now been designated as 'SISTERS'. His previous posts include those of senior physical chemist in the Dunlop Rubber Organization, lecturer in high-polymer chemistry at the Royal College of Science and Technology, Glasgow (now the University of Strathclyde), Courtauld Fellow at the Manchester College of Science and Technology, assistant director at the Arthur D. Little Research Institute, Inveresk, and finally reader in physical chemistry at the Imperial College of Science and Technology. He is the author of more than fifty publications, largely in the physical and statistical aspects of polymer science, a subject in which he has deservedly earned an international reputation, and is the author of a text-book on high polymers. His long and varied experience in the industrial sphere, together with his keen interest in bridging the gap between basic science and technology, will be an invaluable asset to the University.

Medical Research Council: New Research Units and Groups

The Medical Research Council is to establish the following two new research units and three new research groups: *The Microbial Systematics Research Unit* will be set up at the University of Leicester under the direction of Dr. P. H. A. Sneath. The Unit will be engaged in research on the classification of micro-organisms, with special reference to numerical taxonomy and computer methods. *The Mineral Metabolism Research Unit*. On the retirement of Prof. L. N. Pyrah as director of the Metabolic Disturbances in Surgery Research Unit in the University of Leeds, Dr. B. E. C. Nordin will become director of the Unit, which will be renamed. The Unit will be mainly engaged in research into the causes of renal stone, the dietary requirement of calcium and the metabolism of bone-seeking isotopes. *The Research Group in Applied Neurobiology* will be established at the Institute of Neurology, University of London, under the honorary direction of Dr. J. B. Cavanagh. The Group will be concerned with investigations of cellular relationships in the peripheral and central nervous system. *The Research Group in Clinical Respiratory Physiology* is being set up at the Postgraduate Medical School, University of London, under the honorary direction of Dr. J. B. West. The Group will investigate the physiological mechanisms controlling the distribution of air and blood in the lungs in health and disease. *The Research Group in Medical Demography* is to be established in the Department of Medical Statistics and Epidemiology at the London School of Hygiene and Tropical Medicine, under the honorary direction of Mr. W. Brass. The Group will undertake research into the effects of changes in population size and structure on the occurrence of disease and, conversely, of the effects of developments in medicine on population characteristics.

The Metabolic Reactions Research Unit

The Council's plans to establish a Metabolic Reactions Research Unit under the honorary direction of Prof. E. B. Chain were announced in June 1963 (*Nature*, 198, 1252; 1963). The Unit, which now has been set up in the Department of Biochemistry at the Imperial College of Science and Technology, London, will undertake research into the problems of metabolic reactions in the tissues of higher animals, including man, and in micro-organisms.

U.S. National Academy of Sciences and the National Research Council

Organization and Members 1963–64 includes full lists of members of the U.S. National Academy of Sciences and of the National Research Council (Pp. 143. Washington, D.C.: National Academy of Sciences–National Research Council, 1964). Details are also given of the membership of the various committees and boards and of the divisions and offices with their officers and committees. There is an introductory note outlining the organization and objectives of the Academy and the Research Council, and the functions of the various committees are shown under the appropriate headings. There is an index of names.

Development and Research in the Furniture Industry

The fifteenth annual report of the Furniture Development Council, covering the year ended December 31, 1963, notes a steady increase in the demand for method study consultancy services, and the scope of the activities of this department has widened. The Council's Product Costing System has been installed or revised by the Council's cost consultants at 20 different firms during the year, and a report, *Production Control in the Furniture Industry*, is being published shortly, while one on *Furniture Factory Planning and Layout* is in preparation. A list of papers issued by the Council and the Furniture Industry Research Association, 1949–63, is appended. On July 6, 1964, the Furniture Industry Development Council (Amendment No. 2) Order, 1964, was approved in the House of Lords. The research activities of the Furniture Development Council were taken over by the Furniture Industry Research Association on its establishment in 1961, and the Association receives most of its industrial income through the Council from the levy authorized by the Furniture Industry Development Council (Amendment) Order, 1958. As Lord Drumalbyn explained in moving the approval of the Order, the Council itself provides many services to the industry, including method study and costing, statistical and economic services, and the study of design and marketing, some of which are self-supporting, but the purpose of the order is to provide additional funds to enable the Research Association to expand and maintain its programme of research. The Order raises the amount of the levy which may be imposed on the industry by the Furniture Development Council to a maximum of £75,000 a year, and the proposed increase is supported by the British Furniture Manufacturers' Federated Associations and the National Federation of Furniture Trade Unions.

The Natural Rubber Producers' Research Association

The research programme of the Natural Rubber Producers' Research Association, under the direction of Dr. L. Mullins, continues its fundamental investigations of the science and technology of natural rubber and related materials. The problem of the chemical constitution of natural rubber vulcanizates is, after many decades of hypothesizing, showing signs of yielding its secrets under the combined attack of chemists, physicists and technologists. One of the methods developed for establishing the identity of sulphur-containing cross-links in vulcanizates has been the use of 'chemical probes', and a recent publication of the Association (Publication No. 473, by C. G. Moore and B. R. Trego) deals with the rearrangement of alkenyl groups that occurs during the desulphuration of model organic trisulphides by the probe triphenylphosphine. On the biochemical side, the biosynthesis of natural rubber continues to be investigated, and experimental evidence has recently been obtained (Publication No. 479, by B. L. Archer, B. G. Audley, E. G. Cockbain and G. P. McSweeney) that mevalonic acid is converted into isopentenyl pyrophosphate in the aqueous phase of *Hevea brasiliensis* latex through the intermediate formation of mevalonate phosphates. Subsequent incorporation of isopentenyl pyrophosphate into the growing rubber molecule is believed to occur at the surface of the rubber particle and to involve the attachment of isopentenyl pyrophosphate at an allylic pyrophosphate group situated terminally in the rubber molecule. Three distinct aspects of the physics of natural rubber—namely, friction, reinforcement and foam elasticity—have been investigated and these typify the Association's concern with fundamental aspects arising out of the use of rubber. A theory of dynamic rubber friction (Publication No. 477,

by A. Schallamach) has been developed in terms of the number and average life-time of the bonds due to molecular adhesion being dependent on the velocity and temperature of the rubbing members. The enhanced strength properties of reinforced rubbers are shown to result from the effects of rubber hysteresis in reducing the stress at the tip of the growing crack (Publication No. 475, by E. H. Andrews), and the effect of filler particles is illustrated by electron microscope photographs. The deformation properties of foamed elastic materials are discussed (Publication No. 478, by A. N. Gent and A. G. Thomas) in terms of a model consisting of a three-dimensional network of thin threads. The theory is extended to open-cell foams by considering the viscous damping due to the flow of air through such a network.

Mineral Deficiencies in Rubber Cultivation

AGRICULTURAL science owes much to an understanding of signs displayed by the plants themselves and by the leaves in particular. In the sphere of rubber cultivation, as in so many others, painstaking pot culture and field experimentation have been rewarded by a knowledge of the mineral shortages linked with given leaf symptoms. A recently published monograph from Kynoch Press, entitled *Mineral Deficiencies in Hevea and Associated Cover Plants*, contains excellent reproductions, from colour photographs, of leaves affected by deficiencies of the essential major and minor nutrient elements (By Victor M. Shorrocks. Pp. viii+76 (53 plates). Kuala Lumpur: Rubber Research Institute of Malaya, 1964. 25 Malayan dollars). Research on the soil, that "frugal custodian of plant nutrients", to quote the author's own description, has been prosecuted by the Rubber Research Institute of Malaya since the late 1920's, and this publication, nourished on earlier work which resulted in the compilation of Bolle-Jones, shows a healthy response indeed. Alongside symptoms found in *Hevea brasiliensis* are set those in three commonly found leguminous ground cover plants, *Pueraria phaseoloides*, *Centrosema pubescens* and *Calopogonium mucunoides*, thus enabling the grower to turn these species to a new advantage as 'indicator' plants. Descriptions of deficiency symptoms and of their occurrence, not overlooking waterlogging symptoms, albeit strictly applicable to Malaysian conditions only, will be of value to workers in many other rubber-growing areas, as will the introductory section on plant nutrients to those studying different crops. Tables of published data are given on the results of leaf analysis, a technique which the author himself has used to no mean effect. To achieve successful corrective fertilizer application it will surely be essential to follow the advice given here. At the present time, known deficiencies in Malayan rubber trees include magnesium, potassium, calcium, nitrogen, phosphorus and manganese. We may look forward to progress, say, on such topics as yields and their relation to minor elements, and this timely publication marks an important stage in a field having world-wide economic implications.

Laminated Timber Structures

MODERN gluing techniques have rendered possible the use of laminated wood in timber structures of almost any size and shape. This form of construction is now apparently finding favour with architects concerned with certain types of building such as churches, schools, recreation halls, social centres, restaurants and, where practicable, industrial buildings. Laminated timber permits of combined structural strength and attractive design. Glued timber structures are free from corrosion hazards; thus maintenance costs are greatly reduced or even eliminated. A recent issue of *Technical Notes 258* (CIBA (A.R.L.), Ltd., Duxford, Cambridge, June 1964) is devoted entirely to "Timber Structures by Muirhead and Sons, Ltd.". Details and illustrations of several examples of laminated work incorporating 'Aerodux' resorcinol adhesive (made and supplied by CIBA) are given. These include a framework for a sports building at Newcastle upon Tyne, circular in shape, with an overall diameter of 206 ft.; a sports hall at Grangemouth with laminated timber portal frames spanning 35 ft.; the Church of the Holy Rood, Grangemouth, with laminated gothic arches with a span of 45 ft.; showrooms for the South of Scotland Electricity Board at Airdrie, in which very extensive use was made of laminated timber work incorporating 'Aerodux 185' adhesive; a cattle court in East Lothian having laminated portal frames spanning about 60 ft. The applications of laminated woodwork structures as described in this pamphlet are certainly impressive, but whether in the long run this type of timber construction ". . . is able to offer serious competition with steel and reinforced concrete", for example in the tower-block type of buildings now so conspicuous in London and elsewhere, likewise in modern school and factory designs, must, for many obvious reasons, remain a moot point.

Architecture of the Oviduct of the Domestic Hen

IN response to the article with the above title, which appeared on p. 699 of the August 15 issue of *Nature*, Prof. G. M. Wyburn has written to the Editor, pointing out that probably the most comprehensive histological investigation of the hen oviduct was carried out by Dr. K. Richardson in 1935. The work was undertaken in the Anatomy Department, University College, London, when Dr. Richardson was investigating the secretory phenomena in the oviduct of the fowl, including the process of shell formation, by means of the micro-incineration technique (*Phil. Trans.*, B, 225, 149; 1935). These investigations have recently been extended by electron microscope surveys in the Anatomy Department of the University of Glasgow. One of these, by Drs. R. M. C. Aitken and H. S. Johnston, was concerned with the fine structure of the infundibulum of the avian duct (*J. Anat. London*, 97; 1963). It showed that cells of the infundibular glands differ in certain respects from those of the succeeding albumen-secreting region and may be of greater significance in chalaza production than heretofore supposed and not simply additional albumen-secreting glands; although it is probable that these represent particular functional states of the same cell, this has not yet been confirmed. Ciliated non-secretory, ciliate secretory and non-ciliated secretory cells were distinguished in the surface epithelium, and the possibility of transformation from one type to another was suggested. The cilia present distinctive features, the apparent cross-striation of the rootlet in this species being due to its ensheathment by a fibre arranged as a helix. The structure is therefore reminiscent of the spermatozoon. Further investigations have been made by Drs. Johnston and Aitken and Prof. G. M. Wyburn into the fine structure of the avian uterus (*J. Anat. London*, 97, 3; 1963). This has revealed that the apical and basal cells show marked differences in their fine structure. Their significance in relation to the formation of the shell matrix and cuticle was also examined. The distinctive features of the junctional zone glands of the uterus were described, including the types of secretory granule. The uterine gland cells have secretory granules within vacuoles, and changes in the microvilli of these cells are possibly related to the passage of calcium ions during calcification of the organic matrix of the shell. Two types of dense cytoplasmic body have been demonstrated in the cytoplasm of the uterine gland cell. There is some evidence to support the view that the granular bodies, which may be lysosomes, are derived from mitochondria.

Spectrochemical Analysis of Soils, Plants and Related Materials

IT is about forty years since attention was first directed to the importance of minute amounts of certain elements in the healthy growth of plants and animals. Boron and then manganese and cobalt, followed by copper, zinc and

molybdenum, were proved to be essential 'minor' elements, but progress in this field of investigation was rather slow and uncertain until techniques were developed to deal adequately with the measurement of quantities of the order of a few parts per million and at the same time to overcome the difficulties associated with contamination. Our ideas on 'purity' have been completely altered by innovations in micro-analytical technique such that the classical chemical methods have been largely replaced by the use of equipment that enables the analyst to carry through large numbers of determinations in a short time. Flame emission and arc methods of spectrographic analysis rapidly achieved a precision and reliability under the lead of R. L. Mitchell, and in 1948 he wrote *Technical Communication* No. 44 of the Commonwealth Bureau of Soils, which was a review of the literature on spectrographic analysis relevant to soils, plants and related substances, with details of the methods devised at the Macaulay Institute. This was reprinted in 1956 and now, because of continuing demand, and major advances in methods, it has been brought up to date by the provision of an addendum and appropriate bibliography occupying 37 pages (*Technical Communication* No. 44*A*, *The Spectrochemical Analysis of Soils, Plants and Related Materials (with Addendum)*. Pp. ix+225. Farnham Royal, Bucks: Commonwealth Agricultural Bureaux, 1964. 40*s*.; 6 dollars). The original text is still relevant and is reprinted unaltered. The introduction of direct-reading instruments, with "the change in emphasis" from photographic to photoelectric assessment of the spectral line intensity, "has prompted" the change in title from spectrographic to spectrochemical analysis. Some idea of the nature of the modifications of the original methods and the development of new ones may be gained from the headings of the main sections of the addendum: the measurement of the photographic plate, direct current arc excitation, porous cup solution spark excitation, spark and interrupted arc excitation, flame photometry, atomic absorption, pretreatment of soils and plant materials, application to soil and plant investigations. The book also includes a brief description of special facilities for trace element work in the new Spectrochemistry Department of the Macaulay Institute.

Soil Survey of Great Britain

The aim of the Agricultural Research Council Soil Survey of Great Britain is to provide a record of the soils of the country, in the form of maps and memoirs, from field observations and laboratory analyses, designed to establish the derivation of the soil as well as its characteristics and distribution. The printed records are of the greatest value to those concerned with agriculture or with drainage, ecology, geography or land-use. The sixteenth report (Pp. vi+39. H.M.S.O., 1964. 5*s*.) describes the work done in 1963; two maps show those areas of the country where field work has been completed or is in progress. For example, soil maps were published in 1963 of the districts around Cambridge and around Church Stretton, while a further nine sheets are in the press; memoirs for the district around the Menai Straits, and the area around Aberdeen, Inverurie and Fraserburgh have been published, and another is in the press. Several other memoirs to accompany maps are in preparation. There are brief accounts of the general pattern of the soils being mapped in various parts of Britain, of the special surveys made for such bodies as the Nature Conservancy, the National Agricultural Advisory Service, the Forestry Commission, and for various drainage authorities, and of the advice and assistance given to a wide range of enquirers. There is also a list of the contributions to scientific journals by members of the Survey staff.

International Lactic Acid Prize

Stichting Ilra, International Research Association, 39 Overgaden neden Vandet, Copenhagen *K*, is offering two prizes, valued at 1,500 and 750 U.S. dollars, for the two best essays received on "The Position of Lactic Acid and its Derivatives in the Nutrition and the Metabolism of Ruminants". Entries will be assessed by an international committee of adjudicators selected by 'BIOCENTRALEN'—the Danish Society of Biotechnical Industry and Research. All papers entered for these prizes should be submitted in English, French or German to BIOCENTRALEN, Bülowsvej 13, Copenhagen *V*, not later than November 1, 1965.

Perkin Centenary Trust: Awards

Perkin Centenary scholarships for 1964 have been awarded to Mr. D. Harris, of Heaton Moor, Cheshire, tenable at the Royal College of Advanced Technology, Salford; to Mr. T. A. Moran, of Illingworth, Yorkshire, tenable at the Bradford Institute of Technology; and to Mr. J. A. Scott, of Burneside, Westmorland, tenable at the Royal College of Advanced Technology, Salford.

Financing Medical Research

The Office of Health Economics has issued the following correction concerning the medical research expenditures of two charities which were referred to in their report *The Finance of Medical Research* (*Nature*, 203, 999; 1964). The total grants made by the Nuffield Foundation for medicine in 1961–62 amounted to £669,000, of which only £245,000 were for buildings. The Leverhulme Trust do not finance buildings at all from their funds, but do make grants for the conduct of medical research. The estimated total amount granted or allocated for the conduct of research in Britain by all trusts supporting medical research therefore amounted to approximately £790,000 in 1961. The total from all private sources was about £2·5 million, in addition to £1·4 million for buildings. The estimated total of capital and current expenditures on medical research from all sources in Britain in 1961–62 remains as £27 million.

Announcements

The seventh British weed control conference, organized by the British Weed Control Council, will be held in Brighton during November 23–26. Further information can be obtained from Mr. W. F. P. Bishop, 140 Bensham Lane, Thornton Heath, Surrey.

A conference on "Magnetism and Magnetic Materials" will be held in Minneapolis, Minnesota, during November 16–19. Further information can be obtained from J. T. Elder, Minnesota Mining and Manufacturing Co., 400 McKnight Road, St. Paul, Minnesota 55119.

A symposium on "Mammalian Radiobiology at the Cellular Level", arranged by the British Institute of Radiology, will be held at the Institute on November 20. Further information can be obtained from the General Secretary, British Institute of Radiology, 32 Welbeck Street, London, W.1.

The effects on human beings of additives, colouring matter and foreign substances in foodstuffs will be the subject of an international conference to be held in Brno during November 19–21. Further information can be obtained from Dr. M. Totová, Katedra hygieny University J. E. Purkyně, třída Obr ánců miru 10, Brno.

A meeting of the Welsh Soils Discussion Group on "Chemical Means on Assessment of Soil Fertility" will be held at the Welsh Plant Breeding Station, Plas Gogerddan, on November 25. Further information can be obtained from Dr. A. H. Charles, Welsh Plant Breeding Station, Plas Gogerddan, near Aberystwyth.

OXIDASES AND RELATED OXIDATION-REDUCTION SYSTEMS

AN international symposium on oxidases and related oxidation-reduction systems was held at Amherst College, Amherst, Massachusetts, during July 15–19. The organizers of the symposium (T. E. King, H. S. Mason and M. Morrison) made use of the presence of many biochemists in the United States for the sixth International Congress of Biochemistry, which was held in New York at the end of the month, to bring together most of the leading workers in the field. The symposium was restricted to 49 participants, all of whom except two presented papers. The geographical distribution of the speakers was: United States, 28; Japan, 5; United Kingdom, 4; Sweden, 3; Australia, 2; Israel, 1; Switzerland, 1; Germany 1; The Netherlands, 1. The symposium was generously supported by grants from the National Institutes of Health and the Office of Naval Research. The organizers were assisted by an advisory committee consisting of B. Chance, P. George, M. D. Kamen and E. C. Slater.

The first session of the symposium, on fundamental chemistry, was opened by P. George, who took as his theme the "Fitness of Oxygen" (cf. Lawrence J. Henderson's *The Fitness of the Environment*, first edition, Macmillan, New York, 1913; Beacon Paperback, Boston, 1958) as a terminal oxidant. N. Sutin discussed the mechanisms of some electron transfer reactions in solutions. F. W. Cope proposed a new kinetic theory of electron and ion transport, based on electron conduction within semiconductive particulate and membranous solid structures. His claim that the application of solid-state physics to enzyme kinetics is more fruitful than the conventional theories based on the 'law of mass action' was rather strongly attacked both by Sutin and by Chance. In general, it appeared that the biochemist is not ready to abandon the conventional approach for one that does not seem to offer any advantages, and which, according to B. Rosenberg's paper on some problems in the electrical conductivity of proteins, appears at present to have very limited experimental support.

The second session on peroxidase–oxidases, model oxidases, and related systems was opened by a theoretical investigation of the structure of oxygen–metallic ion complexes by L. L. Ingraham. His molecular-orbital calculations supporting a $Fe^{3+}.O_2^-$ structure for oxyhæmoglobin were vigorously discussed, especially by Sutin and L. Orgel. Organic chemistry was now brought into the picture by R. O. C. Norman speaking on the mechanisms of aromatic hydroxylation and ring-opening reactions, and by W. S. Caughey on structure and medium effects on the reactions of iron(II) porphyrins with oxygen and carbon monoxide. M. E. Winfield presented a mechanism for the autoxidation of myoglobin and proposed the first of many mechanisms brought forward during the symposium on cytochrome oxidase. I. Yamazaka suggested a mechanism of the reaction in which peroxidase acts as an oxidase. W. E. Knox described his experiments on the activation of tryptophan pyrrolase by reduction and by hæmatin.

The third session was devoted to oxidases containing non-hæm iron or copper (with the exception of cytochrome *c* oxidase). D. I. Crandall discussed molecular oxygenation by iron-activated oxygenases. O. Hayaishi confined his attention to comparative investigations on pyrocatechase and metopyrocatechase, reserving the more general aspects of oxygenases for a brilliant exposition at the opening session of the International Congress of Biochemistry later in the month. Investigations on copper oxidases were opened by Bo G. Malmström, who discussed the two forms of copper which he has shown to be present in these oxidases by determination of the electron-spin resonance spectrum. E. Frieden reported on the catalytic activity of ceruloplasmin and its inhibition, and C. R. Dawson concluded the session, but not the discussion on copper, by his paper on the reaction between copper and the apoenzyme of ascorbate oxidase.

The chemists had the first word in the fourth session on flavin-containing oxidases. P. Hemmerich discussed the chemistry of flavin–metal interaction, dealing in particular with metal–ligand charge transfer, and A. Ehrenberg, the nature of flavin-free radicals. The biochemists continued with discussions by T. P. Singer on the comparative biochemistry of succinate dehydrogenase, by Y. Ogura on the action of mechanism of several flavin enzymes, by V. Massey on D-amino-acid oxidase, by R. C. Bray on xanthine oxidase, and by P. Handler on several metalloflavoproteins. The controversy which has raged for several years on whether the iron atom in iron-containing flavoproteins undergoes oxidoreduction in the course of the enzymatic reaction was not settled, even after an extra evening session. H. Beinert produced new and convincing evidence that iron is concerned in the $g = 1{\cdot}94$ signal in the electron-spin resonance spectrum which appears on reduction of these flavoproteins. This does not, however, prove that the iron atom is reduced, since the signal probably involves another atom, possibly a sulphur. V. Massey made a plea that his data, which show that the rate of reduction of the iron atom, as measured chemically, is several orders of magnitude slower than the overall reaction catalysed by the enzyme, should not be ignored.

M. D. Kamen opened the fifth session with a discussion on the status of the *Rhodospirillum* hæmoprotein and other atypical hæmoproteins as bacterial oxidases. I. C. Gunsalus considered the generation of active oxygen for mixed function oxidation, dealing in particular with investigations arising out of his discovery that this reaction is involved in the lactonization of camphor. Microsom[al] oxidases were discussed in four papers: by Hj. Staud[inger] on the mechanism of microsomal hydroxylation [with] Estabrook on spectral and kinetic investig[ations] microsomal pigments involved in this reacti[on] on the CO-binding hæmoprotein and NA[DPH] flavoprotein in liver microsomes and their [role] somal electron transfer, and H. S. Mason [on] and oxidase function of liver microsome[s].

A 'free' afternoon was devoted to a [discussion] controversial question of the separat[ion] chrome *a* and a_3. Most workers in t[his field] to accept the postulate of Keilin and [Hartree] made in 1939, that cytochrome *c* [is] differently bound hæm *a* molecules [which] with oxygen and respiratory inh[ibitor] does not. However, the so-calle[d] still supported by Onunuki and [Smith] assume that a single protein co[mplex] prosthetic groups (Siamese tw[ins]) a concept which can be formul[ated] is at present no compelling [evidence] separate proteins—cytochrom[e] although this cannot yet be ex[cluded].

Ten papers on cytochrome c[oxidase] the next two sessions, by K. [Okunuki] Takemori) on the reaction wit[h] chrome *c*, Q. H. Gibson on the re[action]

H. Beinert on the function and disposition of the copper, W. W. Wainio on some anomalous reactions of the oxidase, M. Morrison on its components and their reactions, E. C. Slater on its composition and oxidation-reduction potential, T. E. King on a cytochrome *c*–cytochrome oxidase complex, L. Smith on the reaction of the oxidase with cytochrome *c*, P. Nicholls on its mechanism and E. E. Jacobs on its reaction with high-potential electron donors. Comments from R. Lemberg and K. Okunuki, who were unable to be present, were submitted by E. C. Slater and S. Takemori. There is now general agreement that copper forms part of the enzyme, although its exact role remains to be determined. Q. H. Gibson agrees with B. F. van Gelder and E. C. Slater that equal amounts of the a and a_3 components are present in active cytochrome *c* oxidase. Gibson's discovery that cytochrome *c* oxidase preparations contain non-reducible cytochrome a_3 explains the higher ratios of $a : a_3$ reported by M. Morrison. P. Handler brought forward the coupling of sulphite oxidation with the cytochrome *c* oxidase reaction as evidence in favour of an iron–O_2^- radical as an intermediate in the enzyme reaction.

The last two sessions were devoted to oxidase systems and oxidative phosphorylation in intact mitochondria. A. W. Linnane reported on the induction by oxygen of the synthesis of mitochondria in anaerobically grown yeast cells. E. R. Redfearn discussed the interaction of electron carriers in the mitochondrial $NADH_2$ and succinate oxidase systems. Oxidative phosphorylation was dealt with in four papers. L. Ernster described a new method for investigating phosphorylation in the cytochrome *b*–*c* region, D. E. Griffiths examined possible reaction mechanisms at the pyridine nucleotide level and P. D. Boyer suggested carboxyl activation as a possible common reaction in substrate-level and oxidative phosphorylation, and in muscle contraction. Boyer stated that there is now no clear evidence for a role for phosphohistidine in oxidative phosphorylation, and that all data can be rationalized in terms of the succinyl-Co*A* synthetase being responsible for the incorporation of inorganic phosphorus-32 into mitochondrial protein-bound phosphohistidine. C. L. Wadkins reported interesting work on the oligomycin-inhibited, dinitrophenol-stimulated interaction between the ADP–ATP exchange enzyme and cytochrome *c*. B. Chance reported data on the reaction-velocity constants for electron transfer and transport reactions. He proposed that three types of reactions are volved in oxidative phosphorylation: (1) a rapid elec- transfer process, limited by the speed with which an departs from an iron atom and by the speed of its ugh the hæm-linked groups to the periphery of (2) an electron-transfer process which involves a thermal reaction in which the adjacent electron-bearing hæmatin becomes properly orientated; (3) a process involving the formation of high-energy intermediates of the cytochromes.

The last two papers dealt with the mitochondrial morphology as revealed by the electron microscope, with particular reference to the structure with projecting sub-units discovered by Fernandez-Moran. Those features of this structure which have been regarded as essential have gradually undergone a change, summarized colloquially by the sequences 'knobs', 'knobs on sticks' and 'the tripartite knobs-sticks-base plate'. There was general agreement that the morphological structure is not an artefact, but no agreement as to its physical significance. D. E. Green defended his suggestion that the structure represented the 'elementary particle' of electron transport. E. Racker, in a paper with D. F. Parsons, B. Chance and others, discussed the correlations between electron-transport activity, ATPase and the morphology of the submitochondrial particles, which led him and his colleagues to conclude that the projecting sub-units do not contribute an essential component to the electron-transport chain. A possible correlation between the sub-units and ATPase activity (coupling factor I) was suggested. Those attending the symposium were not disappointed in their expectations of a vigorous discussion, which was brought to a close by Racker's revelation that the 'knobs–sticks–base plate' structure shown by electron microscopy had been painted, in appropriate colours, by a Finnish artist in the 'thirties.

The papers presented at the symposium are to be published in due course. Since all but two of them were circulated to participants several weeks before the symposium, only 10 minutes were allowed for each presentation, hence maximum time was made available for discussion. The time-table for the symposium was planned on the hopeful assumption that the participants would have read the preprints (weighing 3·5 kg) before the meeting. Although in this respect most of the participants disappointed the organizers, the discussions were mostly lively, and there can have been few points in the field of oxidases which were left undiscussed.

If I may be permitted to record what struck me most about this symposium—and the identical thought was voiced by one of the most senior and most distinguished of the participants—it was the number, breadth and depth of the contributions made to the discussions by B. Chance, covering everything from theoretical chemistry, through physical chemistry, mechanism of enzyme action, oxidative phosphorylation to the morphology of mitochondria. It was a masterly performance, which contributed much to the high standard of the discussions. E. C. Slater

NAL AND SOCIAL FAILURE: SOME FURTHER OBSERVATIONS

By JOHN BRADLEY

School of Education, University of Leicester

ine[1] gave an account of a new which had been used to provide ent of a concept of a family ildren of school age.

ven to primary school children xes and to a group of 1,600 boys and girls of 11–15 years, t the mother is regarded as the ily in the earlier primary years y displaced by the father, the ing complete for the majority enth year.

Groups of children committed to approved schools and a group of children who had failed to make satisfactory academic and social progress in a grammar school gave a significantly different pattern of test results.

It was shown that social and educational failure, which can be defined as an obvious deviation by the child from the social and educational standards acceptable to those in whose care he finds himself outside the home, have a similar ætiology and that both can be understood only through a study of the family authority relationships and a consideration of the child's response to these relationships. It was further shown that these relationships

are as relevant to the failure of girls as to that of boys; no significant sex differences in the responses to the projection test appeared either at the primary or secondary school level, while for the approved-school girls absence of the father or his serious defection was reported in a high proportion of cases and appeared to be reflected in the test results.

The emergence of the father as first in the family hierarchy during the years 7–11+ seems to be related to the development of a conforming, socially acceptable attitude of the child. It is interesting to note that in the groups of delinquent boys the mean age of the first recorded offence was 10·2 years.

The original primary school sample was small, and the test has now been repeated in three mixed primary schools with results which are consistent with the earlier findings.

Table 1

	F.	M.	Self	Other	
Year I	24	68	12	15	119
Year II	38	57	13	12	120
Year III	38	51	30	20	139
Year IV	80	41	12	18	151
				Total	529

It was argued in the earlier report that social deviations, of which frank delinquency is only one arbitrary category, stem from relationships within the nuclear family. If this argument is valid, it seemed likely that test results of children who showed deviations from 'normal' behaviour in the secondary modern school group would show significant variations from the 'normal' family patterns in the test.

The headmaster of the secondary modern boys' school was therefore asked to give details of all children in the school who were regarded as unsatisfactory in terms of academic effort or out of the ordinary in behaviour or attitude. This deviant group included those known as petty pilferers, repeated breakers of school rules, the extremely nervous and diffident, and boys who were irresponsible and impulsive. Those whose behaviour could reasonably be attributed to organic or functional abnormalities, for example, asthmatics and cases of epilepsy and head injury, were excluded.

Full longitudinal records were available for 659 boys, and Table 2 shows the relationship which was found for this group between deviant behaviour and the member of the family placed at the top of the circle.

Table 2

	F.	M.	Br.	Sis.	Self/other	
'Normal'	350	103	22	13	22	510
Deviant	43	67	21	10	8	149
						659

The relationship is significant.

The school serves a large housing estate and a town centre area, and the large number of cases of deviant behaviour indicated in the Table is likely to be a reliable estimate, particularly as the schools keep very detailed records for each pupil.

The patterns of family dominance hierarchy for deviants in this secondary modern school are similar to those obtained from a group of 317 delinquents made up of 268 boys in approved schools and 49 boys remanded for clinical reports by the courts.

Table 3

F.	M.	Br.	Sis.	Self/other
78	129	61	30	19

The same tendency for the mother to retain the salient position in the hierarchy is apparent and resembles the patterns obtained from the first-year primary school group.

It is evident that the non-deviant and deviant groups respond differently to the projection test. If the reasons for these differences of response are to be explored it seems necessary to arrive at an objective assessment, in so far as objectivity is possible, of the relationships between parents and child and of the parts played by both parents in the family group.

Information concerning the family relationships of non-deviant children is scanty and anecdotal as families, generally, are inaccessible to systematic observation and assessment. There are no norms for attitudes in the family and no means of assessing objectively the quality of the relationships between the members of the family group. The families of delinquent children, however, come under the scrutiny of children's officers and probation officers, and if the child is committed to an approved school all available reports are brought together by the classifying school and passed on to the approved school to which the child is allocated, with any additional information gathered during the classifying period.

It is clear that the norms of family life adopted by the social workers successively involved with the child's problem will be in no way standardized. Each worker will bring to the investigation his own experience of family life, his own response to training and his own private view of all that he feels family life should entail.

His contacts with the family will be stylized and formal and, however close his relationship to the family may appear to him to be, he remains an official; consequently no more than part of the truth can be recorded since only part of the truth is ever revealed.

Furthermore, the reports of the first social worker to be involved with a family may influence significantly the reports of subsequent workers. The 'good' family tends to remain 'good' throughout the records, while the 'bad' family tends to exhibit a stubborn resistance to the social workers' efforts to modify its attitudes.

Nevertheless, since for the delinquent group the bulk of information is to be found only in such reports, it is on this information, with the reservations mentioned above, that the next part of the investigation is based.

The records of a group of 173 boys, of 11–15 years, committed to approved schools, were examined and the reported parental attitudes were recorded separately for both parents on five-point scales.

The scale for fathers was:

Table 4

1	2	3	4	5
Overstrict Rigid Harsh Domineering	Inconsistently strict	Consistently reasonable but firm: interested in child	Plays little part in controlling but sometimes weakly involved	Disinterested: abdicating: leaves all control to mother or others

The scale for mothers was:

Table 5

1	2	3	4	5
Overprotecting against blame and correction: resists father's intervention: overindulgent	Inconsistent: tends towards overprotecting: overindulgent attitude	Consistent: reasonable and participates warmly	Inconsistent: at times sentimentally overindulgent but tends to reject	Disinterested: has little or no affection: rejecting

The following results were obtained:

Fathers' reported attitude to the family:

Table 6. HARSH—RIGID←→DISINTERESTED—ABDICATING

1	2	3	4	5	
13	18	7	47	88	Total 173

Mothers' reported attitude to the family:

Table 7. OVERPROTECTING←→REJECTING

1	2	3	4	5	Insufficient information 5
31	21	21	42	53	Total 168

Of the fathers 7 (4 per cent) were, from the reports, normal in their attitudes; of the mothers 21 (12·5 per cent) were regarded as normal. No control or training was given by either parent in 67 cases (38·7 per cent). Where the mother was reported to be 'normal', the attitudes of the fathers were distributed as follows:

Table 8. Harsh—Rigid←→Disinterested—Abdicating

1	2	3	4	5	
1	–	3	2	15	Total 21

Of the three families with both parents described as 'normal', that is, falling into category 3, the parents of one family were preoccupied for the first 9 years of the subject's life with an idiot spastic sibling; and one mother was described by the classifying school as having given no moral training. The third mother suffers from psychotic episodes. One father is psychotic.

Of the fathers 36 (20·8 per cent) were unemployed; 45 (26·0 per cent) were delinquent (convicted); 9 (5·0 per cent) were delinquent and unemployed. Of the 168 mothers for whom full information was available 9 (5·3 per cent) were delinquent. Of the 173 families 74 (42 per cent) had more than one delinquent child. For this group of 173 boys the protection test gave the following family dominance pattern:

At the top of the circle:

Table 9

F.	M.	Br.	Sis.	Self/other	
42	72	39	13	7	173

The pattern in cases with fathers delinquent was:

Table 10

F.	M.	Br.	Sis.	Self/other	
12	22	6	4	1	45

and the pattern where siblings were also delinquent but father non-delinquent:

Table 11

F.	M.	Br.	Sis.	Self/other	
17	29	23	4	1	74

The records of 53 girls of 11–15 years committed to approved schools, while far less detailed and comprehensive than those for the boys, were examined in the same manner.

Of this group 25 came from broken or incomplete families, fathers being absent in 15 cases, mothers in 5 cases; the information available was inadequate in 5 cases.

Of the 28 girls from intact families who were studied, reports on parental attitudes yielded the following information:

Table 12. Fathers' Reported Attitude to the Family

1	2	3	4	5
5	7	–	3	13

Table 13. Mothers' Reported Attitude to the Family

1	2	3	4	5	Insufficient information 5
1	3	1	8	10	Total 28

Of the fathers, 5 were unemployed; 5 were delinquent; 1 was delinquent and unemployed. Of the mothers, 5 were delinquent.

The attitudes adopted by parents of delinquents of both sexes seem from this small sample of girls to be very similar. However, mothers rarely exhibit to their daughters the overprotective attitude they often show towards their sons.

No evidence was forthcoming to suggest that early separation from the mother was a significant factor in the delinquency of either sex or that the quality of the discipline and control of the mother alone as suggested by Glueck[2] was of first importance.

Mead[3], as long ago as 1950, affirmed that the cohesion of society depends on the learned nurturing behaviour of the human male. It seems clear from this present research that both parents are important in the socialization of the child but that the role of the father is more vital than has hitherto been admitted. The father who chooses to abdicate or to dominate rather than to nurture or who, because of the defects in his own rearing, is incapable of learning to nurture adds to the difficulties of his children's socialization and appears from the investigation so far carried out to be responsible in a large measure for his children's social deviation.

THE TROPICAL PRODUCTS INSTITUTE

In his report for 1963*, the director of the Tropical Products Institute, Mr. E. S. Hiscocks, states that investigations of aflatoxin and its presence in groundnuts and other materials remained the major project throughout the year, although by the end of the year the results of this work allowed all but a small nucleus of staff to return to other duties. The Institute is, however, still providing advice to most parts of the world on the problem and is maintaining close contact with other laboratories working in this field. In September, a member of the staff was seconded to Nigeria for six months to assist with work on testing samples for aflatoxin and to train local staff in this technique. In October, the Institute acted as host to an international meeting organized by the United Nations International Children's Emergency Fund on the subject of aflatoxin.

Two new projects were started during the year. The first, which arose from a growing concern about the widespread use of toxic insecticides and the concomitant problems of insect resistance and toxic residues, deals with a search for insect attractants. It is hoped that the use of such attractants, which may operate through sexual, food or ovipositional stimuli, may provide alternative methods of controlling certain tropical insects and may also overcome the problem of insect resistance to insecticides.

* Department of Scientific and Industrial Research. Report of the Tropical Products Institute 1963: The Report of the Tropical Products Institute Committee with the Report of the Director of the Tropical Products Institute. Pp. vi+33. (London: H.M.S.O., 1964.) 3s. net.

The second is an investigation of methods for local processing of tropical products with the view of improving the equipment or method, or of designing machinery where this does not exist. The first investigation, which was recently started, is concerned with the difficult problem of cashew nut decortication.

During the year, 838 enquiries were received from 78 countries and international bodies. This represents a slight decrease on the previous year which can probably be explained by the setting up of similar laboratories in various developing countries. Although such laboratories will eventually be able to take over much of the work that the Institute has carried out in the past, it means that the enquiries now received tend to come from such laboratories and concern aspects of work for which they do not have facilities. Thus, the enquiries received, although diminishing somewhat in number, tend to increase in complexity.

Among the many important investigations referred to in the report is one concerned with dried fish. The methods of drying used in the tropics are usually very primitive: the fish is laid out in the sun or placed over an open fire, and it is probable that these methods not only impair the quality of the fish but also reduce the biological value of the protein. A detailed investigation of dried fish from tropical countries has been carried out and a series of experiments was aimed at investigating the drying of fish under conditions approximating those which prevail in

both dry and humid tropical climates. The experiments were undertaken in a small Torry kiln in which tropical conditions were simulated.

Even in dry tropical climates, fish drying can normally be carried out for only 8 h a day because at sundown the temperature falls and the humidity increases. An attempt was made to determine whether hanging, stacking or pressing fish overnight gave the shortest drying time. The results of these experiments indicated that there might be some advantage in pressing during the later stages of drying, thus enabling the moisture to equilibrate. Further work with more refined apparatus will be required before definite conclusions can be drawn.

The 'available lysine' contents of three specimens of *Tilapia nilotica* from Uganda were determined by Carpenter's method in order to ascertain if any damage had been caused by the different methods of drying. The three specimens had been either fresh-frozen, or sun-dried, or fresh-frozen and later dried in a Torry kiln. It was found that the fresh-frozen fish contained most available lysine (10·7 g/16 g nitrogen) as would be expected, the sun-dried fish contained least (6·1 g/16 g nitrogen) and the kiln-dried fish gave an intermediate value (6·9 g/16 g nitrogen). Those concerned with this aspect of the Institute's work were surprised to find that the loss of available lysine in sun-drying was as great as that occurring in the manufacture of fish meal where much higher temperatures are used. However, as only three fish were used in the experiments the results were not, at the time of preparing the report, regarded as conclusive. They indicated, however, that further work on these lines would be worthwhile. Factors, other than protein deterioration, which are important in the nutritive value of fish, have not been examined as part of this investigation.

An officer was seconded to the Government of Aden during October 1962–March 1963 to investigate the problems involved in preparing dried fish for export. A survey of the curing methods in present-day use in Aden suggested that minor improvements in technique would enable the processors to make much better products. A series of fish-curing experiments was carried out and the crew of a Fisheries Department vessel was trained to demonstrate the methods evolved to local fishermen. These demonstrations included dry-salting in closed vessels instead of salting in open kench piles, proper washing of the fish using brine, and drying on raised racks in the shade instead of throwing the fish on the sand in the open sun. The success of these methods was illustrated by the fact that products made by the demonstrators fetched higher prices than the traditional products in local markets. Two fish-curing stations were designed for experimental use and built so that the experiments and demonstrations could be continued after the officers' departure.

The problem of insect infestation in Aden of dried fish during preparation and in storage was also examined. Early in the assignment it became obvious that this was a serious problem. A preliminary report on insect infestation was, therefore, prepared and forwarded to the Department of Technical Co-operation, since it was obvious that insect infestation should be investigated by an entomologist specializing in stored products.

The report recommends that demonstration of the improved curing methods should continue, that samples of the products made should be sent to overseas markets for evaluation and that experiments with species of fish at present under-exploited should continue. It is also recommended that the possibility should be investigated of erecting commercial fish-curing stations for communal use.

ROYAL INSTITUTE OF TECHNOLOGY, STOCKHOLM

PROF. H. ERDTMAN, of the Kungliga Tekniska Högskolan, Stockholm, has provided an interesting account of the Royal Institute of Technology, Stockholm, which was founded in 1827 as a 'humble' school of technology (*May and Baker Bulletin*, 6, No. 2; May 1964). The staff of the Institute then consisted of one director, two professors, two other teachers and eight other employees, including one steward and one porter. Instruction was in the fundamental subjects of "general natural knowledge, i.e., physics and chemistry, with particular reference to those of the general laws of Nature that find their most common applications in industry", and it was required to be "popular and practical rather than strictly scientific". In 1876 the Institute was transformed into an institute of technology, but in 1907 it still had only two professors of chemistry, one in 'technical chemistry' and one in 'general chemistry'. The present Kungliga Tekniska Högskolan, has nine departments and about eighty professors. There are about 750 other employees, of whom some 500 are teaching and research assistants, and in all about 4,000 students.

The Department of Chemistry now has twelve professors and three other senior lecturers, each in charge of his own branch of study: analytical chemistry, inorganic chemistry, organic chemistry, nuclear chemistry, physical chemistry, wood chemistry, chemical technology, polymer technology, paper technology, cellulose technology, food chemistry (biochemistry), fermentation chemistry, applied electro-chemistry and corrosion, heat technology, and chemical engineering equipment.

The degrees awarded by the Institute include *civilingenjor*, *teknologie licentiat*, and *teknologie doktor*. The time normally required for the first degree is four years, although in practice 4·5–5 years are often needed. The licentiate takes a further two or three years, and the doctorate yet another two or three or even longer. The licentiate corresponds roughly to an American, British or German Ph.D., and the doctorate approximates to a British D.Sc.

Students enter the Institute of Technology at the age of eighteen to twenty, and, owing to compulsory military service, male students are about twenty-five when they pass their *civilingenjorsexamen*. Approximately seventy freshmen are admitted annually to the Department of Chemistry, of whom about 10 per cent are women. Admission is competitive and far more students apply for admission than there are places. During the first two years, basic subjects are studied, for example, mathematics, physics, inorganic and organic chemistry, machine element design, and mechanics. The first courses in chemistry are elementary 'general courses', and all first- and second-year courses must be completed before starting the third-year course. During this and the fourth year, applied subjects are studied, and more advanced chemistry courses are available, but these are compulsory only for students who have chosen the relevant field of specialization. During the fourth year, specialization is much more intensive. Finally, for the *civilingenjorsexamen*, the student must carry out a small research project, requiring about three months work; about four months of practical experience in industry is also required.

Every student who has obtained a *civilingenjor's* degree may continue his studies for the licentiate and then go on to seek the degree of *teknologie doktor*. Foreign students who can show that they have taken a degree comparable to that of *civilingenjor* may be admitted to study for the licentiate and then for the doctor's degree by special

permission from the Governing Board of Sweden's three institutes of technology. The studies for the licentiate degree are much freer than those for that of *civilingenjor*. There are practically no lectures or any special courses, and only seminars to be attended. The main emphasis here is on scientific or technological research. For the doctor's degree a fairly long and thorough scientific training is required, and it is not uncommon for a *doktorand* (candidate for a doctorate) to have some ten to fifteen published papers.

Work for the higher degrees is generally sponsored by the research councils. As a rule, it is the professor who applies to these councils for fellowships for his students, and thus remains more or less responsible for the progress of their research work. In the applied subjects collaboration is often established with the appropriate industry. When the *doktorand* feels that he is ready for his *doktorsdisputation* he writes a review article covering his publications. This article constitutes his formal doctor's dissertation and is followed by a disputation.

THE ONTARIO RESEARCH FOUNDATION

THE annual report for 1963 of the Ontario Foundation* includes the reports of the director, the director of research and departmental directors, and a list of scientific and technical papers published during the year, as well as details of scientific and technical assistance given to outside organizations. Reference is made to the increasing number of requests received for the development of new instrumentation and measurement techniques for application in industry, and also to the growing acceptance of the Institute's project type of contract research. An intensive investigation of the chemistry of sporulation has been undertaken and an improved method of ballistically disintegrating spores has shown that the release of protein and dipicolinic acid by ruptured spores is followed by the release of an esterase.

Research was continued on high-purity iron and low alloy steel to determine the fundamental causes of fatigue by means of ultrasonic wave attenuation. In biochemistry much information was obtained regarding the part played by enzymes in the glucose metabolism of yeast. Further work was continued on the processing of fats and oils, emphasis being placed on the hydrogenation of fish oils and on the selectivity of hydrogenation of fats and oils in relation to operating variables. Fundamental information on the properties of chrysotile was accumulated with particular interest in the longer grades of fibres. In the Division of Organic Chemistry work continued to be concentrated on wood chemistry, including the utilization of wood, pulping, paper-making and paper additives. However, factors in the mechanism of absorption of wet-strength resins on paper were also investigated, and an investigation of the 4-methoxy*cyclo*hexene oxides and their ring opening reactions with nucleophilic reagents was completed. A detailed examination of many black spruce trees gave new information on the complex of interactions involving the character of the foliage, rate of growth and morphology of the wood.

In parasitology it was discovered that a lung worm of deer was responsible for paralytic disease in moose, and evidence was also gained that the same worm may cause paralytic disease in sheep. An intensive survey of small mammals was initiated to assess their role as intermediate hosts for the lung worms of carnivorous animals. Work on the attraction of different flies to different birds indicated the importance of smell, sight and touch stimuli. In physical chemistry, as part of a programme to develop non-nuclear uses of uranium, the possible application of uranium compounds as catalysts was investigated, for example, in the dehydrogenation of 1-butene to 1 : 3-butadiene. A process was developed for producing a flexible sheet for foamed-in-place shelters under field conditions, which can be operated down to −40° C, and the use of the sheet in shelter construction was demonstrated.

The work of the Physics Department was concerned chiefly with measurements on materials and development of instruments using new principles. The Department of Physiography completed a map of the surface features and glacial deposits for the area between the Kawartha Lakes and Algonquin Park, while a survey of 2,500 acres of the Humberstone peat bog was made to determine the amount of fibrous *Sphagnum* peat remaining.

TIDAL COMPONENTS IN HURRICANE DEVELOPMENT

By DONALD A. BRADLEY

Research Division, College of Engineering, New York University

A TOTAL of 269 individual hurricanes evolved out of North Atlantic tropical depressions during the 60 years 1899–1958, as catalogued in a standard data source[1]. The criterion for ranking a tropical storm as a hurricane is its attainment of sustained winds of force 12 on the Beaufort scale, at which intensity stage the pressure drops rapidly and distinct organization of the system into inward-spiralling bands takes place. The dates of transition from tropical storm to hurricane status of the 269 historical cyclones in question have been investigated as frequency distributions within frames of reference defined by lunar cycles.

The convention among investigators of lunar relationships to weather[2–4] is to express the Moon's position in any cycle as hundredths of the cycle elapsed, measuring from the fiducial of the cycle. Each hundredth part thereby denotes a class-interval 3° 36′ in width. Table 1 presents the four lunar variables of key concern in this enquiry.

The lower limit of the first interval (decimal 0·00), it should be clarified, lies 1° 48′ in advance of the given fiducial point so that the interval straddles the fiducial

Table 1. Decimal Reckoning of Lunar Positions

Lunar cycle	Mean length (d)	Fiducial	Mean daily increment (r)	Moving total time equivalents 10-unit (d)	13-unit (d)
Synodic	29·5306	New Moon	0·03386	2·953	3·839
Tropical	27·3216	Vernal point	0·03660	2·732	3·552
Nodical	27·2122	Ascending node	0·03675	2·721	3·538
Anomalistic	27·5546	Mean perigee	0·03629	2·755	3·582

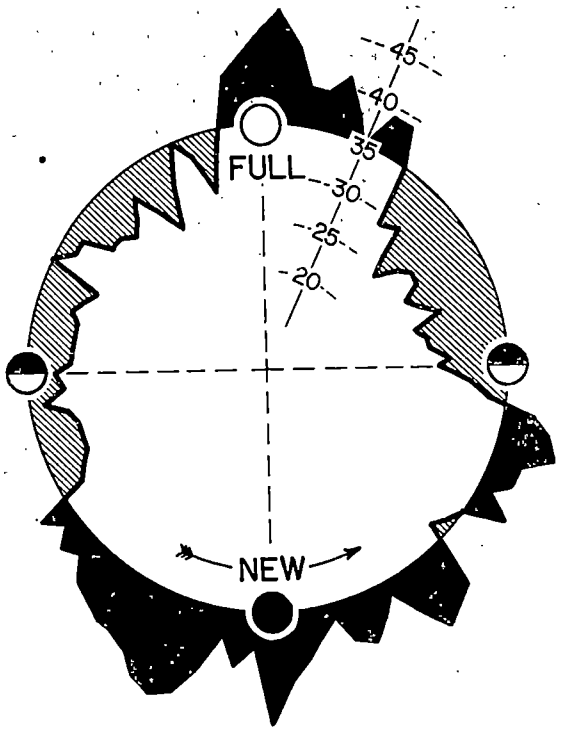

Fig. 1. Distribution along a luni-solar time-scale, shown in polar projection, of the 269 dates during 1899–1958 when North Atlantic tropical storms attained hurricane intensity. Thirteen-unit running sums of frequencies tabulated in hundredths of the 29·53-day synodic month, lunar positions taken as of 1200 G.C.T. on recorded maturation date

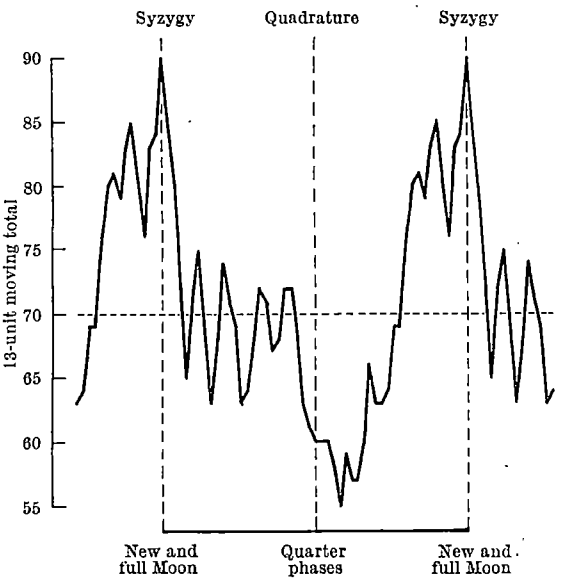

Fig. 2. The same distribution shown in Fig. 1 treated in terms of a 14·765-day cycle by superposing complementary halves of the 29·53-day synodic cycle divided at the axis of luni-solar quadrature

itself rather than commences at it. In the work recorded here, instead of using mean values, the true apparent positions of the Moon are used in two-place decimal form. As Table 1 shows, a 13-unit centred moving total, which was adopted for the distribution in synodic decimals to be discussed, roughly equates to a 3·8-day moving total, each figure thus signifying the occurrence within a segment of the cycle 46° 48′ wide. Therefore, the indicated frequency applies to activity within a range of ± 23° 24′ of an ordinate point.

Where necessary, as with handling of the lunar-distance frequencies, the curves are appropriately adjusted for differing probabilities arising from ellipticity and periodic oscillations of the Moon's orbit. For all practical purposes, it may be noted, synodic-cycle distributions of events spanning more than half a century need not be corrected for small inequalities since the divergence from linearity becomes progressively more negligible with the passage of time.

Drawing on the simplest precepts of tidal theory, if lunisolar gravitational forces impinge in any significant way on hurricane development, a statistical bias, symmetrically diphasic within the lunar month, can reasonably be expected. The two crests of such a model need not dovetail with any preconceived axis of alignment because of unknown or uncertain developmental time-lags which may be involved in generation of a hurricane. The anticipatory model requires only some statistically discernible reflexion of luni-solar variation in time and intensity.

When the 269 dates of hurricane maturation are plotted as singular events along the time-scale of the 29·53-day synodic month, a preference for near-syzygy segments of the Moon-phase cycle becomes evident. As can be seen in Fig. 1, the sunward half of the luni-solar circuit had above-average representation, the point of greatest departure from mean expectancy coinciding exactly with the event of Sun–Moon conjunction. The excess frequencies sprawl along a considerable span of the entire cycle, from shortly after last quarter phase to shortly before first quarter.

By contrast, during the other half of the cycle, excess incidence occurred only near the date of full Moon itself. The highest frequency in this hemisphere was reached within one-third of a day of the event of Sun–Moon opposition. Evaluated by several significance criteria, the distribution as a whole, with its rough symmetry around the axis of syzygy, is statistically aberrant. The primary requirement of the empirical model is therefore met.

Superposing the halves of the synodic cycle, which in effect is to treat the data in terms of the tidally fundamental 14·765-day period, yields the frequency curve shown in Fig. 2. The complete history of North Atlantic hurricane phenomena during 1899–1958 reveals that 90 of the 269 cyclones matured while the Moon was within

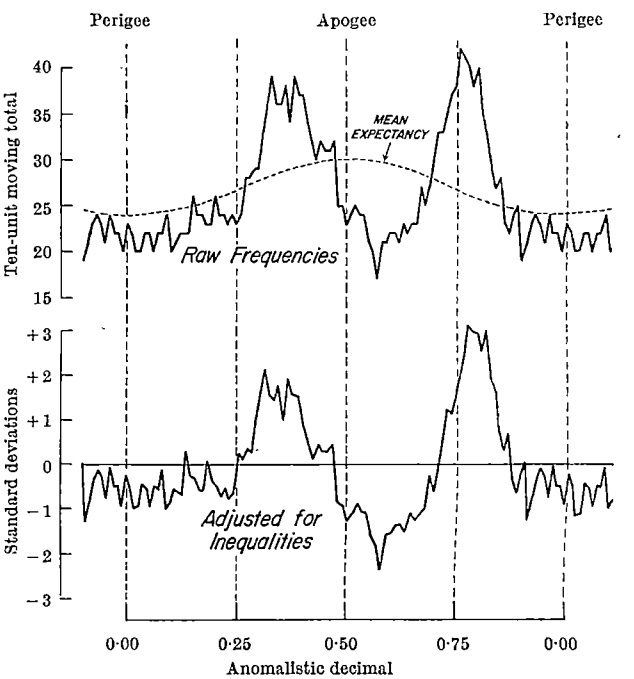

Fig. 3. Distribution of the 269 dates in terms of the Moon's longitude minus the longitude of mean perigee (top curve) and corrected for varying probabilities and orbital inequalities (bottom)

Table 2. Lunar North–South Frequencies

Group	Classification	Declination (equator)	Latitude (ecliptic)
I	Extreme north	55	56
II	Middling north	54	58
III	Near plane	57	47
IV	Middling south	48	56
V	Extreme south	55	52
	χ^2	0·870	1·428
	$n=4$	$P>0·90$	$P>0·80$

23° 24′ of the alignments known as astronomical new Moon and full Moon. In terms of mean lunar motion with respect to the Sun, this represents extreme limits of ±46 h, less than 2 days, from the hour of geocentric syzygy. The departure from mean expectancy amounts to $+2·79\sigma$ ($P < 0·01$), and, in view of its geometric agreement with expectations from accepted tidal theory, clearly argues in favour of the hypothesis of tidal components in hurricane formation suggested some time ago by L. Rodés[5] and more recently by C. H. Smiley[6,7].

Less gratifying from the point of view of theoretical expectations are the distributions of the 269 events in terms of angular departures of the Moon from the fundamental planes of either the equator or the ecliptic. Frequency tabulations of the Moon's positions in five groups for which probabilities of representation are equal in time show no significant departures from statistical likelihood (Table 2). On the basis of tidal theory and the showing made by the synodic-month distribution, a bundling of frequencies in lunar declination might reasonably be expected; but no such deviations are apparent in the north–south groupings as defined. Further investigation, however, in which the geographical co-ordinates of the individual storms are grouped with reference to the prevailing sub-solar and sub-lunar parallels of latitude, may produce quite different results.

Any model stemming from tidal theory must include, of course, the factor of varying lunar distance. The distribution of the 269 key dates along the time-scale of the anomalistic month, it turns out, is anomalous both statistically and theoretically. Fig. 3 shows both the observed and adjusted curves with their striking fold-over symmetry around points two days past the events of perigee and apogee. The trough shortly after apogee is no surprise in itself, this being the expected vicinity of minimal tidal force. What is surprising, however, is the absence of a complementary crest around perigee when tidal forces are maximal. Instead, the peaks of highest frequency were reached at points around 80° before and after the low point which lies at anomalistic decimal 0·57.

The near-orthogonality of this pattern suggested the experimental need for yet another adjustment which was incorporated into the bottom curve of Fig. 3. This adjustment was a taking into account of equal areas of *cis*-lunar space swept out by the orbiting Moon in equal intervals of time. When the proper displacements for ellipticity conditions were applied to the distribution, the two peaks were found to lie orthogonally with respect to the post-apogee low point. If the bottom curve in Fig. 3 were redrawn so that the fiducial lay at 1·9 days past the time of perigee, the peaks would fall rather neatly near 90° and 270° of 'anomalistic longitude', with the trough at 180°.

The situation thus reveals that hurricane maturation during the period 1899–1958 occurred most frequently on days when the rate of change in the intensity of the Moon's disturbing effect, and not the magnitude of the effect itself, was at a maximum. The sign of the rate of change does not appear to be important inasmuch as both the decelerating and accelerating quadrants appear to have been similarly represented in the observed frequencies.

These results suggest that the lack of significantly above-average counts around the time of perigee may be the chief reason why the possibility of tidal components in hurricane activity has been generally ignored until recently. Conceivably, previous investigators, who made probative spot-check counts of the incidence within, say, five days centred on perigee dates, may have prematurely concluded that tidal forces are of no great moment in hurricane production.

The history of hurricanes spawned over North Atlantic waters during the sixty years investigated reveals the existence of appreciably strong tidal components in the timing of their formation, as shown by significant anomalies of incidence within the luni-solar and lunar-distance cycles. The question of lunar factors involved in the generation and subsequent course of hurricanes is obviously of much importance in both theoretical and practical meteorology.

This research work was supported by the U.S. National Science Foundation, Atmospheric Sciences Program, grant *GP*–484.

FIBRE OPTICS SPECTROPHOTOMETER FOR *IN VIVO* OXIMETRY

By Dr. N. S. KAPANY and N. SILBERTRUST

Optics Technology, Inc., Belmont, California

REFLEXION and transmission spectrophotometry of specimens *in vitro* are well-established techniques. However, their use is difficult or impossible when the specimen is at a remote location or is in a dynamic state. For such applications, fibre optics probes in the form of flexible narrow tubes[1] or rigid hypodermic needles[2] can play an important part. Such an instrument capable of sampling remote and dynamic media consists of a probe composed of two fibre optics bundles: one to transmit light from an appropriate light source to the distal end, where it is in close proximity to the specimen, and the other to transmit the return signal from the specimen to a photodetector. An optical schematic of this instrument is shown in Fig. 1. The sensitivity and spectral response of this type of spectrophotometer would be a function of the source emission, the filter transmission (or monochromator), the fibre transmission and the photodetector response. Obviously, use can also be made of a single unaligned fibre bundle which conducts light from the source to the specimen as well as transmits the return signal to the photodetector. However, such a configuration suffers from noise because of scattering and 'cross talk' between the fibres. For this reason the use of a double-probe system, which consists of separate or intermingled fibres for the two functions, is preferred.

Various applications of such an instrument are apparent. Continuous monitoring of a liquid in process control would be possible, for example, in the chemical and food

industries. The spectral response of the system is primarily determined by the fibres, and with the availability of high-quality fibres capable of transmission in the regions from 3500 Å to 6μ and 1–10μ (ref. 3), sophisticated investigations of fluorescence and associated phenomena on remotely located specimens are possible. Furthermore, with the appropriate choice of wave-lengths, investigation can be made of dye concentration as well as flow velocities of dynamic fluid media. The application which has been of the greatest interest to us has been the use of this instrument in cardiac and vascular oximetry, which will be discussed in some detail in this article, and the role of the optical properties of blood under dynamic conditions in these measurements.

One of the principal measurements required by physicians is the oxygen saturation of the blood. A present method for this determination is to catheterize the heart by inserting a flexible hollow tube into a cardiac chamber and removing a sample of blood. The blood is chemically and physically prepared and then analysed by a Van Slyke or spectrophotometric process. This method requires a separate sample for each reading (a requirement which is medically undesirable in many clinical applications) and results in a serious time-delay before the oxygen saturation value is obtained. Since the time required to withdraw blood for an *in vitro* analysis is typically in the range of many seconds, small or rapid changes in blood conditions cannot be measured by this technique.

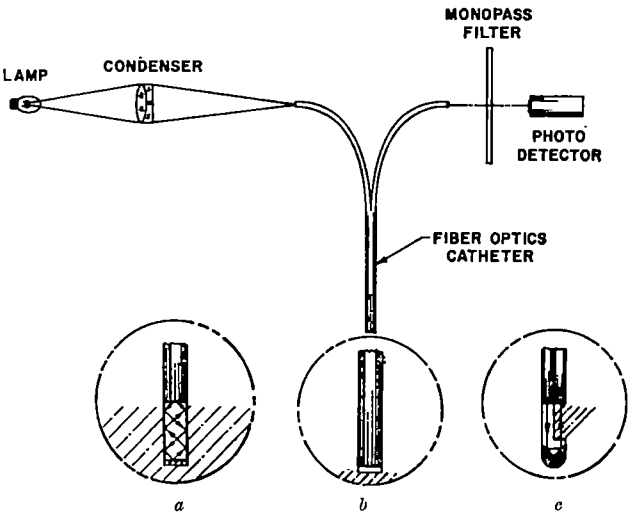

Fig. 1. Optical arrangement of *in vivo* oximeter using fibre optics, and optical designs of three different types of distal heads for: (*a*) multiple total reflexion; (*b*) reflexion; (*c*) transmission oximetry

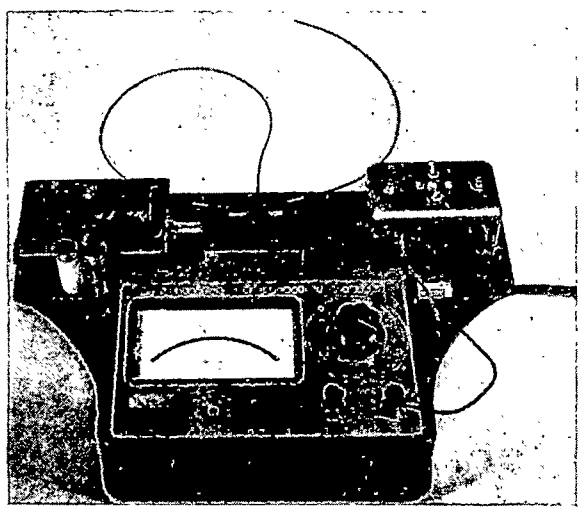

Fig. 2. Photograph of fibre optics spectrophotometer for *in vivo* oximetry. The flexible catheter consisting of fibre optics is shown at the top of the photograph

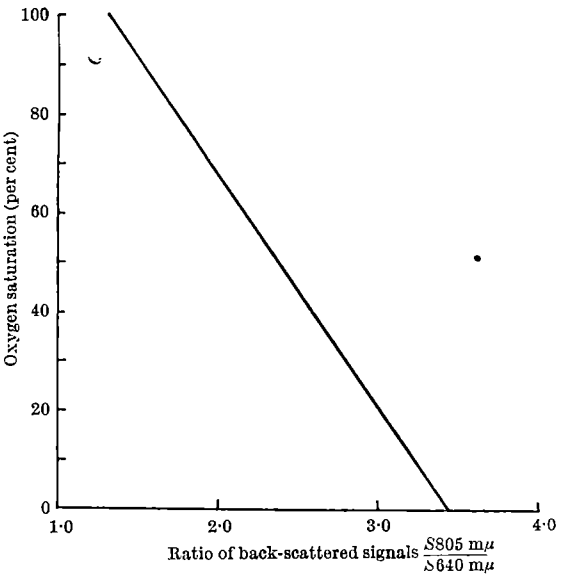

Fig. 3. Calibration of the *in vivo* fibre optics measurements against oxygen saturation determined by measurements made on conventional spectrophotometer

In vivo *oximeter*. The system illustrated diagrammatically in Fig. 1 was specifically designed to determine oxygen saturation *in vivo*. Three possible configurations of the distal head are shown. In the centre of the figure is a reflexion measuring head, which detects, at 640 mμ and 805 mμ wave-lengths, the signal generated by reflexion (back-scattering) of light from the blood cells. The head at the left is based on the multiple total internal reflexion principle similar to the photo-refractometer system[4]. The head at the right measures the signal transmitted through (or forward-scattered by) the blood within the gap. *In vivo* oximeters, of types illustrated in Fig. 1, which can be used both in 'transmission oximetry' and 'reflexion oximetry', have been constructed and tested.

Fig. 2 is a photograph of the *in vivo* oximeter. The fibre optics catheter shown at the top conducts the light from the source located on the left. A condenser lens is used to focus the light on to one of the fibre bundles and an appropriate filter (640 mμ or 805 mμ) is placed in the optical train. The return signal is transported by the fibres on to a photodetector located on the right. The signal is read out on the microammeter in the foreground, or on a strip chart recorder.

Tests of the oximeter on *in vitro* samples were satisfactory in both sensitivity and repeatability when the results were calibrated against spectrophotometric analyses of the same blood. Consequently, *in vivo* tests were initiated using live animals. The fibre optics catheter was inserted into the heart of a dog through the jugular vein. A second catheter, a standard hollow type, was passed through the femoral vein and into the same cardiac chamber. Under fluoroscopic control the two catheters were placed tip to tip. An endotracheal tube, inserted through the dog's mouth, was connected to gas cylinders of various percentages of oxygen, and in this manner the oxygen saturation of the blood was varied. The fibre optics oximeter was calibrated by matching its reading with samples that were taken simultaneously and analysed by standard laboratory techniques (Fig. 3). Similar work has been reported by Polanyi and Cournand *et al.*[5,6].

These investigations produced results so sensitive that both the respiration rate and heart beat were clearly

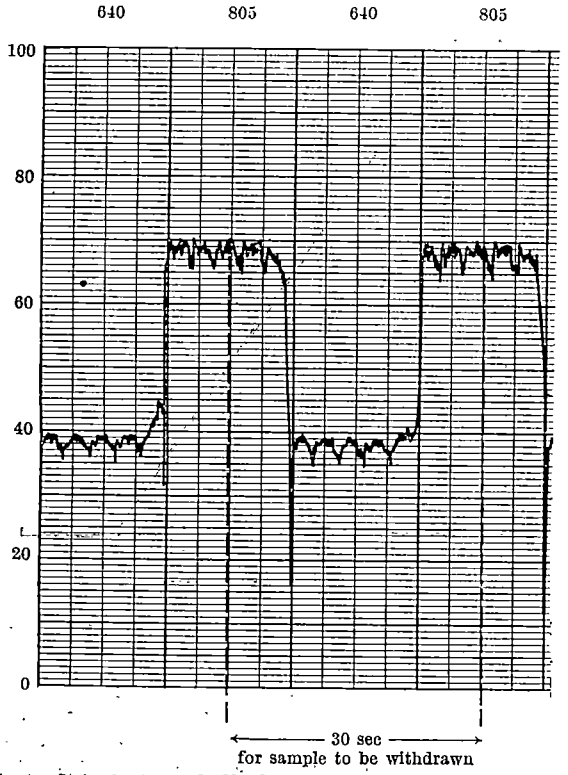

Fig. 4. Strip-chart record of back-scattering from the blood within the cardiac chambers of a dog. *In vitro* oxygen saturation, 79·4 per cent; heart rate, 186/min; respiration, 20/min

recorded on the output trace of the oximeter (Fig. 4). However, the oximeter readings versus the oxygen saturation, determined by a standard procedure, were not the same for each animal catheterization. Since the earlier *in vitro* results were satisfactory, we looked further into the optical properties of blood in a living animal to try to clarify this anomaly.

Optical properties of blood. Whole blood is a diffusing medium which does not obey Beer's Law, since the light is scattered from a random array of anisotropic non-spherical particles. Blood consists of cells and intercellular liquid, or plasma. The cells are classified as red cells, white cells and platelets. The white cells are of various sizes, but most of them in human blood are about 9μ in diameter. There are about 7,000/mm³. The platelets are short rods which are smaller than the white cells. Plasma comprises 55 per cent of the blood volume, and besides being the carrier of the cells contains many other substances, such as blood proteins, nutrients, salts and waste products. It is itself a clear, amber fluid which is 90 per cent water. The red cells, which number nearly 5 million/mm³, are disks which are 7–8μ in diameter and generally biconcave. They are a soft, flexible and elastic framework, and comprise about 44 per cent of the volume of blood. Hæmoglobin, which is deposited within the red cell, readily combines with oxygen to form an unstable compound called oxyhæmoglobin. In an oxygen-deficient environment, the oxyhæmoglobin loses its oxygen and becomes reduced hæmoglobin.

Optical oximetry is based on the colour of the blood (at 640 mμ and 805 mμ), which is dependent on the oxygen saturation. Oxygen saturation is defined as that portion of the total hæmoglobin which is oxygenated. Arterial blood, the most completely oxygenated in the body, is bright red, whereas venous blood, which has the lowest oxyhæmoglobin content, is darker. In a spectrophotometric analysis from 640 mμ to 700 mμ the largest signal difference will be indicated between oxyhæmoglobin and reduced hæmoglobin. When analysed at 805 mμ, the isobestic point, all hæmoglobin appears the same. The oxygen saturation, therefore, is proportional to the ratio of the signals received at these two wave-lengths.

In addition to oxygen saturation, many other parameters determine the optical properties of blood. These include the flow velocity, whether the flow is laminar or turbulent, the temperature, the hæmatocrit or the total number of red cells per unit volume of blood, and the concentration of any dye present. A detailed investigation into the scattering properties of blood as a function of these variables was, therefore, necessary.

For the investigation of angular scattering of blood the goniophotometer shown in Fig. 5(*a*) was designed in which an optical cell, made of two plane parallel glass plates of variable spacing, is connected to a flowing blood supply. The pump does not contact the blood itself, but partially compresses the tubing, causing pulsatile flow similar to that in a living being. The light is mechanically chopped and focused to a small spot on the cell. A photomultiplier tube, either with an *S*-20 or an *S*-1 photocathode, rotates about the centre of the cell and records the light-scattering properties of the blood as a function of angle, as various parameters of the blood are varied.

Fig. 5(*b*) is a photograph of the laboratory set-up. In the centre is the optical cell, which is connected by tubing to the blood supply in the bottle on the magnetic stirrer. The cell was carefully designed to make a smooth transition from the circular tubing to the rectangular cell so as to avoid any sharp edges that might cause turbulent flow. The pump is located at the far right. The long tube just to the right of the cell is the light source and chopper. The phototube, *x*–*y* recorder, power supplies and controls are on the left.

The equipment illustrated in Figs. 5(*a*) and (*b*) has been used for measurement of angular scattering of blood with

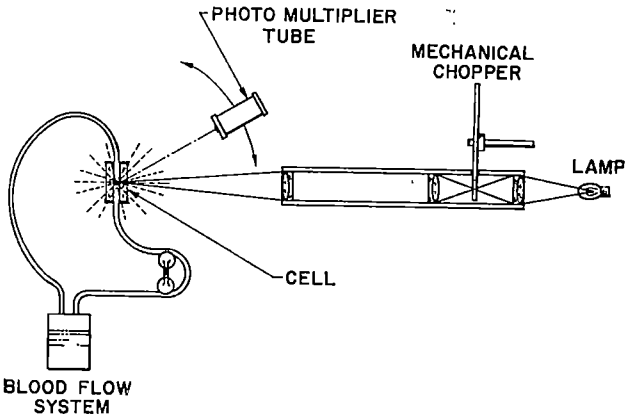

Fig. 5(*a*). Schematic diagram of the goniophotometer for measurement of forward and back-scattering of blood under static and dynamic conditions

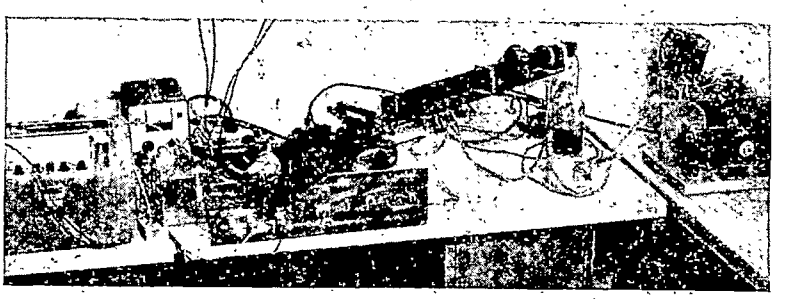

Fig. 5(*b*). Photograph of goniophotometer

different composition under static and dynamic conditions. Some representative test results obtained with the goniophotometer are shown in Figs. 6 and 7. Fig. 6(*a*) shows the scattered light-levels for 100 per cent oxygenated blood, while flowing at 0·21 l./min as a function of angle. Two wave-lengths near the region of maximum signal difference between oxyhæmoglobin and reduced hæmoglobin are shown, as are two wave-lengths near the isobestic point. It should be noted that the curves are not symmetrical. This is attributable to the asymmetrical cell orientation during laminar flow conditions. All results were collected with the photo-tube rotating in the direction of blood flow, and the highest readings are obtained in the two quadrants where the motions are in the same direction. The curves have been normalized to take account of the spectral response of the phototube and the transmission of the filters. The angular resolution of the system is approximately 1 deg. It is noted in the figure that the values fall to zero at 90 deg. This is a result of the plane parallel construction of the cell which gives rise to high internal reflexion coefficients, at the cell window, of the light scattered at highly oblique angles. For a blood thickness of 2 mm, the signal for back-scattering is almost twice as high as that for forward scattering.

Fig. 6(*b*) shows the effect of temperature on the angular scattering property of 100 per cent oxygenated blood while flowing at 0·21 l./min. This could be the result of a cellular change, since it is known that temperature variations can destroy and dissolve the red blood cells and release hæmoglobin into the plasma.

Fig. 7 indicates the effect of variation of the flow velocity on the scattering properties of blood with 100 per cent oxygen saturation. Forward scattering shows an increase in signal due to increased flow. When the flow is stopped there is a short period of decreased signal,

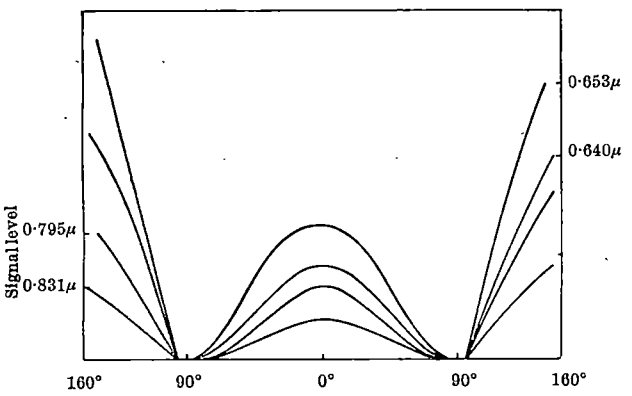

Fig. 6(*a*). Forward and back-scattering of blood with 100 per cent oxygen concentration, and flowing at 0·21/min, at 0·653, 0·640, 0·795 and 0·831μ

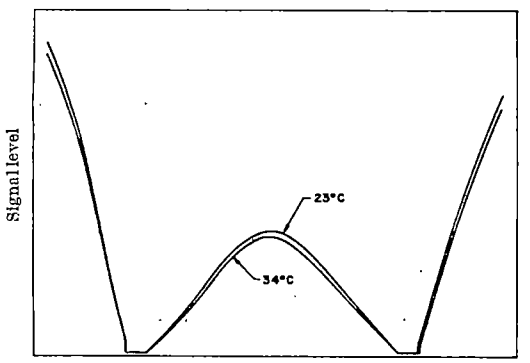

Fig. 6(*b*). Forward and back-scattering of blood at 100 per cent oxygen concentration, and flowing at 0·21 l./min, at 23° and 34° C

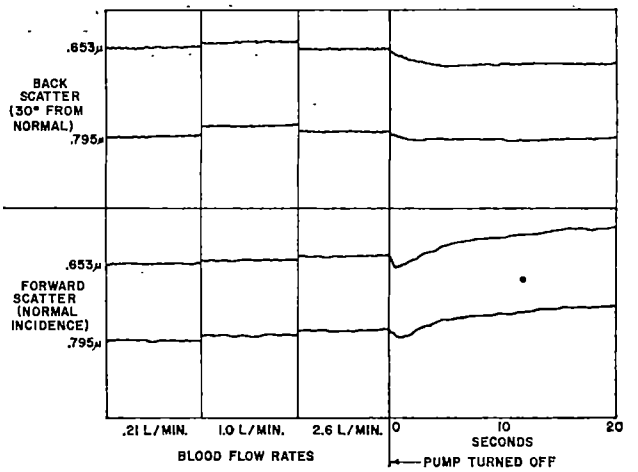

Fig. 7. Back- and forward-scattering of blood with 100 per cent oxygen concentration as a function of blood flow rate at 0·653 and 0·795μ

due to random orientation of the cells, and then there is a gradual increase in signal as the cells settle out. Back-scattering, on the other hand, shows an anomaly at the highest flow rate (well above what is normally found in the living body). It may have been that the laminar flow at the two lower flow rates changed to turbulent flow at 2·6 l./min, thereby causing a reduction in the back-scattered signal while forward scattering was increased. Additionally, there is a decrease in signal when the flow is stopped.

The results of these investigations into the optical properties of blood will be applied to the improvement of *in vivo* cardiac oximetry. They are of special significance to the photometric efficiency of the oximeter system inasmuch as the acceptance angle of the fibre optics is determined by the fibre numerical aperture. Since the ratio of the two red signals to the infra-red does not change measurably as a function of angle, the numerical aperture of the fibres does not affect the sensitivity of the *in vivo* oximeter. It is well known that fibres tend to integrate the incident light over the angle determined by their numerical aperture, and, since this does not affect the ratio of the signal at the two wave-lengths, as high a numerical aperture as possible should be used to increase the signal level.

Conclusions. *In vivo* spectrophotometry using fibre optics can be a most useful research and clinical tool in many areas of investigation, inasmuch as it permits the sampling of specimens in remote locations and in a dynamic state. The spectral properties of the specimen are immediately available, and there is no spatial or temporal integration to mask out small or rapid changes. Our experiments have shown, however, that an intensive investigation must be made when the specimen is not optically homogeneous.

It is clear that broad spectral transmission fibre optics that cover the near ultra-violet, visible and infra-red regions up to 6μ, when used with appropriate sources, filters and detectors, make possible the accurate measurement of spectral properties of remote specimens. The application of *in vivo* oximetry has been well demonstrated. An interesting example is the *in vivo* measurement of dye concentration in the heart. Furthermore, use can be made of this technique for fluorescence investigations of tissues under the skin using a fibre optics hypodermic probe.

Further detailed investigations of the angular scattering and other optical properties of the blood with different oxygen concentration, dyes and flow velocities are in progress along with investigations on the effect of laminar or turbulent flow conditions on scattering of polarized light.

We thank Dr. Herbert Hultgren and Harry Miller of the Stanford University School of Medicine and Kenneth Frame of Optics Technology, Inc., for their assistance.

FORMATION AND DECOMPOSITION OF ALKALINE 'PERNITRITE'

By Dr. HENRY M. PAPÉE and Dr. GIANNA L. PETRICONI

Centre for Aerosol Nucleation, National Research Council of Italy, Via Vettore 4 (Monte Sacro), Rome

THE reaction which leads to the formation of 'alkali–metal pernitrite' is usually carried out in the laboratory[1–3] by mixing a cold, fairly concentrated solution of alkaline nitrite with acidified hydrogen peroxide; this in turn is followed by fast alkalinization of the oxidizing mixture. The procedure, if carried out with sufficient promptness, leads to relatively fair yields and stabilization of the yellow 'pernitrite' solution, the rates of formation and decomposition of which are both strongly enhanced by the concentration of the hydrogen ion. It has so far been customary to assign the formula of H—O—O—N=O to 'pernitrous acid', although it was suggested[4] that the compound may have the structure of an acid nitrosyl-peroxide, $NO^+HO_2^-$. Neither the 'acid' nor its 'alkaline salts' have so far been isolated, and comparatively little work dealing with them has been carried out[3] despite the fact that it has been pointed out repeatedly[3,5] that solutions of the substance possess very strong oxidizing powers, in that 'pernitrite' decomposes yielding free OH radicals.

Considerable effort has recently been devoted to the examination of reactions induced in solid crystalline nitrates of alkali metals by ion bombardment[6], γ-radiation[7,8] and ultra-violet light[9], and the results obtained generally point to a decomposition of the substances examined, with ultimate formation, through free-radical steps, of nitrite ions and oxygen. At the same time recent work on both the radiolysis of alkali–metal nitrate solutions[10–12] and nitric acid[13] appears to have yielded information along a similar line, the overall reactions going through intermediate steps which may differ according to experimental conditions. It appears, therefore, quite surprising that very little work has so far been carried out on ultra-violet photolysis of nitrate solutions, although a recent contribution by Geissler[14] indicates that such alkaline solutions can be altered by ultra-violet radiation, yielding nitrites.

We feel that reaction of ultra-violet photolysis of alkali–metal nitrates may present considerable fundamental interest for a chemist, and may also offer broad interdisciplinary implications. It is in fact well known that atmospheric aerosol is largely formed of sodium chloride which, in turn, contains substantial proportions of nitrate[15–18], and that the amount of the substance in the air appears to vary with latitude[19–21]. The photolytic reaction was therefore investigated in this laboratory, and it was found that, although no apparent change in solutions of acid and neutral nitrates could offhand be obtained by ultra-violet irradiation, substantial amounts of both nitrite and 'pernitrite' appeared in concentrated alkaline solutions of sodium/potassium nitrates on irradiation, at room temperature, with the light of a wave-length shorter than 2800 Å, obtained from a high-pressure, 450-W, Hanovia mercury immersion lamp. Since it thus appears that a substance capable of slow decomposition with free OH radical yield may now be produced and temporarily 'stored' in some regions of the atmosphere during the day and according to the chemical parameters which may prevail at that time in that region, an investigation of the rates of the photolytic process has been begun in this laboratory. We shall limit ourselves here to presenting some qualitative results dealing with a few experiments on photolysis of concentrated solutions of sodium nitrate (of which terrestrial aerosol partly consists) as well as some quantitative data on the rates of decomposition of 'sodium pernitrite', under controlled conditions.

Experiments on photolysis of sodium nitrate solutions were carried out in a 5-l. 'Pyrex' flask. The flask was made to house a standard 450-W Hanovia high-pressure mercury ultra-violet lamp, which was supported in a water-cooled, quartz immersion well, built by Hanovia. The light could be filtered using filter sleeves which were inserted into the well and around the lamp. The sleeves were made of 'Vycor', 'Corex' and 'Pyrex', and therefore transparent to wave-lengths longer than 2200, 2800, 3500 Å respectively, according to specifications of the Hanovia Co. The well was immersed centrally in the solution and connected to the flask by means of a standard ground joint. The flask usually contained 3 l. of solution which could be vigorously stirred magnetically, thus enabling an intimate contact with a gas (which could be bubbled through the liquid) to be achieved during irradiation. The solution usually contained initially 500·0 $g \times l.^{-1}$ of reagent purity–sodium nitrate, and its *p*H was adjusted before each run to 12·0 with analytical reagent sodium hydroxide. A yellow coloration, due to 'pernitrite'[22], was noticed after about 1 h of irradiation with unfiltered light; the deep yellow solution was found to contain about 0·15 and 0·8 $g \times l.^{-1}$ of 'pernitrous' and nitrous acid respectively, after 24 h. The final yield appeared to be generally independent of the gas dissolved and dispersed in the liquid; the gases bubbled through the ultra-violet reactor during different tests were: nitrogen, oxygen, N_2O, all of chemical purity grade, and laboratory air. An experiment which was carried out in an evacuated flask also yielded the same result. There appeared to be no substantial changes of *p*H, as monitored by a Beckman 9600 instrument, during irradiation; no 'pernitrite' was found in solutions irradiated through 'Corex' and 'Pyrex' sleeves, after 24 h.

As observed by Gleu and Roell[1], dilute alkaline solutions of 'pernitrite' will promptly reduce permanganate to manganate only. Since it occurred to us that an estimation of 'pernitrite' by the arsenite method may yield somewhat inaccurate results[1,23], and since preliminary tests using this method led to rather scattered data, the possibility of analysing for 'pernitrite' by alkaline permanganate titration was investigated. It was found that potentiometric titration of 'pernitrite', which was prepared either by ultra-violet irradiation of nitrate solutions, or by synthesis from nitrite and hydrogen peroxide solutions, gave reproducible and satisfactory results, and all analyses were therefore carried out potentiometrically using smooth platinum versus calomel electrodes, and monitoring

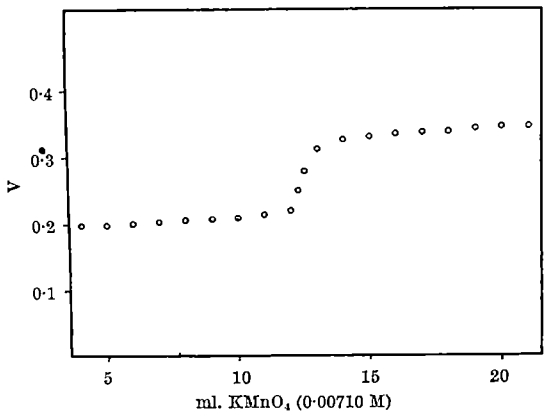

Fig. 1. Example of potentiometric titration, at room temperature, of 200 c.c. of 'pernitrite' solution prepared from $NaNO_2$ and H_2O_2, after decomposition of hydrogen peroxide by manganese dioxide

potentials by means of a Tinsley 3184-*D* instrument. It was assumed that 1 g-formula weight of 'pernitrite' corresponds, in the circumstances quoted, to 2-g-formula weights of permanganate; this was found experimentally to give results in agreement with analytical results previously quoted[1]. Fig. 1 gives an example of a representative titration.

Nitrites, in the range of concentrations used, did not appear to interfere with the procedure, and were determined on acidified solutions by the method of Lunge, as quoted by Treadwell[24]; all other salts which were used for the preparation of solutions were of analytical reagent grade and were desiccated at 140° C for 48 h, and afterwards weighed amounts thereof were dissolved in known volumes of solution.

In general agreement with the procedure described in ref. 3, aliquots of approximately 125 c.c. of aqueous solutions containing 5·0 g of sodium nitrite of analytical reagent purity were added with approximately 125 c.c. of distilled water containing 7·5 c.c. of 35 per cent hydrogen peroxide and 2·0 c.c. of 96 per cent sulphuric acid. The resulting mixture was promptly poured into 250 c.c. of aqueous solution containing 12·5 g sodium hydroxide. In further agreement with ref. 3, it was established that a delay of a few seconds in 'quenching' the acid 'pernitrite' with alkali would have brought about the decomposition of the substance. Since earlier work[23] pointed out that the decomposition of 'pernitrite' might be enhanced by hydrogen peroxide, and because hydrogen peroxide could not be found by the titanium sulphate test in the photolysed solutions, and since, probably, this peroxide is not contained in appreciable amounts in atmospheric aerosols, the excess of hydrogen peroxide was later destroyed by repulping for 5 min with about 2 g of finely subdivided manganese dioxide. This was followed by filtration through a layer of chromatography-grade silica gel, and the solution was refiltered again after standing for 2 h. The clear solutions were thereafter treated with known amounts of some of such salts as may be present in atmospheric aerosols, brought up to 1·000 litre of volume with distilled water, adjusted to *p*H 12 and left in a thermostat at 25·0° C, for periods of time ranging up to one week. Samples were taken at suitable time intervals and analysed for 'pernitrite' and nitrite by the methods outlined here.

If, in agreement with previous work[22], the process of 'pernitrite' decomposition is assumed to proceed unimolecularly, then, with other parameters constant, the following equation stands:

$$\frac{dp}{dt} = -K\,p \qquad (1)$$

Therefore:

$$\log_e p = -Kt + \log_e p_0 \qquad (2)$$

where p and p_0 stand for concentrations of 'pernitrite' at time t and t_0 respectively, and K is a constant.

Since it has already been established quantitatively[3] that there is proportionality between the rates of 'pernitrite' decomposition and the hydrogen-ion concentration, and since, on the other hand, it is known[23] that this rate strongly increases with temperature, all our experiments were carried out keeping those parameters constant. Fig. 2 gives an example of rates of 'pernitrite' decomposition with time and for different concentrations of sodium nitrate in solution, while Fig. 3 shows the relationship between constant K and the nitrate content. Concentrations of nitrite were here of the order of 1·5 g × l.$^{-1}$ and did not vary appreciably during the experiments. It was found, however, that decomposition of 'pernitrite' was 'accelerated', in our experimental conditions, by nitrite; this is substantiated by Fig. 4, which gives values of K as function of nitrite in solution and at nitrate concentrations of about 3 g × l.$^{-1}$.

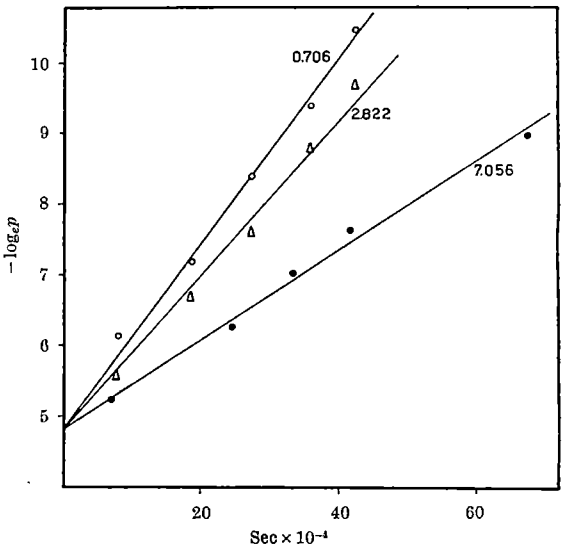

Fig. 2. Plots of natural logarithms of molar concentrations of 'pernitrite,' against time. The oxidant was prepared from nitrite and hydrogen peroxide, and the excess hydrogen peroxide decomposed by MnO_2. Molar concentrations of sodium nitrate are given near plots which were linearly regressed as a family of lines with common intercept (ref. 25)

The experiments which are illustrated in Figs. 2–4 were almost all carried out using 'pernitrite' solutions prepared from sodium nitrite and hydrogen peroxide. Preliminary results dealing with photolysed nitrate solutions gave rates of decomposition which were considerably higher than those quoted here. It was, however, noted that treatment of photolysed solutions of sodium nitrate with MnO_2, followed by filtration through silica gel, decreased the velocity of decomposition of the yellow product. The first-order rates obtained at 25° C by alkaline–permanganate potentiometry agreed very well with those obtained on peroxide-prepared 'pernitrite', as is substantiated by Fig. 3.

It can therefore be assumed that, as the photolysed solutions responded to all qualitative tests quoted in the literature in the same manner as solutions of 'pernitrite', and since they appear to decompose with identical rates at the experimental conditions described, the compound formed during ultra-violet photolysis of alkaline nitrate solutions of alkali metals effectively corresponds to the 'pernitrous' species, such as described in previous work which deals with the subject.

We have, furthermore, found that addition of chloride or sulphate ions to nitrate solutions prepared for photolysis tends to diminish the yield of 'pernitrite' formed by ultra-violet irradiation of alkaline nitrates dissolved. On the other hand, addition of small amounts of sodium chloride or sulphate to the solutions of 'perni-

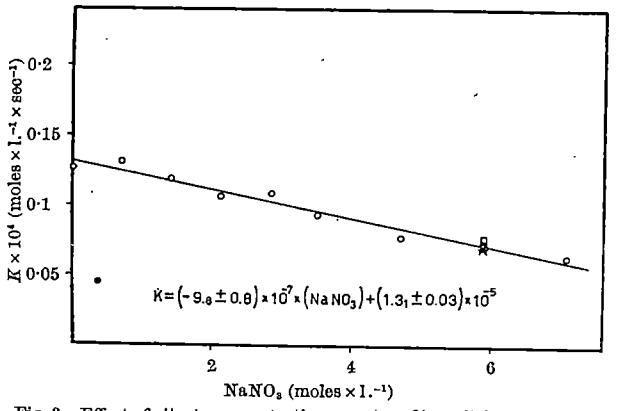

Fig. 3. Effect of nitrate concentration on rates of 'pernitrite' decomposition. All solutions were treated with MnO_2. ○, from hydrogen peroxide and sodium nitrite; □, △, ★, by photolysis of sodium nitrate with nitrogen, oxygen and air respectively

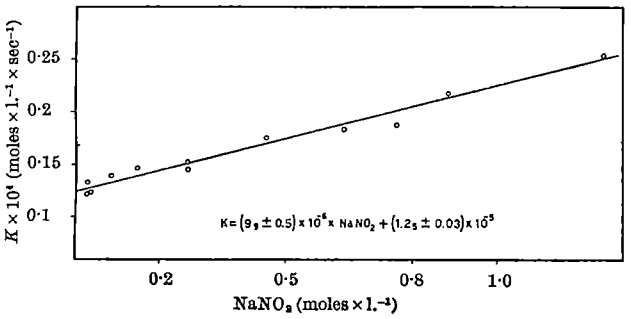

Fig. 4. Effect of nitrite concentration on rates of 'pernitrite' decomposition. All solutions were prepared from sodium nitrite and hydrogen peroxide afterwards treated with MnO_2

trite' prepared from hydrogen peroxide and sodium nitrite appears in both cases to increase slightly the rates of decomposition. Since, however, despite such additions, 'pernitrite' can still be found in the photolysed solutions of alkaline nitrate after more than 24 h of standing, it can safely be assumed that photolysed, basic, alkaline nitrate-bearing terrestrial aerosol may maintain its oxidizing activity for prolonged periods of time.

Refs. 3 and 5 strongly emphasize the role of 'pernitrite' in some organic reactions. Apart, therefore, from corrosion problems of both organic and inorganic nature, and problems which can be due to the processes of oxidation through OH-radical attack which is favoured in turn by 'pernitrite'-bearing aerosol, it is thought that the substance may have a bearing on some present-day problems, such as air-pollution and smog-formation, and that, more broadly, attention should be directed to its possible role in biology.

USE OF PROTEOLYTIC ENZYMES IN STRUCTURAL INVESTIGATIONS OF WOOL KERATIN

By B. D. GREENWOOD and Dr. P. T. SPEAKMAN

Department of Textile Industries, University of Leeds

In order to understand the structure of keratin fibres at a molecular level we are attempting to dissolve molecules or aggregates of molecules from wool keratin by mild treatments. We hope that by carefully controlled extraction it will be possible to bring the molecules or aggregates into solution in the same configuration as they possess in the original fibre. Examination of the protein in solution by biochemical and biophysical methods might then suggest how the molecules are arranged in native wool keratin.

Proteolytic enzymes have been used to investigate the structure of proteins at two levels. Each enzyme hydrolyses protein chains at certain specific amino-acid residues, but for reaction to occur the enzyme molecule requires the part of the substrate protein containing the specific amino-acid residue to be able to assume a specific configuration in the enzyme-substrate complex[1]. With substrate molecules in a random coil this can occur, but if the molecules are in a definite native configuration, peptide bonds at the specific amino-acid residues can only be attacked if they are in parts of the molecule with some freedom of movement. For example, the triple helix of tropocollagen is resistant to pepsin and chymotrypsin, but small peptide chains attached to the molecule are digested[2]. Thus proteins in a random coil in solution are hydrolysed at all the specific amino-acid residues by trypsin, and sequence studies are then possible on the small peptides which are released[3]. When proteolytic enzymes react with proteins in their native configuration fewer peptide bonds break immediately and, instead of small peptides, large fragments of the original molecule result, which are still in a definite configuration. Limited digestion of myosin by trypsin gives rise to two large fragments[4] (S = 2·5 and 5·3). The same approach has been used in structural studies of γ-globulin[5] and fibrinogen[6].

Keratin fibres are digested only slowly by proteolytic enzymes[7], and it seems likely that stability in the presence of enzymes is necessary for keratin protein to be able to resist decomposition by micro-organisms in the absence of a blood supply as a source of antibodies. However, keratinolytic enzymes have been reported from clothes moth larvæ[8], where a high pH is necessary for attack, from the bacterium *Streptomyces fradiae*[9] which can dissolve about 30 per cent of wool at pH 9, and from other micro-

organisms[10]; in this last case losses in weight were not measured.

In this article we describe experiments designed to discover the reasons for the resistance of wool keratin to digestion by the enzymes trypsin, chymotrypsin and pepsin. In another communication we shall describe how the resistance to enzyme attack may be overcome without irreversibly denaturing the wool protein, and how large protein fragments may be brought into solution.

64's New South Wales Merino wool was used throughout this work. It was purified by soxhlet extraction for 24 h in ether, rinsed twice in ethanol at room temperature, rinsed for several days in tap water and distilled water, and allowed to dry at room temperature and humidity. It was then conditioned and stored for use at 22° C and 65 per cent relative humidity. During each run two accurately weighed samples were dried over phosphorus pentoxide *in vacuo* to determine the moisture content of the conditioned wool.

Approximately 50-mg samples of conditioned wool were accurately weighed and treated with 10 ml. of a 0·05 per cent trypsin solution in 0·1 M phosphate buffer adjusted to *p*H 7·8. The tubes containing the wool and trypsin solution were immersed in a thermostat at 35° C. Every 24 h the supernatant was poured off and a fresh aliquot of enzyme solution in buffer added. The enzyme solution was stored at 4° C. At intervals the contents of a tube were rinsed several times in distilled water, dried over phosphorus pentoxide *in vacuo* and weighed. Curve I of Fig. 1 shows the loss in weight of the wool in this treatment. In this run cortical and cuticle cells released from the fibres were lost while renewing the enzyme solution every day, and during the final rinsing. To discover whether the weight loss was due to protein dissolved from the fibre or to the loss of intact cells by the fibre, an identical experiment was carried out, except that in this run loss of cells was prevented by centrifuging the wool and enzyme solutions at 1,250*g* for 5 min before pouring off the solution and adding another aliquot, and between the final rinses. The results are shown in curve II. Comparison of curves I and II shows that the main weight loss in trypsin is due to freeing of cells from the fibres, not to protein dissolving. In all the following experiments, centrifugation was used to prevent loss of cells during and after the enzyme treatments.

During 19 days only small amounts of protein were released from wool by trypsin treatment under optimum conditions. Two explanations of this result are possible: Either peptide bonds in wool keratin cannot be hydrolysed by trypsin or, alternatively, certain bonds may be hydrolysed, but hydrogen bonds or disulphide bonds prevent release of any protein into solution.

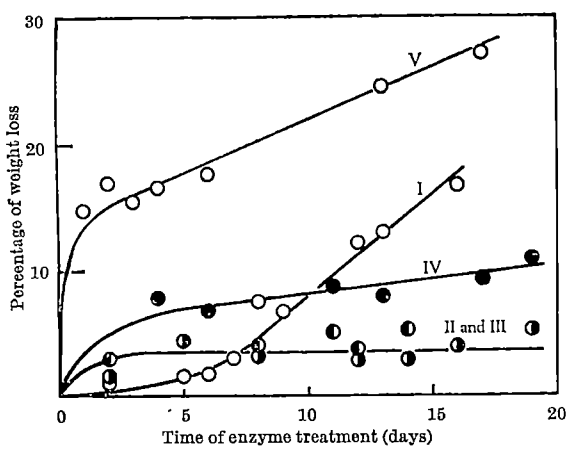

Fig. 1. Curve I: loss in weight of Merino wool treated with daily aliquots of trypsin at *p*H 7·8 and 35° C: this includes loss of cells detached by the enzyme from the fibres; curve II (◑), wool treated with trypsin as before. In this and the following runs the cells released in the treatments were collected by centrifugation and included in the final weighings; Curve III (◐), wool treated with chymotrypsin at *p*H 7·8 and 35° C followed by 8 M urea at 35° C for 12 h; curve IV, wool treated with trypsin at *p*H 7·8 and 35° C followed by 0·1 M thioglycollic acid buffered at *p*H 8·0 for 24 h at 22° C; curve V, powdered wool (see text) treated with trypsin at *p*H 8 and 35° C

Therefore, similarly weighed wool samples were treated in centrifuge tubes with chymotrypsin (wool–enzyme ratio 10 : 1) in 0·1 M phosphate buffer at *p*H 7·8 and 35° C, changing the enzyme solution daily, as before. Samples were treated for different times and then rinsed in distilled water and transferred to 8-M urea solution at 35° C for 12 h. After rinsing they were dried and weighed. Again, the weight loss in these experiments was small (curve III). Similar experiments with trypsin and pepsin at their optimum *p*H's also showed only small weight losses.

Thus a hydrogen-bond-breaking reagent did not release any protein from enzyme-treated wool. It was still possible that the enzyme might bring about some hydrolysis of peptide bonds but that protein fragments might be prevented from dissolving by disulphide cross links. Weighed wool samples were treated with daily aliquots of trypsin (wool–enzyme ratio 25 : 1) in *p*H 7·8 buffer at 35° C for up to 19 days, rinsed several times in distilled water, and then transferred to a reducing solution, 0·1 M thioglycollic acid, 0·1 M disodium hydrogen phosphate, adjusted to *p*H 8·0, for 24 h at 22° C. The enzyme treatment did not increase the amount of wool soluble in the reducing solution under these conditions (curve IV). Treatment with chymotrypsin before reduction at *p*H 8, and trypsin treatment followed by reduction at *p*H 10, gave similar results.

It appeared, therefore, that none of the wool protein was susceptible to attack by digestive tract enzymes. The small weight losses are indeed a measure of the small extent of enzyme reaction with keratin proteins. As a final check, base uptake to maintain the *p*H at 8·0 during 10 h reaction of wool with trypsin (50 : 1) at 20° C under carbon dioxide-free nitrogen in carbon dioxide-free 0·1 N sodium chloride, was compared with base uptake in a control experiment under identical conditions with no wool present. The curves are identical, showing that the only reaction which takes place is the autodigestion of trypsin.

What, then, is the cause of the resistance of the proteins of wool to attack by proteolytic enzymes? Perhaps one function of the fibre epicuticle and cell membranes[11] in Nature is to prevent enzymes from micro-organisms entering the fibre. Rather than use non-specific chemical methods to break the fibre and cell membranes, we have used mechanical methods. The same purified Merino wool was first ground under liquid nitrogen, and the light microscope shows that this produces very short lengths of fibre. After this treatment the ground wool was dried and then ball-milled in a 250-ml. glass jar five-eighths full of $\frac{3}{16}$-in. glass beads in the presence of benzene which had been distilled from sodium metal. After powdering in this way for one week at room temperature, the microscope showed pieces of fibre which were smaller than cortical cell dimensions, and, therefore, both fibre and cell membranes must have been broken. Dry 50-mg samples of the powdered wool were weighed into centrifuge tubes and allowed to react for times up to 17 days with daily aliquots of trypsin (powder–enzyme, 50 : 1) in *p*H 8 buffer at 35° C. There is an increase in the amount dissolved compared with intact wool (curve V), part of which may be due to some denaturation of the wool protein in the mechanical treatment. But the experiment shows that breaking cell and fibre membranes does not allow extensive enzyme attack. The membranes may contribute to the stability of wool keratin in solutions of proteolytic enzymes, but they are not the only cause.

Enzymes can hydrolyse peptide bonds in native proteins if part of the native structure has certain freedom of movement. Perhaps the extensive disulphide cross-linking and hydrogen bonding do not allow any part of the keratin protein molecules to come into the configuration the proteolytic enzyme requires to cause hydrolysis. Our final experiment was to extend, by 40 per cent, weighed 0·1 to

0·2-g bundles of Wensleydale fibres (purified as the Merino wool) mounted in metal frames. The extended fibres were treated with chymotrypsin (wool–enzyme ratio 20 : 1) in phosphate buffer *p*H 7·7 at 35° C for 2 days. The fibres were removed from the frame, rinsed in distilled water, dried and weighed, and the weight loss was less than 4 per cent. Altering the molecular structure of the fibres by stretching had not increased the rate of hydrolysis by chymotrypsin. Thus the configuration of the molecules in the native fibre is not the only source of enzyme resistance.

The molecules of wool keratin are, therefore, shown to be proteins which are almost completely resistant to hydrolysis catalysed by proteolytic enzymes. Deuterium exchange by native wool shows that about 25 per cent of the protein is in the α-helix structure[12], and this fraction would be expected to be resistant to enzymatic hydrolysis. Part of the remaining protein may be in a definite, repeating structure which for various reasons does not give rise to a wide-angle X-ray diffraction pattern, and again the definite structure would prevent hydrolysis. Some of the protein may also be in a random structure but so firmly held by disulphide cross-links that the molecules do not have enough freedom of movement to allow enzyme catalysed hydrolysis. Wool keratin is not highly swollen in water because of the cross-linked structure, so that enzyme penetration of the fibre may be slow.

We are at present examining chemical treatments which allow increased swelling in the fibre but do not irreversibly destroy the α-helix structure. From these swollen fibres we have evidence that large protein fragments are released by enzyme attack.

A PROCEDURE FOR THE STANDARDIZATION OF TISSUE CULTURE MEDIA

By Dr. LEONARD HAYFLICK

Wistar Institute of Anatomy and Biology, Philadelphia

AND

PAT JACOBS and FRANK PERKINS

Division of Immunological Products Control, National Institute for Medical Research, London

VARIATIONS in the purity of reagents used for Media preparations are one of the greatest sources of error encountered in the cultivation of animal cells *in vitro*. The situation is further confused by the publication of media formulæ without a precise recipe[1,2]. Both circumstances greatly influence the reproducibility of results within and between laboratories.

This problem is particularly important to those engaged in the distribution of large numbers of cell cultures having unique properties. In the course of distributing over 500 starter cultures of the human diploid cell strains *WI*-26 and *WI*-38, it soon became apparent that although the recipients used the suggested Eagle's Basal Medium[1,3] many had difficulty in propagating them. This was often traceable to variations in reagent purity and discrepancies in compounding a published formula for which no consistent recipe is available. The group of laboratories associated with the Cell Culture Collection Committee[4], which are charged with the responsibility of characterizing cultures of heteroploid cell lines distributed through the American Type Culture Collection[5], have also had similar experiences.

We have recently completed investigations with a number of widely used media formulæ which indicate that standardized media of constant composition can be prepared. The major factor contributing to its resolution was the finding by Swim and Parker[6] that, contrary to common practice, it is not necessary to dissolve, in specific groups or 'blocks', the reagents composing many media formulæ. For example, by this procedure all the amino-acids (requiring a very low *p*H), all the vitamins, and all the inorganic salts are dissolved in separate blocks. Often the constituents of each block must be added in an ordered sequence before the blocks are combined. These 'principles' of media preparation have been accepted apparently without challenge and were probably carried over to the preparation of synthetic media from the earlier and similar practices used in the compounding of balanced salt solutions. Thus, it had been tacitly assumed that the simpler procedure of pulverizing preweighed components with a pestle and mortar or ball mill and adding the mixture to water would not be successful.

The earlier report of Swim and Parker[6] indicated that although this approach was feasible under certain conditions, such compounds as L-cystine, glutamine, calcium chloride and some vitamins should be added separately. It is our purpose to report on the production of a number of the more common media by this method without any omissions and to point out the concomitant advantages.

The powdered media used in these investigations were supplied by General Biochemicals, Inc., Laboratory Park, Chagrin Falls, Ohio. Although these investigations were exhaustively performed with Eagle's Basal Medium, favourable results were obtained in our Laboratories and by others[7] with Minimal Essential Medium, Eagle[2], 199 (ref. 8) and N.C.T.C. 109 (ref. 9). The purity of the amino-acids used in these formulæ was equivalent to that recommended by the Committee on Biological Chemistry of the U.S. National Academy of Sciences[10]. The vitamins used were *United States Pharmacopoeia* grade and inorganic salts were analytical grade. Earle's, Hanks's and Gey's balanced salt solutions can also be prepared by this process. All media were prepared by combining the weighed ingredients and desiccating the aggregate over sodium hydroxide for 18 h under vacuum. The mixture was then ball-milled until a free-flowing fine powder was obtained, re-desiccated to remove moisture acquired during the milling procedure, and then packaged for use. The ball-mills are constructed of porcelain and contain 'Burundum' balls, 1·3 cm in diameter.

Eagle's Basal Medium, thus prepared, contains all the ingredients of the original formula with the one exception of sodium bicarbonate. The reason for excluding sodium

bicarbonate from the mixture was to allow wider variations in individual requirements for this substance which are dependent on: (1) the *p*H of the water used for reconstitution of the powder; (2) variations in gas-phase and liquid-phase ratios in culture vessels of differing design; (3) variations in acid-production and *p*H tolerance by different cell populations; (4) the interrelationship of these parameters with cell inoculation density. Thus the incorporation of a specific amount of sodium bicarbonate into a medium restricts its flexibility, while the absence of it permits adjustments to be made to suit individual requirements.

Powdered Eagle's Basal Medium, in aliquots sufficient to prepare 10 l., was reconstituted for use by adding 92·9 g slowly to 1 l. of de-ionized or distilled water at room temperature, agitating with a magnetic stirrer for 20 min. The resulting solution was sterilized by 'Millipore' filtration and, as a 10 *X* stock, was aseptically added to 9 l. of water sterilized in the autoclave. Alternatively, the powder can be added directly to 10 l. of water and sterilized by filtration. For cultivation of human diploid cells, the medium is supplemented with sufficient sodium bicarbonate to obtain a *p*H of 7·3, 50 μg of aureomycin per ml., and 10 per cent calf serum. The use of aureomycin instead of streptomycin and penicillin has completely prevented mycoplasma contamination in more than 5,000 tissue cultures examined during the past four years[11,12].

The assessment of efficacy of powdered Eagle's Basal Medium was made in comparison with other commercially available 10 *X* and 100 *X* liquid stock concentrates of this formula and also with liquid media prepared in our laboratories. The cell lines used in this work included HeLa, *L*, *WISH* and *H.Ep.* No. 2. The most exhaustive investigations, however, were done with the human diploid cell strains *WI*-26 and *WI*-38, which are generally considered to be more fastidious in their media requirements and also more likely to be sensitive to the presence of toxic factors. The plating efficiency, subsequent to passage for at least six generations, of *WI*-38 in powdered Eagle's Basal Medium was 18 per cent in comparison with 20 per cent obtained in control media. Cell counts made at each passage of cultures of *WI*-38 that had been growing on powdered Eagle's Basal Medium for as many as forty generations did not vary from control values. Results obtained with other diploid cell strains, primary cultures and heteroploid cell lines indicated that, of those parameters measured (for example, plating efficiency, growth rate, cell density per unit period of time, morphology, virus sensitivity, preservation and reconstitution from storage in liquid nitrogen), cell behaviour was similar in both powdered and control Eagle's Basal Medium.

The results of these experiments indicate that powdered Eagle's Basal Medium and other tissue culture media formulæ are identical in their growth-promoting properties to conventionally prepared media.

The most important of numerous advantages of dry powdered media is that large amounts can be prepared from a single source of reagents and their composition standardized. The product can then be used by large numbers of laboratories for long periods of time. So far, we have produced 100 kg of Eagle's Basal Medium for use by a number of laboratories engaged in investigations with the human diploid cell strain *WI*-38. Thus, 10,000 l. of media are available from a single standard source and the preparation of even larger quantities of powdered media is feasible. The following are also of importance:

(1) The hygroscopic powder, when kept at 5° C, dry and in the dark, has been found to be stable for at least a year. Stability investigations over longer periods are in progress.

(2) The media can be packaged to contain any volume of powder sufficient to prepare aliquots of 100 ml., 1, 5 or 10 l.

(3) Although long-term storage of the powder should be accomplished as recommended here, powdered medium is stable at room temperature for at least several weeks. Thus, it is possible to transport it in approximately 1/1,000 of the space and weight required to ship even stock liquid concentrates, thereby effecting a considerable reduction in shipping costs.

(4) Packaging of the powdered media is made in air-tight plastic bags, which all but obviates losses due to breakage or spoilage in transit.

(5) The cost of powdered Eagle's Basal Medium and other media is approximately 1/20 that of presently available commercial stock concentrates, and approximately 1/40 that of single strength commercial media.

(6) A significant cost reduction can also be realized by those laboratories which compound media from the chemical reagents themselves, not to mention the saving in time for weighing and preparation, which are liable to error.

Although not limited to Eagle's Basal Medium reconstituted from powdered media, a further refinement in the technique for sterility control of this media formulation has been attained. Contrary to the usual practice of storing prepared media at 0°–10° C, Eagle's Basal Medium is stable for at least a month at room temperature. Subsequent to reconstitution and filtration of powdered Eagle's Basal Medium, the *p*H is raised with the usual amount of sodium bicarbonate and the entire volume of media is held at room temperature for 3 4 weeks. If after this time it is found to be sterile by macroscopic observation, L-glutamine and the usual concentrations of aureomycin and serum are added before use. The question of the necessity for adding additional L-glutamine at this time is now under investigation. Media managed in this way have been found to differ not at all from Eagle's Basal Medium conventionally prepared and held at 5° C. This procedure ensures a sterility test on the entire media batch and obviates sampling errors inherent in the conventional methods.

The increasing interest in the utilization of a well-characterized human diploid cell strain for human virus vaccine production[13] results in a further practical advantage of a standardized medium available for use by numerous laboratories for long periods of time. The use of these passaged cell populations for the production of virus vaccines has resulted in the establishment of minimum criteria for vaccine production[14,15]. These criteria can now be made even more uniform by including in them the use of a standard medium.

MECHANISM OF INTESTINAL ABSORPTION: THE CONCEPT OF A SPECTRUM OF INTRACELLULAR PLASMA

By Dr. J. A. NISSIM

Department of Pharmacology, Guy's Hospital Medical School, London, S.E.1

A GREAT deal of research has been carried out in the past forty years or so on the intestinal absorption of glucose, amino-acids and short-chain fatty acids, that is, nutrient substances which are now known to be actively transported against a gradient. In particular, the absorption of glucose has been intensively examined by numerous workers, yet the exact mechanism has persistently eluded all attempts at elucidation. Of the many hypotheses advanced for the mechanism of glucose absorption, I shall mention the only two which are seriously discussed in recent reviews[1–3]. The first involves chemical alteration of the compound during transport to maintain a steep gradient for free sugar. This hypothesis was originally suggested by Höber[4], and developed into the phosphorylation theory by Wilbrandt and Laszt (1933).

According to one variant of this theory, the glucose is converted to two triose phosphates and recondensed into glucose on the serosal side. Besides many objections to this theory, it was finally discredited when it was shown that both 1-deoxyglucose and 6-deoxyglucose, neither of which could be phosphorylated, were transported uphill just like D-glucose. The second hypothesis is that of the multiple hydrogen-bond theory put forward by Rosenberg[5]. According to this, reaction with a carrier involved hydrogen-bond formation between OH groups of the sugar and suitable receptors, so that each OH group contributed to the over-all affinity, but the carrier remained unspecified. Thus, little headway has in fact been made in characterizing the carrier transport mechanism, beyond a conjecture that it was probably protein in nature[6]. Further, investigations of intestinal absorption in general have so far yielded negative results, and no positive theory has been put forward successfully. Finally, none of the theories proposed has explained the anti-leakage mechanism by which glucose is prevented from diffusing back into the intestinal lumen.

The discovery of the potent action of cetrimide on intestinal absorption has provided a powerful new tool for the investigation of the complex mechanism involved. The striking reversal of glucose flow in the rabbit, guinea pig, rat and mouse (ref. 7, and unpublished observations) demonstrated the paralysis of the anti-leakage mechanism for the first time. Taylor[8] concluded from his investigations that the action of cetrimide was not specific, but resulted probably from interference with cellular aerobic metabolism or damage to the intestinal mucosa. This cannot be a correct explanation, however, for in the rabbit the absorption of methionine and butyrate continued undiminished at concentrations of cetrimide which caused the glucose to leak back into the lumen. The effect of cetrimide was reversible both *in vivo* and *in vitro* perfusion experiments, as the drug was gradually washed out of the mucosal cells (Nissim, unpublished observations). These findings, and others previously reported, on the mode of action of this drug made it clear that cetrimide combined with the enzyme or carrier concerned with the active transport of glucose, after passing through the first, phloridzin-sensitive, receptor[7]. It was thus envisaged early that labelled cetrimide might be used to isolate this second receptor, be it enzyme or carrier, but it was soon realized that cetrimide, being a cationic surfactant, combined easily with a large number of proteins. This fact indicated that the proposed method for identification might prove a rather difficult one technically.

Concurrently with the accumulation of data on the mode of action of cetrimide, evidence was gathered that many other substances which combined with protein in a non-specific or semi-specific manner possessed the property of inhibiting glucose absorption to a greater or lesser extent. Thus, earlier studies demonstrated that the anionic sodium lauryl sulphate, which has a similar affinity for binding protein generally, stimulated and reduced glucose absorption in appropriate doses just as cetrimide did[7]. Vital dyes, such as phenol red, and mercuric ions[9], are known to reduce glucose absorption, and both are protein-binding agents. Likewise, digitalis derivatives, which bind certain proteins with avidity, inhibit active sugar transport in frog intestine at concentrations of 10^{-7} (ref. 10). The multiplicity and variance of these protein-binding compounds strongly suggested some non-specific or partially specific mechanism.

The next important clue concerning the nature of the second glucose receptor resulted from attempts to understand the stimulation of glucose absorption with small doses of cetrimide and of sodium lauryl sulphate. Surface activity was excluded as a likely cause, for these stimulating concentrations produced marked inhibition when combined with small doses of phloridzin[7]. This fact therefore pointed to a mobile intracellular protein carrier as the second receptor effecting active glucose transport. Wilbrandt and Rosenberg[2], in an investigation of competitive and inhibitor mechanisms in carrier transport, described five possible models, only one of which is capable of producing stimulation with small doses of the inhibitor substance. The full expression for the velocity of transport (v) is[11]:

$$v = \frac{v_{max}\,(I' + 1 - S'_1S'_2)\dfrac{(S'_1 - S'_2)}{(S'_1+1)\,(S'_2+1)\,(S'_1+I'+1)\,(S'_2+I'+1)}}{} \qquad (1)$$

where S'_1 and S'_2 represent substrate concentration at the two aspects of the cell membrane, or two poles of the cell itself, divided by the respective K_m or dissociation constant for substance and carrier. I' represents the corresponding equilibrium value for the inhibitor drug, the concentration of which is assumed to be the same at the two termini of interaction. Stimulation of transport is obtained when $(I' + 1 - S'_1S'_2)$ is negative and inhibition when it is positive. As previously indicated[12], this second receptor would be a protein. Furthermore, it has to be mobile in order to be exposed to two different media in which the dissociation constant (K_m) would be different. Since such protein movement is unlikely to take place within the cell membrane, the second receptor or carrier would be intracellular. With the emergence of this definite hypothesis for the transport mechanism, it was decided to put it to the test. This was done by investigating the effects of chloroquine, thevetin and phloridzin at a wide range of concentrations. Chloroquine, an antimalarial drug, was chosen on account of its affinity for protein, for it gives 98 per cent binding in plasma[13]; furthermore, it has not apparently been tested previously for its effect on glucose absorption. Thevetin, a digitalis derivative, was shown by Csáky *et al.*[10] to be a potent inhibitor of intestinal glucose absorption in *Rana pipiens*, but has not

been examined in other species. Since phloridzin produced glucose reversal in the mouse but not in the rat, it appeared to block receptors 1 and 2 in the former, but only receptor 1 in the latter. Only combination with receptor 2 was likely to produce enhancement of glucose absorption, and the compound was therefore investigated at a full range of concentrations in both species.

Chloroquine phosphate was studied in male *C3H* mice, thevetin in male albino (*AG*-2) mice and phloridzin in male *C3H* mice and albino rats. Combinations of drugs were studied in *C3H* mice. In mice, 25 ml. of 0·2 per cent (w/v) of D-glucose, D,L-methionine and sodium butyrate in 0·9 per cent sodium chloride, containing the desired concentration of the drug or combination of drugs, was circulated for half an hour through the lumen of the small intestine as previously described[7]. In rats, 50 ml. of the same control solution with the required phloridzin concentration was circulated for 0·5 h. Only the glucose was estimated in these experiments, by a modification of the method of Haslewood and Strookman[14]. 10^{-3} Evans blue was examined in four *C3H* mice under parallel conditions.

Evans blue. Inhibition by 10^{-3} Evans blue was of the same order as that by 10^{-3} sodium lauryl sulphate. The mean percentage absorption of glucose in the four experiments was 25·0 ± 1·1 as compared with the control value of 34·6 ± 0·9 in 34 experiments ($P \simeq 10^{-3}$).

Chloroquine and thevetin. The experiments are summarized in Table 1. In Fig. 1 the new results are compared with those previously obtained with cetrimide and sodium lauryl sulphate[7]. There was evident stimulation of glucose absorption with both drugs, which showed maxima at 5×10^{-5} chloroquine phosphate ($P < 10^{-5}$) and 10^{-5} thevetin ($P < 10^{-3}$). The inhibitory effect of both drugs was moderate.

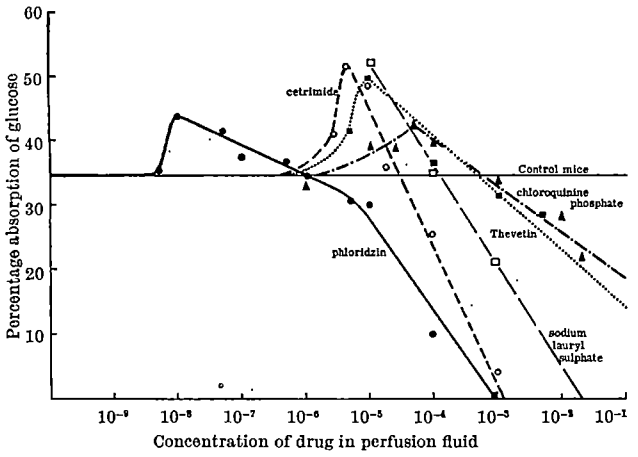

Fig. 1

Phloridzin. The results differed in the two species (Table 1, Figs. 1 and 2). In mice there was definite stimulation at concentrations of 10^{-8} ($P < 10^{-5}$) and of 5×10^{-8}. In rats there was only the random small variation about the control value with concentrations between 10^{-7} and 10^{-9}, so that no significant stimulant effect was obtained. Furthermore, the dose-response line was evidently composite in mice, with a sharp bend at about 10^{-6}, but straight in rats, right up to the point where it intersected the control line. There was marked inhibitory effect in both species with large concentrations.

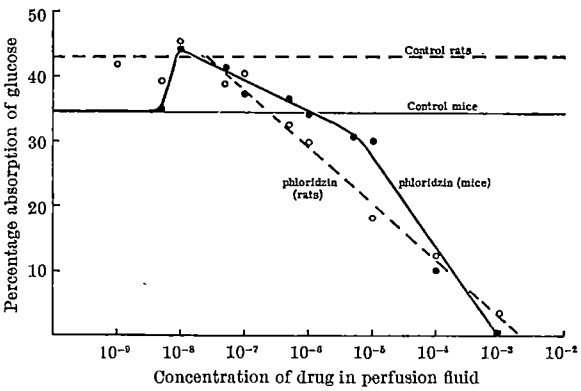

Fig. 2

Drug combinations. There was clear antagonism between phloridzin (10^{-4}) and chloroquine phosphate, increasing with the concentration of the latter drug ($P < 0{\cdot}01$). Thevetin also appeared to reduce the effect of phloridzin, but with the present number of experiments, P is just smaller than 0·1. The effect of 10^{-3} cetrimide was completely abolished with concentrations of 2×10^{-2} chloroquine phosphate ($P < 10^{-6}$). Curiously enough, the effect of chloroquine phosphate also seemed to be decreased by cetrimide ($P < 10^{-4}$), for the percentage absorption obtained with the mixture is significantly higher than with either drug alone.

The expected stimulation of glucose absorption has been substantiated, at very small P values, for both chloroquine and thevetin. Since neither compound is surface-active, the stimulation cannot be attributed to this physical effect. In the case of cetrimide and sodium lauryl sulphate, this was the first obvious mechanism which had to be excluded by other findings as mentioned before.

The striking stimulation of glucose absorption obtained with low concentrations of phloridzin was at first surprising, but when the significance of glucose reversal in the mouse was realized, namely, that phloridzin acted on the second receptor as well in this species, the result

became one of added interest. This composite action of phloridzin on the two receptors was evidently responsible for the sharp bend in the dose-response line in the mouse. The realization of this led to detailed testing of phloridzin in the rat, but neither stimulation nor reversal was ever obtained, and the dose-response line remained straight. Analysis of variance for the line between the doses 5×10^{-8} and 10^{-3} showed highly significant linear regression and non-significant deviation from regression.

The stimulation of glucose absorption in the mouse by these five totally different compounds, all of which are inhibitors of absorption at higher concentrations, leaves little doubt as to the mechanism in question. It is also clear that the drug-receptor combination cannot be very specific in nature. This view is strengthened by the antagonism between chloroquine and phloridzin and between chloroquine and cetrimide (Table 2), as it is also supported by the potentiation between phloridzin and cetrimide with regard to inhibition of α-D-glucosamine absorption when the concentration of the latter is low and their antagonism when the concentration is high[12]. The binding between protein and detergents, for example, is known to be a "totally unspecific reaction"[16]. This binding is through polar as well as non-polar groups and is dependent on *p*H. A protein of ovalbumin may bind up to 100 molecules of dodecylamine[15]. Evidently, cytoplasmic proteins can bind inorganic ions, various nutrient substances and numerous drugs. The results here indicate that these mobile proteins constitute the second receptor in the mechanism of absorption.

Table 2. Effect of Different Drug Combinations on Percentage Intestinal Absorption (Mean ± *S.E.*) of Glucose from Perfusion Fluid

Values represent mean of four experiments (except where indicated in brackets) in *C3H* mice

Drug concentration (w/v)	Percentage absorption	*P*
Phloridzin, 10^{-4}	10·0 ± 0·5	
Phloridzin, 10^{-4} + chloroquine, 10^{-4}	11·6 ± 1·6	
Phloridzin, 10^{-4} + chloroquine, 10^{-3}	12·6 ± 1·7	
Phloridzin, 10^{-4} + chloroquine, 2×10^{-3}	21·1 ± 2·6	< 0·01, compared with phloridzin, 10^{-4}
Phloridzin, 10^{-4} + thevetin, 10^{-3}	15·5 ± 2·7	< 0·1 > 0·05, compared with phloridzin, 10^{-4}
Cetrimide, 10^{-4}	25·2 ± 2·0 (14)	
Cetrimide, 10^{-3}	3·7 ± 1·5	
Cetrimide, 10^{-4} + chloroquine, 2×10^{-2}	22·2 ± 3·1	
Cetrimide, 10^{-3} + chloroquine, 2×10^{-2}	28·2 ± 0·4	< 10^{-6}, compared with cetrimide, 10^{-3} < 10^{-4}, compared with chloroquine, 2×10^{-2}

The foregoing results suggest therefore that, instead of a single and specific protein carrier for each nutrient, we have a spectrum of intracellular proteins—the intracellular plasma—with different affinities for nutrients as well as for drugs. The concept is supported by the fact that there is in intestinal absorption partial competition between different nutrients, for example, between glucose and amino-acids, and glucose and sodium butyrate[7,17]. This hypothesis of a spectrum of intracellular plasma fits in particularly well with the marked species differences and different activities of drugs previously reported[7]. The emerging model of the mucosal cell as an absorptive unit may be represented diagrammatically as in Fig. 3. The first receptor is on the inner aspect of the cell membrane. The association constant of the mobile second receptor must be greater at the mucosal pole of the cell, while the dissociation constant must be greater at the serosal pole. This greater affinity on the mucosal side between the intracellular proteins and actively transported substances must depend on different metabolic activities at the two opposite ends of the cell, namely, at *D* and *E*. These metabolic activities maintain an intracellular gradient in *p*H, redox potential, electrical potential or a combination of all three, and it is the maintenance of this gradient in the live cell which requires the expenditure of energy. When these energy-

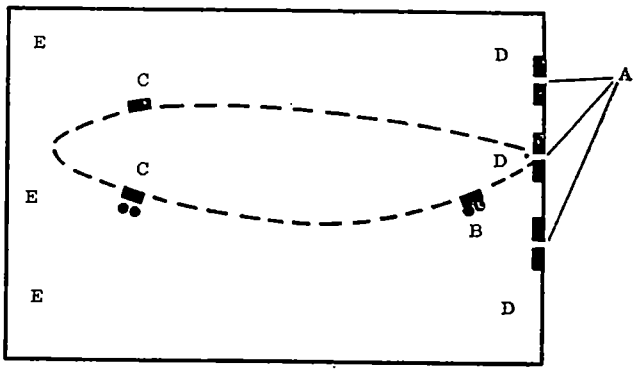

Fig. 3. Model of intestinal mucosal cell as an absorptive unit for nutrients, illustrating in particular the absorption of glucose. *A*, pore for sugar entry with first protein receptor on inner aspect of cell membrane—sensitive to phloridzin; *B*, second protein receptor, responsible for active transport, with molecules of sugar attached, at mucosal pole of cell—sensitive to cetrimide; *C*, second protein receptor, dissociated from molecules of sugar; *E* and *D*, sites of metabolic activities, at opposite poles of cell, responsible for *p*H or electrochemical gradient and giving different values for dissociation constant between nutrient and carrier protein

requiring metabolic processes are poisoned, for example, by 2,4-dinitrophenol, by iodoacetate or by other enzyme poisons, absorption is inhibited, for the second receptor cannot function properly with the same K_m value at the opposite poles of the cell. The theory explains all the odd assortments of facts which have accumulated so far, and which are too diverse to be enumerated here. It is pointed out, however, that the theory does not exclude relatively highly specific mechanisms for the absorption of some nutrients, for it is known that the absorption of cystine, for example, requires a special 'carrier', which is deficient in the congenital condition of cystinuria[18].

The concept advanced here of the mechanism of intestinal absorption may have wide applications in other fields of physiology and pharmacology, and may well result in the re-orientation of the whole of research on absorptive phenomena. It may also help in the detection of specific mechanisms, where they exist, more easily.

Finally, since cetrimide, at a concentration of 10^{-3}, completely paralyses the second receptor in the rabbit[7], so that glucose leaks into the intestinal lumen until its level equals that of the blood sugar, we may use data from these experiments to calculate the permeability constant (k) for glucose in this species. Using the well-known formula[1]:

$$k = \frac{V}{At} \cdot \ln \frac{C_{out} - C_{in}}{C_{out} - C'_{in}} \qquad (2)$$

where A represents surface area, V, volume of fluid, C_{out}, concentration of glucose outside the lumen, that is, in the blood, and C_{in} and C'_{in} the concentrations in the lumen before and after the interval of time t, we can determine k by substituting experimental values on the right-hand side of equation (2). The rise in glucose concentration per hour, in reversal experiments, shows an average of 40 mg or 0·01 per cent (C'_{in}) per sec—from zero (C_{in}). Taking C_{out} as equal to 200 mg per cent, $V = 250$ ml. and A as 6,000 cm²—after allowing for the 30-fold increase in surface area due to the convolutions in the brush-border or microvilli[3], we find, for $t = 1$ sec:

$$k = \frac{200}{6{,}000} \cdot \ln \frac{200 - 0}{200 - 199{\cdot}98} = 2{\cdot}295 \times 10^{-6} \text{ cm/sec} \qquad (3)$$

The energy required for preventing back diffusion is given by the formula[19]:

$$\text{Energy} = W = n_1 RT \cdot \ln(c_1/c_2) \qquad (4)$$

where n_1 represents the moles of substance transported in unit time, R, the gas constant, T, the absolute temperature, and c_1 and c_2 the final concentrations on the two sides of the membrane. Substituting in equation (4) from the same experimental data, and taking the total

weight of the rabbit small intestine as equal to 50 g, we obtain :

$$W = 43{\cdot}1 \text{ ergs/g/sec} \quad (5)$$

Parallel calculations for mice yield the same value for k, but the value of W is 77·7 ergs/g/sec, that is, nearly double the corresponding value in the rabbit. The explanation for the difference lies probably in the higher metabolic rate of smaller animals.

Reversal experiments with cetrimide in the rabbit and with cetrimide and phloridzin in the mouse have thus enabled us to determine the value of the permeability constant (k) for glucose *in vivo* for the first time. It is some 35 times smaller than the permeability constant for urea in red cells[1]. The calculated energy requirement for preventing glucose leakage in the mouse represents only about 1 per cent of the total energy expenditure by the intestinal mucosa, estimated at about 9,298 ergs/g/sec (ref. 20).

PATHOGENESIS OF THE POST-NEONATAL THYMECTOMY WASTING SYNDROME

By Dr. K. R. McINTIRE and Dr. S. SELL

AND

Dr. J. F. A. P. MILLER*

Chester Beatty Research Institute, Institute of Cancer Research, Royal Cancer Hospital, Fulham Road, London, S.W.3

DURING the past seventy years, several investigators have reported a cachectic or wasting disease following thymectomy in a variety of animal species including frogs[1], guinea-pigs[2], dogs[3] and goats[4]. It is difficult to determine whether this 'thymic cachexia' was the result of environmental factors, sepsis or actual lack of thymus tissue. Other investigations suggested that thymectomy in young animals did not lead to any alterations in growth or maturation[5]. Thymectomy, at or after 3 weeks of age, was performed in many strains of mice in work on experimental leukæmia. A review of these investigations has revealed no differences in growth, breeding behaviour, life-span, or susceptibility to common laboratory infections in thymectomized and control mice[6]. Some strains of mice thymectomized at birth grew normally for a time but then developed a syndrome characterized by marked wasting, lethargy, ruffled fur, hunched posture, sometimes diarrhœa and eventually death[7].

This condition closely resembles the syndromes seen in graft-versus-host reactions such as runt disease in mice injected at birth with allogeneic lymphoid cells[8], homologous disease in F_1 hybrid mice injected with parental lymphoid cells[9] and secondary disease in allogeneic[10], and even in some syngeneic[11], radiation chimæras. The earlier in life thymectomy was performed the higher the incidence of the wasting syndrome[12]. Thymectomy after 1 week of age was no longer associated with any significant incidence of this syndrome. About 50 per cent of wasted mice have been reported to show necrotic foci in the liver: granulomatous patches with aggregates of polymorphonuclear leucocytes, macrophages and giant cells[13,14]. These lesions have been associated with the presence of a hepatotrophic virus[14,15]. Other features of wasted mice are lack of subcutaneous fat, thinness of skin and intestinal walls, marked deficiency of small lymphocytes in blood and tissues[7,12,13], anæmia and proliferation of reticulo-endothelial elements in the liver, lymph nodes and spleen[16]. A small percentage of rats thymectomized at birth developed a similar wasting syndrome[17]. According to some investigators[18], thymectomy of male but not of female hamsters, as late as 2–4 weeks of age, was associated with the development of an essentially similar wasting syndrome.

The cause of the post-thymectomy wasting disease is obscure. Various theories can be proposed: infection, auto-immunity, loss of trephocytic lymphocytes, or loss of some thymus-specific growth-promoting factor. The fact that mice thymectomized at birth show immunological deficiencies[12], and are more susceptible to some effects of viral agents than sham-operated controls[14,19,20], suggests that their resistance to certain pathogens may be diminished. The fact that mortality in neonatally thymectomized mice was significantly reduced when they were "kept under nearly pathogen-free conditions"[21] and did not occur in "specific pathogen-free" mice[22] is in support of the infection hypothesis. Against this hypothesis can be cited the evidence that wasted mice were producing normal levels of γ-globulins and antibodies against certain standard antigens[23].

The similarities between graft-versus-host disease and the post-neonatal thymectomy wasting syndrome have been stressed[12]. These are: hyperplasia of the reticulo-endothelial system (proliferation of histiocytes, pyroninophilic cells, Kupffer cells), increased phagocytic activity, extensive extramedullary hæmopoiesis, diminished immunological competence, terminal lymphoid aplasia and trophic disturbances[16,24]. In graft-versus-host disease, pathological processes are initiated by immunologically competent cells with reactivities against xenotopes. After neonatal thymectomy, by analogy with graft-versus-host reactions, it might be postulated that immune, and

* This work was carried out while one of us (J. F. A. P. M.) was a recipient of an Eleanor Roosevelt International Fellowship at the National Cancer Institute.

therefore auto-immune, reactions are operating. In the absence of the thymus during the period of development of the lymphoid system, clones of cells with reactivities against idiotopes would develop unchecked, proliferate, and inflict damage on body constituents in the same manner that grafted lymphoid cells cause damage in the graft-versus-host reaction. The immunological incompetence of thymectomized animals would then be due to the 'immunological preoccupation' of the lymphoid cells with an auto-immune process. Against this hypothesis is the lack of any direct evidence in favour of the operation of auto-immune reactions, the failure to transfer the wasting syndrome to normal new-born hosts with lymphoid cells from neonatally thymectomized mice of the same strain[25], and the prevention of the syndrome by lymphoid cells from non-thymectomized donors of the same strain[26].

It was originally suggested by Carrell[27] that lymphocytes may be a mobile source of nutrients which promote growth and proliferation of other cells. Other investigators have supposed that the 'trephones' which lymphocytes might supply were nucleic acid fragments which were incorporated undegraded into the nucleic acids of proliferating cells[28]. The fact that failure to thrive is seen in conditions associated with deficiency of lymphocytes has led Loutit to postulate that the trophic disturbances seen in such conditions may be dependent on the loss of cells with trephocytic functions[29]. However, no direct evidence has been obtained to show that failure to thrive is dependent on a deficiency of any particular substance provided specifically by the lymphocyte.

The existence of specific thymus-growth promoting factors has been postulated by several investigators[30], but direct evidence for these is lacking.

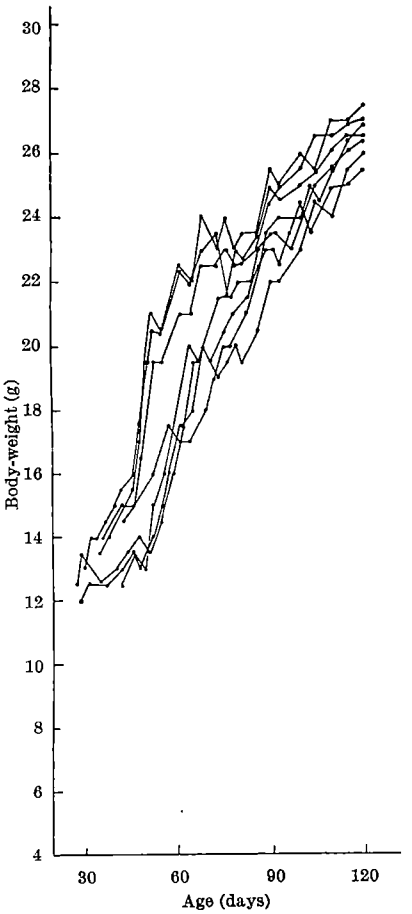

Fig. 1. Weight curves of conventional *C57BL* male mice sham or partially thymectomized at birth

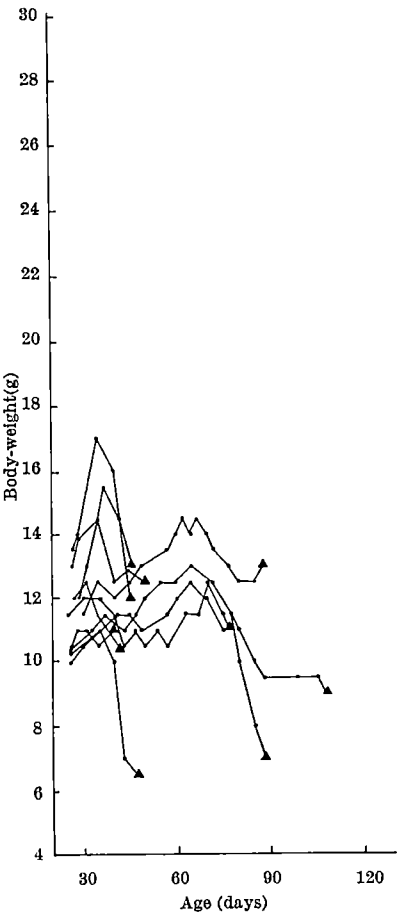

Fig. 2. Weight curves of conventional *C57BL* male mice completely thymectomized at birth. ▲, death from wasting disease

In order to determine whether infection plays a part in the pathogenesis of the post-neonatal thymectomy wasting syndrome, investigations were made on one highly inbred strain of mice under three environmental conditions: (1) conventional mice raised under ordinary laboratory conditions; (2) low pathogen mice originally obtained from germ-free mice and raised outside the germ-free environment, but isolated from all other mouse stocks; and (3) germ-free mice. All the mice were derived originally from the highly inbred *C57BL/Ka* strain maintained at the National Institutes of Health. Another highly inbred strain available in the germ-free environment was derived from the *BALB/c/An* line maintained in the same Institute.

In one experiment, *C57BL* mice of all three groups were thymectomized at birth by a method similar to that used for adult mice[31]. Body-weights were taken weekly and skin grafts from *BALB/c* mice were performed in some of the mice at 4–8 weeks of age. Controls were sham-operated at birth. Mice were killed and autopsied at appropriate periods and sections of thymus area, spleen, lymph nodes, liver, kidneys and ileum were fixed in Tellyesniczky's fluid and stained with hæmatoxylin and eosin.

There was a striking difference between the growth curves of conventional germ-free and low pathogen *C57BL* mice when thymectomized within 24 h of birth. More than 90 per cent of the conventional mice wasted between 5 and 10 weeks, whereas the germ-free and low pathogen mice showed no significant weight loss and no difference in size from untreated and partially thymectomized litter-mates. Individual weight curves of some of the mice in the various groups are shown in Figs. 1–7. The growth rates of an additional 49 completely thymectom-

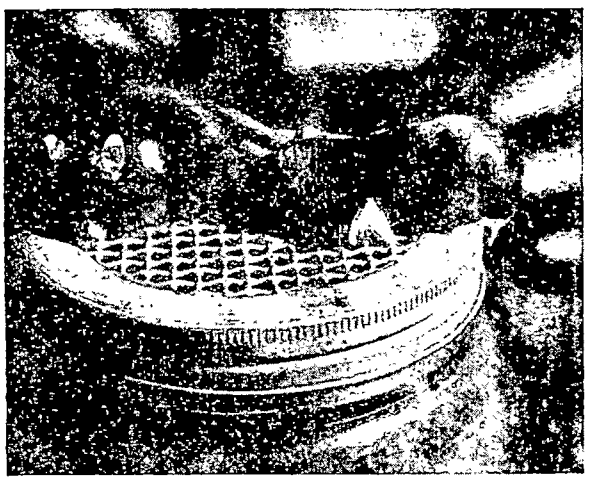

Fig. 8. Germ-free *C57BL* mice, 3 months of age, thymectomized at birth and bearing *BALB/c* skin grafts

ized germ-free and low pathogen mice are not shown in the figures: none of these 49 mice showed evidence of wasting at any time. Examination of the tissues of completely thymoctomized germ-free mice showed only a depletion of lymphocytes which was comparable with that seen in untreated germ-free mice. For skin grafting the only germ-free mouse strain available as donor was *BALB/c*, which differs from *C57BL* at the strong histocompatibility locus, *H-2*. None of the sham-operated mice showed prolongation of survival time of the graft, while 5 out of 20 of the thymectomized mice accepted the skin, which grew luxuriant tufts of hair (Table 1 and Fig. 8).

In another experiment an intraperitoneal injection of approximately 5×10^6 *BALB/c* and *C57BL* spleen cells were given to *C57BL* and *BALB/c* mice, respectively, on the day of birth and the growth of these mice was compared with that of non-injected litter-mate controls. One group was allowed to survive for longevity investigations and another group was killed at 12 days for estimation of organ weights and histology. In the case of *C57BL* recipients the body-weights of the injected conventional and germ-free mice were less than those of non-injected litter-mate controls (Fig. 9 and Table 2), and the mortality was very low in both groups. In contrast, the mortality of injected germ-free and conventional *BALB/c* mice was high: all the animals became severely runted by 11 days (Fig. 10) and 82 per cent of the germ-free and 94 per cent of the conventional mice had died by 18 days (Fig. 11).

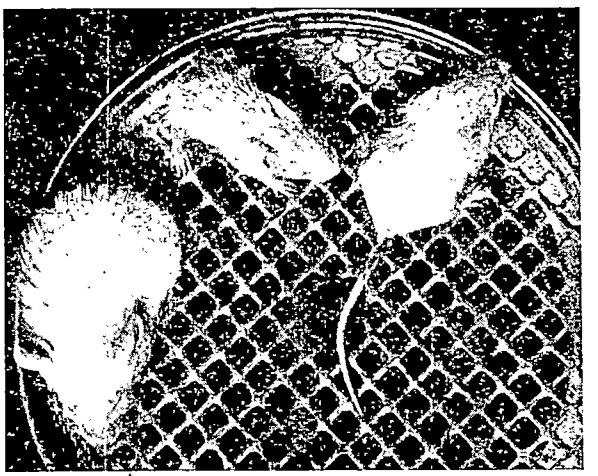

Fig. 10. Three-week-old germ-free *BALB/c* mice. The two runted mice were inoculated at birth with spleen cells from adult germ-free *C57BL* mice

Table 1. SURVIVAL OF *BALB/c* (GERM-FREE) SKIN GRAFTS ON GERM-FREE *C57BL* MICE THYMECTOMIZED AT BIRTH

Treatment at birth	No. of mice	No. of mice showing skin graft survival for: < 20 days	> 20 days
Sham thymectomy	10	10	
Total thymectomy	20	15	5*

*All grafts accepted for longer than 20 days grew luxuriant tufts of hair, and 4 of 5 were still healthy at the end of 50 days.

These results tend to rule out the absence of thymus-specific growth-promoting factors, the lack of trephocytes or the operation of auto-immune clones as primary factors in the pathogenesis of the post-neonatal thymectomy wasting syndrome. They do not exclude the possibility that some of these factors may operate as accessory factors. For example, in conventional thymectomized mice, an auto-immune process could still operate, but it may be secondary to cell destruction initiated by such agents as bacteria or their products, or viruses. The release of tissue breakdown products as a result of cell damage has been shown to produce an auto-antibody response[33]. The primary factor in the pathogenesis of the post-neonatal thymectomy wasting syndrome thus appears to be an environmental factor, presumably an infectious agent (or its product) to which only neonatally thymectomized mice, because of their diminished immunological capacity, are susceptible.

* Average of 5 mice per group.

The results of the first experiment clearly show that wasting did not occur after neonatal thymectomy in germ-free or low pathogen *C57BL* mice in contrast to conventional mice of the same stock. The fact that some germ-free *C57BL* mice were incapable of rejecting skin from *H-2* incompatible *BALB/c* donor mice indicates that immunological incompetence is a direct result of neonatal thymectomy and not secondary to either an infectious process or to whatever produces the wasting syndrome. It is known that the lymphoid tissues of animals kept in the germ-free state are not well populated with lymphocytes[32] so that thymectomy under these conditions may be expected to have little or no effect on such a population. This was indeed the case, as practically no difference was seen between the tissues of unchallenged thymectomized germ-free mice and their sham-operated litter-mate controls. Liver lesions, necrotic foci in lymphoid tissues, and splenomegaly were never observed in any of the killed germ-free *C57BL* thymectomized mice. On the other hand, evidence of graft-versus-host reactions developed in both conventional and germ-free *C57BL* and *BALB/c* mice inoculated at birth with adult *BALB/c* or *C57BL* spleen cells, respectively. This indicates that anti-host immune reactions can operate and produce runt disease in the germ-free environment. The low mortality of injected *C57BL* mice suggests that these mice may have developed, as early as the time of birth, some capacity for reacting against cells with foreign histocompatibility antigens. If this were true, it would explain why 75 per cent of neonatally thymectomized *C57BL* mice could reject *BALB/c* skin grafts.

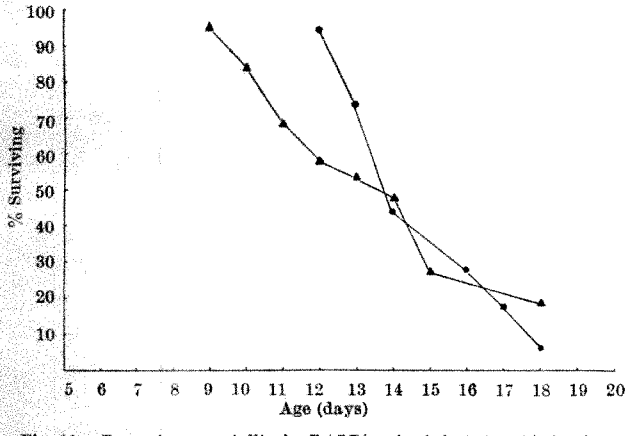

Fig. 11. Percentage mortality in *BALB/c* mice injected at birth with *C57BL* spleen cells. ●, conventional mice (18 mice); ▲, germ-free mice (19 mice)

FAT-SOLUBLE VITAMINS AND BIOLOGICAL MEMBRANES

By Dr. J. A. LUCY* and J. T. DINGLE*

Strangeways Research Laboratory, Cambridge

PAUL KARRER, who elucidated the chemical structure of vitamin A more than thirty years ago, remarked in 1960 (ref. 1): "We are fairly well informed about the physiological functions of the water-soluble vitamins because they are parts of enzymes, the reactions of which are pretty well known. On the other hand, we have very little information about the biological role of the fat-soluble vitamins. This is true also for vitamin A". Evidence has accumulated in this Laboratory during the past few years that vitamin A, when added in excess to biological systems, acts on the membranes of cells and their organelles. Recently, it has been found that vitamin A alcohol is also able to penetrate and expand a monolayer of lecithin-cholesterol at an air–water interface[2]. Considerable molecular specificity was observed in the experiments with monolayers; the anhydro and hydrogenated forms of the vitamin, which are biologically inactive, were much less surface active than vitamin A alcohol. It was suggested, therefore, that ability to penetrate lipid films might be the basis for the molecular specificity observed in many of the biological actions of vitamin A.

Penetration of lipoprotein membranes by excess of vitamin A alcohol frequently leads to a disruption of their structure. Since the molecular specificity for lysis of rabbit erythrocytes by compounds in the vitamin A series is similar to that for the prevention of vitamin A deficiency, the working hypothesis was put forward that the site of action of vitamin A is at the lipoprotein membranes of cells and their organelles[3]. It was also suggested that the role of the vitamin within membranes might be to control permeability and that membranes therefore become excessively unstable in the presence of excess of vitamin A.

Degradation of the matrix of embryonic cartilage provides an example of extensive secondary changes resulting from alterations in the properties of membranes caused by vitamin A[4–6]. Thus, release of hydrolytic enzymes from lysosomes by the action of the vitamin is responsible for many of the changes observed in this tissue[7–9]. Alterations in metabolism[5] which occur in the presence of excess of vitamin A may be associated with the swelling action of the vitamin on mitochondria[10]. The electron microscope has revealed damage to the plasma membrane, and also to the membranes of mitochondria, the endoplasmic reticulum and the nucleus of rat dermal fibroblasts treated with vitamin A alcohol in buffered saline[11,12]. Changes in metabolism and alterations in the membrane-bound structures of these cells have also been observed during cultivation *in vitro* with excess of the vitamin[13], while embryonic chick skin cultured in the presence of excess of vitamin A shows alterations of mitochondrial structure in epidermal cells[14].

In this article, it is reported that a number of isoprenoid compounds, including certain derivatives of vitamins E and K, stabilize lipoprotein membranes against rapid disruption by the presence of an excess of vitamin A alcohol. This finding, and other observations on the membrane-active properties of vitamin A, are discussed in relation to some suggested biochemical roles for vitamin A and other fat-soluble vitamins within the lipid moieties of biological membranes.

Inhibition of Vitamin A-induced Hæmolysis

Treatment of rabbit erythrocytes *in vitro* (1 in 40 suspension, v/v) with vitamin A alcohol[3] (10–20 μg/ml.) causes large indentations in the surface of the cells; vacuoles are then formed from the indentations by a process that resembles micropinocytosis[15]. Afterwards, the cells become spherical and lose hæmoglobin as breaks appear in the membranes. After 15 min at 37° C, most of the cells are lysed (Fig. 1*a*). In a preliminary communication, it was reported that the instability of red cell membranes produced by excess of vitamin A alcohol is largely prevented by DL-α-tocopheryl acetate[16]; mitochondrial swelling caused by vitamin A alcohol is similarly inhibited. When erythrocytes are incubated with both vitamin A alcohol (15 μg/ml.) and DL-α-tocopheryl acetate (50 μg/ml.), the sequence of changes in shape is similar to that seen with vitamin A alone (Fig. 1*b*). After 15 min, however, the cells are still intact though they contain vacuoles as a result of the initial expansions of the cell surface (Fig. 1*c*). Very few ghosts are present under these conditions. Cells treated with α-tocopheryl acetate alone (50 μg/ml.) resemble those treated with solvent (1 per cent ethanol) except that the cells tend to adhere to one another (Fig. 1*d*). It may be concluded that vitamin A alcohol penetrates the erythrocyte membrane both in the presence and absence of α-tocopheryl acetate, but that α-tocopheryl acetate prevents the subsequent rapid rupturing of the cell membrane that occurs with excess vitamin A alcohol alone. This stabilizing action of vitamin E may be related to its action in reducing the instability of a monolayer of lecithin and cholesterol containing a high proportion of vitamin A alcohol[17]. α-Tocopheryl acetate does not prevent penetration by vitamin A alcohol of the lipid monolayer, but its presence inhibits the subsequent slow fall in surface pressure[2].

The disruptive action of vitamin A alcohol on erythrocytes, lysosomes and mitochondria is highly temperature-dependent[3,7,10]. The inability of the vitamin to disrupt membranes in the cold may be due partly to a slower penetration of lipoprotein membranes by vitamin A alcohol at low temperatures. In experiments with lipid monolayers, marked isopiezic expansion was produced by vitamin A alcohol at and above 22° C, while at 13° C penetration and expansion of the lipid film were poor[2]. Electron micrographs of erythrocytes treated with vitamin A alcohol at 8° C for 15 min, however, reveal vacuoles within the cells, indicating that penetration of the cell membrane has occurred in the cold without causing hæmolysis (Fig. 1*e*). This expansion of the cell membrane and vacuole formation observed at 8° C closely resembles the action of vitamin A alcohol at 37° C when α-tocopheryl acetate is present, as may be seen from a comparison of Figs. 1*e* and 1*c*. It is interesting, therefore, that monolayers of lecithin-cholesterol penetrated by

vitamin A alcohol at the relatively low temperature of 13° C resembled those penetrated in the presence of α-tocopheryl acetate at room temperature and were stable for at least 15 min. Inhibition of lysis by vitamin E may thus be related to the inhibition associated with keeping the cells cold.

Although α-tocopheryl acetate inhibits loss of hæmoglobin caused by vitamin A alcohol during a 15-min period at 37° C, a significant loss of potassium still occurs. This leakage of potassium would be expected to cause complete lysis eventually, owing to the entry of water into the erythrocytes; longer incubation of the cells with α-tocopheryl acetate and vitamin A alcohol in fact produces hæmolysis. After 2 h, all the potassium has been released and loss of hæmoglobin is extensive (Fig. 2). Such relatively slow lysis may result from very small leaks in the membrane rather than from the comparatively large breaks seen both in the membranes of erythrocytes[15] (Fig. 1*a*) and in fibroblasts[11,12], treated with vitamin A alcohol alone. A possible mechanism for the production of these small holes in the membrane is discussed later.

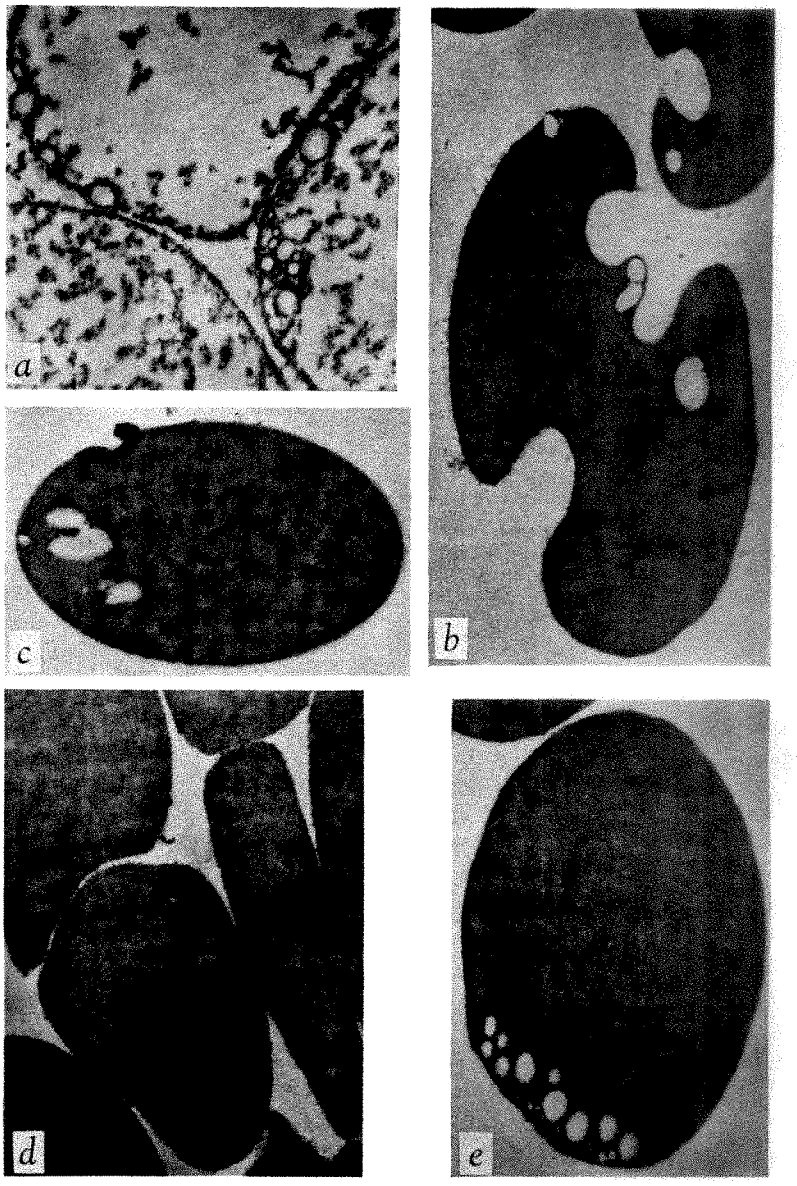

Fig. 1. Electron micrographs of thin sections of rabbit erythrocytes. Experimental procedures were as previously described[3,15]. (*a*) Ghosts formed on incubating cells with vitamin A alcohol (15 μg/ml.) for 15 min at 37° C. (*b*) At 25° C, indentations are produced in the cells 30 sec after addition to vitamin A alcohol (15 μg/ml.) and DL-α-tocopheryl acetate (50 μg/ml.). (*c*) An intact cell containing vacuoles after 15 min at 37° C with vitamin A alcohol (15 μg/ml.) and DL-α-tocopheryl acetate (50 μg/ml.). (*d*) Cells treated with DL-α-tocopheryl acetate (50 μg/ml.) for 15 min at 37° C. (*e*) An intact cell containing vacuoles after 15 min at 8° C with vitamin A alcohol (15 μg/ml.). All micrographs are × *c.* 14,500

Molecular Specificity for Inhibition of Lysis

It has been pointed out by Vasington *et al.* that although different ester derivatives of the tocopherols, including the phosphate, exhibit biological activity, this may be due to the liberation of free tocopherol by hydrolysis[18]. In order to investigate the relationships between molecular structure and activity, a number of different compounds were tested for their ability to inhibit lysis due to vitamin A alcohol.

DL-α-*Tocopherol.* The free alcohol form of vitamin E inhibited hæmolysis due to vitamin A alcohol (Table 1). It seems unlikely, however, that this is the active form when the acetate ester is used as inhibitor. Our standard suspension of rabbit erythrocytes was virtually unaffected by incubation at 37° C for 15 min with 500 μg/ml. of the ester, while extensive hæmolysis was produced by 200 μg/ml. of free α-tocopherol under the same conditions. Little hydrolysis of the acetate ester presumably occurs in this system.

D-α-*Tocopheryl acid succinate.* This compound, which is weakly hæmolytic, was active in inhibiting rapid lysis caused by vitamin A alcohol, although it was somewhat less effective than the acetate ester (Table 1).

Disodium DL-α-*tocopheryl phosphate.* The phosphate ester of α-tocopherol was strongly hæmolytic; extensive release of hæmoglobin occurred with 20 μg/ml., and lysis was virtually complete with 50 μg/ml. after 15 min incubation at 37° C. It is probably relevant that Rabinovitz and Boyer[19] have concluded that inhibition of the rat heart succinoxidase system by α-tocopheryl phosphate results from the ester behaving as an anion with a large non-polar group and that this inhibition is not necessarily related to the action of the phosphate as a vitamin.

Hydroquinone. It seemed possible that inhibition of lysis is associated with the antioxidant properties of vitamin E, and since hydroquinone, like the tocopherols, is soluble in ethanol this compound might be expected to inhibit rapid lysis due to vitamin A. No inhibition of lysis was observed, however, when quantities of up to 500 μg/ml. of hydroquinone were added simultaneously with vitamin A alcohol (15 μg/ml.). Hydroquinone was not lytic by itself under these conditions. The failure of hydroquinone to inhibit lysis due to vitamin A alcohol indicates that inhibition by the tocopherols may not be the result of neutralization of free radicals and the breaking of autoxidative chain reactions. This conclusion is supported by the fact that the acetate ester of α-tocopherol is particularly effective in inhibiting lysis, since the ester does not contain a hydroxyl group that can yield hydrogen and thereby neutralize free radicals.

Vitamins K_1, K_3 *and* K_5. Several authors have suggested that the reactivation by α-tocopherol, α-tocopheryl acetate and vitamin K_1 of succinic-cytochrome *c* reductase preparations that have been extracted with iso-octane is

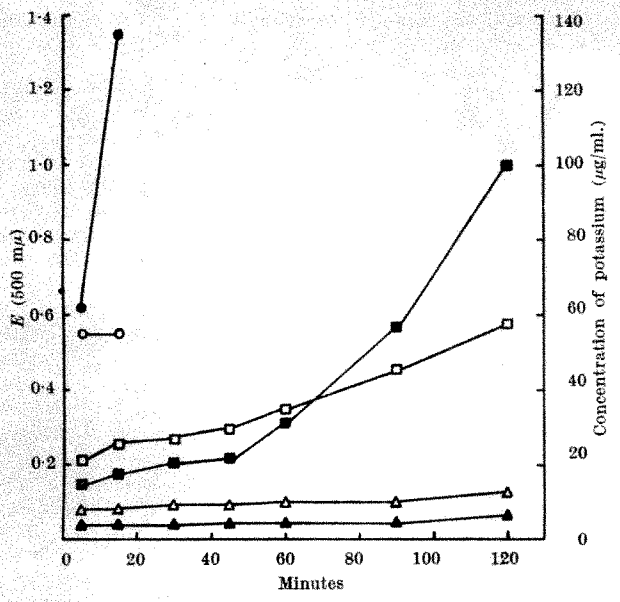

Fig. 2. Release of hæmoglobin and potassium at 37° C from the standard suspension[3] (1 : 40 v/v) of rabbit erythrocytes in sodium chloride solution (0·9 per cent). Closed symbols indicate release of hæmoglobin; ●, with vitamin A alcohol (15 μg/ml.); ■, with vitamin A alcohol (15 μg/ml.) and DL-α-tocopheryl acetate (50 μg/ml.); ▲, with ethanol (1 per cent). Open symbols indicate release of potassium; ○, with vitamin A alcohol (15 μg/ml.); □, with vitamin A alcohol (15 μg/ml.) and DL-α-tocopheryl acetate (50 μg/ml.), △, with ethanol (1 per cent)

a physico-chemical feature of the isoprenoid side-chains of these compounds rather than of any oxidation-reduction properties[20–23]. In view of this, and of the failure of hydroquinone to prevent lysis of erythrocytes by vitamin A alcohol, three compounds in the vitamin K series were tested. Vitamin K_1 inhibited lysis effectively, while menadione (vitamin K_3), which has the same quinone structure as vitamin K_1 but no isoprenoid side-chain, was inactive (Table 1) (cf. Crawford and Morrison[21]). 2-Methyl-4-amino-1-naphthol (vitamin K_5) was also inactive. Under the experimental conditions used, vitamins K_3 and K_5 caused only slight hæmolysis of erythrocytes when the compounds were tested by themselves. The inhibitory action of vitamin K_1 in vitamin A-induced lysis is interesting in the light of reports on interactions between vitamins A and K[24,25]. In particular, Walker *et al.*[26], in investigations on blood clotting, concluded that toxic excess of vitamin A induces a secondary deficiency of vitamin K. They also observed that massive doses of vitamin A caused an increase in plasma/cell ratio in the treated animals, which could sometimes be controlled by vitamin K.

Table 1. Percentage Inhibition of Vitamin A-induced Lysis

Compound	Concentration of inhibitor (μg/ml.)				
	10	25	50	100	200
DL-α-Tocopherol	65	78	78	—	—
DL-α-Tocopheryl acetate	52	84	87	—	—
D-α-Tocopheryl acid succinate	—	6	27	54	65
Disodium DL-α-tocopheryl phosphate	0	0	0	—	—
Hydroquinone	—	0	0	0	0
Vitamin K_1	38	44	72	86	—
Vitamin K_3	0	0	0	0	—
Vitamin K_5	0	0	0	0	—
Ubiquinone-30	77	93	86	88	87
Squalene	76	79	72	62	—
N,N^1-Diphenyl-*p*-phenylene diamine (DPPD)	0	0	0	—	—
Geraniol	11	5	0	0	0
Citral	7	7	4	0	0
Calciferol	5	3	8	0	0
L-Thyroxine, sodium salt	0	0	0	0	—

Rabbit erythrocytes were used as previously described[3]. Vitamin A alcohol was at 15 μg/ml., and the inhibitors were dissolved in ethanol (final concentration 1 per cent) with vitamin A. The phosphate ester of vitamin E in saline solution, and thyroxine in sodium carbonate solution (0·1 per cent w/v), were each added to the cells immediately before treatment with vitamin A. All tests were done at 37° C for 15 min[3].

Ubiquinone-30. This compound was very effective as an inhibitor of rapid lysis caused by vitamin A alcohol (Table 1), despite the fact that the antioxidant activity of ubiquinone-30 is much less than that of α-tocopherol[27,28].

Squalene and phytol. These two long-chain compounds, which have no activities as vitamins, are capable of reactivating preparations of succinic-cytochrome *c* reductase that have been extracted with iso-octane[20]. It is interesting, therefore, that both squalene (Table 1) and phytol inhibit lysis of erythrocytes by vitamin A alcohol. Phytol is itself hæmolytic at concentrations of 50–100 μg/ml., but at lower concentrations, which do not cause extensive lysis, it gave up to 60 per cent inhibition of lysis caused by vitamin A alcohol.

DPPD. The antioxidant, N,N^1-diphenyl-*p*-phenylene diamine (DPPD), which has some protective action against dialuric acid-induced hæmolysis[29], was tested for inhibition of lysis caused by vitamin A alcohol. No inhibition was observed (Table 1). The final concentration of ethanol was 2 per cent in this instance.

Other compounds. Geraniol, citral and calciferol were virtually inactive as inhibitors when tested in concentrations up to 250 μg/ml. Thyroxine, which is fully protective against both hæmolysis and lipid peroxidation caused by dialuric acid[30], was unable to inhibit lysis by vitamin A alcohol.

Structure and function. It is concluded from these experiments on the relationship of molecular structure to inhibition of lysis that inhibitory activity may be associated with the properties of the long isoprenoid chains of the active compounds.

Oxidation and Hæmolysis

Vitamin A is highly unsaturated and is easily oxidized[31,32]. Furthermore, interactions between vitamins A and E have been recognized for more than twenty years[33,34], and it is widely thought that vitamin E inhibits oxidative destruction of vitamin A. We have observed that, in the absence of vitamin E, the hæmolytic action of vitamin A alcohol is accelerated by the oxidizing agent, chloramine *T*, at a concentration of 0·015 per cent w/v (ref. 16); this concentration of oxidizing agent did not cause release of hæmoglobin in the absence of vitamin A alcohol. Rabbit erythrocytes were incubated with vitamin A alcohol (15 μg/ml.) for 2 min at 37° C, which is sufficient to enable the vitamin to penetrate the cell membrane, but not to cause release of hæmoglobin[15]. Chloramine *T* in saline solution was then added, and further incubation of the cells demonstrated the accelerating action of the oxidizing agent on vitamin A-induced lysis.

Rose and György[35,36] found that dialuric acid hæmolyses erythrocytes from vitamin E-deficient rats. There is a close relationship between hæmolysis induced by dialuric acid and lipid peroxidation, and agents that prevent hæmolysis also stop peroxide formation[30,37]. In the light of our experiments, it is interesting that both vitamin K_1 and phytol have some protective activity *in vitro* against hæmolysis by dialuric acid[29]. We have found that dialuric acid (0·02 per cent w/v) much accelerates the rate of lysis by vitamin A alcohol during a 15-min period at 37° C. Experiments with chloramine *T* and dialuric acid thus indicate that oxidation of the double bonds of vitamin A may be associated with the rapid hæmolysis that occurs at 37° C after penetration of lipoprotein membranes by the vitamin. Both these oxidizing agents, at the concentrations mentioned, can overcome the inhibition by α-tocopheryl acetate of lysis induced by vitamin A alcohol.

Since these experiments indicated that the disruptive action of vitamin A on membranes may involve oxidation of the vitamin, related experiments were done with oleic acid and the neutral detergent '*BRIJ* 35'. Vitamin E is known to inhibit the autoxidation *in vivo* of unsaturated fatty acids[38], and it was therefore interesting to find that the extensive lysis caused in 15 min at 37° C by oleic acid (30 μg/ml.) was progressively inhibited by increasing quantities of the acetate ester of α-tocopherol; 73 per cent inhibition of lysis was observed with a concentration of 200 μg/ml. of the vitamin. The dependence on temperature of lysis caused by oleic acid resembles that due to vitamin A alcohol, and lysis caused by oleic acid is also accelerated by chloramine *T*. In contrast to these observations, hæmolysis caused by '*BRIJ* 35' (100 μg/ml.) was unaffected by pretreatment of the cells with up to 1,000 μg/ml. of α-tocopheryl acetate. Chloramine *T* (0·015 per cent w/v) did not accelerate lysis by this concentration of detergent but, instead, inhibited it almost completely. Hæmolysis caused by the detergent has previously been shown to have different temperature characteristics from that caused by vitamin A alcohol[3].

Some Properties of Vitamin A within Membranes

It is conceivable that the functional presence of vitamin A within membranes may account for the broad syndrome of its biological actions. In this section, some properties of vitamin A in membranes are reported and their possible significance in the normal physiology of the vitamin is discussed.

The hypotonic release of hæmoglobin from a 1/200 (v/v) suspension of rabbit erythrocytes in dilute saline (0·6 per cent w/v), during incubation for 20 min at 23° C, is reduced by 60 per cent in the presence of 1 μg/ml. of vitamin A alcohol; loss of potassium is also diminished by the vitamin. Under these experimental conditions as little as 0·1 μg/ml. of vitamin A has a protective action, but the effect depends on the concentration of the cell suspension. Similar protection is given by vitamin A acid, vitamin A methyl ether and vitamin A aldehyde, while the palmitate ester is inactive. 3-Apo-β-carotenal, β-ionylidene acetaldehyde, β-ionone and citral have little or no effect on hypotonic hæmolysis. The stabilizing action of vitamin A alcohol, which is seen also in erythrocytes from rat, pig, chicken and human, can be prolonged either by the presence of α-tocopheryl acetate or by keeping the cells cold. The mechanism of this action of vitamin A alcohol is not clear, but one possibility is that stabilization towards hypotonic lysis is associated with expansion of the surface of the red cell by the vitamin[15], a process that may impart increased elasticity to the membrane.

Erythrocyte membranes that contain exogenous vitamin A alcohol, but are prevented from lysing rapidly by the presence of α-tocopheryl acetate or by a low temperature, have other demonstrably altered properties. The addition of serum albumin (0·5–1 per cent) to such cells causes virtually immediate and complete lysis which apparently results from combination of the added protein with molecules of vitamin A alcohol already present in the membrane; albumin that has been saturated with vitamin A alcohol is inactive[39]. Similarly, vitamin A alcohol has little effect on mitochondria at 3° C (ref. 10), but addition of albumin 2 min after adding the vitamin A alcohol causes immediate swelling. This lytic process is interesting in view of its similarity to lysis caused by the addition of calcium to erythrocytes previously treated with fluoride[40], and the possibility that it may provide a very simple test system for the study of immune hæmolysis[41]. At 25° C, lysis of red cells by the added albumin (1 per cent) occurs after only 1 min contact with the vitamin (10 μg/ml.), while at 1° C contact for about 8 min with the vitamin is needed before addition of the albumin produces a comparable degree of lysis.

This difference presumably reflects the slower penetration of vitamin A into the membrane at lower temperatures and appears to parallel the temperature dependence observed with penetration of lipid monolayers by vitamin A alcohol[2]. Calf thymus histone, bovine fibrinogen and human or bovine albumin, but not bovine γ-globulin, are effective in lysing vitamin A-sensitized cells. Any surface-active compound capable of penetrating membranes and subsequently binding strongly to protein may well cause lysis in this way, since '*BRIJ* 35' behaves like vitamin A alcohol when albumin, not previously saturated with the detergent, is added to red cells treated with '*BRIJ* 35' in the cold. The ability of a detergent to produce similar effects, however, does not detract from the need to consider these properties of vitamin A in relation to the vitamin's possible mechanisms of action, and it has been suggested that one of the physiological roles of vitamin A may be to stabilize membranes by acting as a cross-linking agent between lipid and protein since the vitamin is able to interact strongly with both molecular species[39].

It has recently been suggested that globular micelles of phospholipid, 40–50 Å in diameter, may be present in biological membranes under certain circumstances[42,43]. A theoretical micellar model for the lipids of biological membranes has also been discussed in which aqueous pores or holes, approximately 4 Å in radius, extend through the lipid layer of the membrane; such a micellar configuration might be in dynamic equilibrium with the bimolecular leaflet structure[44]. In the light of Haydon and Taylor's discussion[45], it has been suggested that a membrane containing a large quantity of vitamin A alcohol may have a high proportion of its structure in the more permeable, micellar form[44]. This suggestion would be consistent with the relatively slow leakage of potassium from erythrocytes incubated with vitamin A alcohol and α-tocopheryl acetate (Fig. 1). Release of hydrolytic enzymes from lysosomes by vitamin A might occur by a similar mechanism. α-Tocopheryl acetate has relatively little inhibitory action on the release of lysosomal enzymes by vitamin A[46], and enzyme release may not depend on oxidative damage to the membrane as appears to occur in vitamin A-treated erythrocytes and mitochondria, both of which contain hæmatin compounds that may catalyse oxidation. Even in the absence of oxidative changes, vitamin A might therefore exert a controlling influence on the permeability of cells and intracellular organelles under physiological conditions.

Discussion and Conclusions

Moore and Sharman[47] have recently shown that erythrocytes from rats fed with excess of vitamin A, like those from rats deficient in vitamin E, are easily hæmolysed by dialuric acid. In the present article, it is reported that vitamin A-induced lysis is accelerated *in vitro* by chloramine *T* and by dialuric acid; these observations suggest that lysis by vitamin A alcohol may at least in part be associated with oxidation of the vitamin. It has been reported that vitamin A behaves as a peroxidant of vegetable oils, and that antioxidants, including α-tocopherol, diminish peroxide formation[48].

The observations described here suggest that, under physiological conditions, damage to membranes by vitamin A may well be inhibited by the presence of suitable compounds such as certain other fat-soluble vitamins or the ubiquinones. α-Tocopheryl acetate does not prevent vitamin A alcohol from expanding the red cell membrane *in vitro*, and it appears that inhibition of lysis is associated with the prevention of rapid degradative changes which occur at 37° C after vitamin A

alcohol has penetrated the membrane. Since, however, the acetate ester of α-tocopherol is not an antioxidant in the usually accepted sense[49], and hydroquinone, menadione and vitamin K_5 do not inhibit lysis, the possibility that oxidation may not be involved in the degradative changes leading to hæmolysis cannot be categorically excluded at this stage.

Experiments on the molecular requirements for effective inhibition of rapid hæmolysis indicate that inhibition is a feature of compounds having a long isoprenoid chain. Thus, vitamin K_1, squalene and phytol are effective, but not menadione or vitamin K_5. It has been suggested that some kind of steric protection of the unsaturated chain of the vitamin A molecule by the chains of inhibitory compounds like vitamin K_1 may be concerned in this process[50], and it is conceivable that one of the functions of α-tocopheryl acetate, vitamin K_1, squalene and phytol in other systems[20,21], may also be the inhibition of the oxidation of unsaturated lipids. Cyanide, which under certain circumstances acts as an antioxidant, does not inhibit mitochondrial swelling caused by vitamin A alcohol[10], although swelling is prevented by α-tocopheryl acetate. This may provide a further example of apparent antioxidant activity of a compound possessing an isoprenoid chain since swelling of mitochondria induced by vitamin A has features in common with the swelling induced by ferrous ions, a phenomenon that has been shown to be associated with lipid peroxidation[51].

The red colour produced by the interaction of oxidized lipids, or their breakdown products, with thiobarbituric acid is commonly used as a measure of lipid peroxidation, although the exact mechanism of this reaction is not yet known[52,53]. In preliminary experiments, we have found that lipid peroxides, as measured by this procedure, may be concerned in lysis of erythrocytes by vitamin A alcohol, and that α-tocopheryl acetate decreases the formation of peroxides. The significance of these experiments is not clear, however, particularly since Green *et al.*[28] have concluded from their investigations on tissue homogenates that vitamin A must be considered as a factor in reducing lipid peroxidation as measured by the thiobarbituric acid test. Like them, we find it difficult to see why an unsaturated lipid such as vitamin A should protect against peroxidation. Nevertheless, it has been reported that vitamin A, but not vitamin K_1, inhibits mitochondrial swelling and lipid peroxidation caused by ferrous ions[51], and that both these vitamins inhibit swelling and peroxidation induced by ascorbate[54].

It seems possible that the physiological actions of fat-soluble vitamins may be concerned with the 'membrane-active' properties of these substances[12]. Vitamin D is important in maintaining the structure of mitochondria[55], in phospholipid metabolism[56], and in the release of calcium from mitochondria[57]; it is also capable of interacting with the membranes of Gram-positive bacteria as Kodicek[58] has shown. Willmer[59] has discussed many aspects of possible interactions of steroids, and of other molecules including vitamin A, with lipoprotein membranes. Vitamin E deficiency can lead to damage of the lipoprotein membranes of cells and their organelles, including lysosomes[60]. With regard to vitamin A, mitochondria from vitamin A-deficient animals are abnormally swollen[61], vitamin A drastically alters the morphology of certain viruses[62], and it has been suggested that the hypocholesterolæmic activity of vitamin A occurs before or during absorption of cholesterol through the intestinal wall[63]. These observations, the investigations on vitamins A, E and K reported here, and the related investigations discussed in this article, are thought to lend further support to the view that one biochemical site of action of vitamin A, and possibly of other fat soluble vitamins, is within membranes. Metabolic and structural changes occurring in vitamin deficiencies may therefore result from abnormalities in the structures and functions of the lipoprotein membranes of cells and their constituent organelles.

We thank Dame Honor B. Fell for her advice and Audrey M. Glauert for the electron micrographs. We also thank Miss J. Mizen and Mr. I. Armond for their assistance.

MATHEMATICAL EXPRESSION OF SEASONAL CHANGES IN SOIL ORGANIC MATTER

By Dr. J. S. RUSSELL

C.S.I.R.O. Division of Tropical Pastures, Cunningham Laboratory, Brisbane, Queensland

THERE are several concepts concerning changes in soil organic matter with time. On one hand there is the equilibrium concept which proposes that soils under a given land system eventually attain an equilibrium organic matter content. Under these conditions the amount of soil organic matter broken down is replaced by an equivalent amount of newly formed organic matter from plant and animal sources. Changes in organic matter content with time in this concept are considered as taking place from year to year.

On the other hand, considerable evidence has accumulated concerning seasonal changes in soil organic matter content[1]. These periodic changes occur during the year and even in situations which might be expected to be in equilibrium. They appear to be particularly pronounced under some forest conditions[2].

These two concepts of the dynamics of organic matter change are not necessarily mutually exclusive. It is conceivable that while over a year or growing season the net change in soil organic matter may be zero the march of decomposition and addition throughout the year may be quite different. Periodic or seasonal variation is thus theoretically possible even in situations where an annual equilibrium has been reached although the amplitude of such variation may vary in different environments.

Most deterministic equations proposed for expressing changes in soil organic matter have generally considered the equilibrium concept only. Seasonal variations have been ignored, and in most instances changes have been considered on a year-to-year basis only.

The differential equation most commonly used is:

$$\frac{dN}{dt} = -K_1N + K_2 \qquad (1)$$

where N represents soil organic nitrogen or carbon and K_1 and K_2 are decomposition and addition constants respectively. The solution to this equation is:

$$N_t = N_E - (N_E - N_0)\ \exp(-K_1t) \qquad (2)$$

where N_0, N_t and N_E represent the soil organic matter content initially, at time t and at equilibrium: t is generally expressed in years.

Though such an equation is comparatively simple to use it was considered[3] that a truer representation of such changes was to consider the decomposition and addition coefficients K_1 and K_2 as variable and time-dependent rather than constant. In this case equation (1) becomes :

$$\frac{dN}{dt} = -K_1(t)\,N + K_2(t) \qquad (3)$$

The general solution to this equation is :

$$N \exp\left(\int K_1(t)dt\right) = \int K_2(t) \exp\left(\int K_1(t)\,dt\right) dt + C \qquad (4)$$

When K_1 and K_2 are constant the solution to this equation is identical with (1).

In practice use of equation (4) presents problems. Soil organic matter changes are slow and while half-lives of less than 10 years have been calculated for some land systems in tropical regions[4] the changes appear slower in temperate regions and values in excess of 25 years are not uncommon[3]. (Half-life in this sense refers to the time taken for half the change from the original organic matter level to the new equilibrium level to occur.) Under these conditions of slow change it is difficult to estimate differences in the addition and decomposition coefficients except where detailed records are available over a long period.

However, equation (3) does provide a means of expressing seasonal or periodic change. Any property which varies periodically with time and whose magnitude or intensity can be measured or estimated can be represented by a trigonometric or Fourier series. Thus the change in the decomposition and addition coefficients throughout the year can be represented by Fourier series as follows :

$$K_1(t) = \tfrac{1}{2}\alpha_0 + \sum_{m=1}^{M} (\alpha_m \cos mt + \beta_m \sin mt) \qquad (5)$$

$$K_2(t) = \tfrac{1}{2}\gamma_0 + \sum_{m=1}^{M} (\gamma_m \cos mt + \delta_m \sin mt) \qquad (6)$$

For any given situation the relative series can be inserted in equation (3). This equation then becomes a first-order linear differential equation with periodic coefficients. That is :

$$\frac{dN}{dt} = -(\tfrac{1}{2}\alpha_0 + \alpha_1 \cos t + \beta_1 \sin t + \alpha_2 \cos 2t + \ldots.)\,N + (\tfrac{1}{2}\gamma_0 + \gamma_1 \cos t + \delta_1 \sin t + \gamma_2 \cos 2t + \ldots.) \qquad (7)$$

In this case t is expressed in radians and a year would be 2π radians, and although $K_1(t)$ and $K_2(t)$ may vary throughout the year their value from year to year is assumed to be constant.

Numerical solutions of equation (7) can be obtained by several methods. (I thank Dr. M. N. Oguztoreli, Department of Mathematics, University of Queensland, for assistance in the mathematical treatment.) If the initial condition is known an approximate solution can be obtained by Euler's method. This method lends itself to programming for a digital computer. Picard's method of successive integrations can also be used and a power series in the independent variable (t) obtained. However, unless the value M in the Fourier series is very small, integration beyond the second approximation presents difficulties due to the rapid increase in the number of trigonometric terms. This can be overcome to some extent by expressing the Fourier series as MacLaurin series and carrying out the repeated integrations in Picard's method with polynomials. This method is most accurate for small values of t. Where values over one year only are to be considered it may even be desirable to express $K_1(t)$ and $K_2(t)$ as polynomials (for example, by Lagrange's interpolation formula) rather than as Fourier series to reduce the computational difficulties in the successive integrations of equation (7) by Picard's method. Choice of method of numerical solution depends on whether a computer is available and also the period over which a solution is required.

In spite of the difficulties of numerical solution equation (7) is undoubtedly a more comprehensive representation of soil changes than equation (1). Equation (7) takes into account seasonal changes in soil organic matter during the year and also annual changes from year to year.

While such an equation should be of value in the field, it also provides a framework for testing soil organic matter changes experimentally under controlled environmental conditions, for example, in a 'phytotron'. The original equation (1) makes several assumptions concerning changes in soil organic matter with time. Where yearly changes only are considered, and half-lives of 25 years or more

occur, it is evident that the critical testing of this equation and its underlying assumptions, by experiment, is very difficult. The existence of periodic change in the decomposition and addition coefficients, however, does provide a means whereby the equation can be tested.

ELECTROENCEPHALOGRAPH DURING 'FEIGNED' SLEEP IN THE OPOSSUM

By Dr. ALLEN C. NORTON, ANTHONY V. BERAN and [the late] Prof. GEORGE A. MISRAHY

Developmental and Sensory Physiology Laboratory, Children's Hospital of Los Angeles, Sunset Boulevard, Los Angeles

THE opossum state, or 'feigned' sleep, is a well-known phenomenon in American folk-lore. Behaviourally it is a defence mechanism by which an opossum discourages a would-be attacker by pretending to be dead. When attacked, the opossum assumes a characteristic posture, curling itself into a round ball. The head is bent ventrally and the body curled; the limbs are slightly flexed and the muscles relatively flaccid. The animal remains motionless and is apparently insensitive to sensory stimulation. The most effective releaser for this response appears to be a dog, which will attack the opossum, grab it by the neck and shake it. Since the response represents such a unique behavioural mechanism it was of interest to investigate the EEG correlates of the behavioural state.

Fifteen adult opossums (*Didelphis virginiana*) were prepared with chronic, silver ball electrodes. The electrodes were placed on the dura resting over the frontal, parietal, temporal and occipital cortical regions, bilaterally; a ground lead was inserted into the sagittal crest of the skull. The electrodes were cemented to the skull with 'Grip' dental cement and led to a small (5 mm × 12 mm), 9-connector external plug. The connector plug was held to the skull with stainless steel wires and 'Acrylic' dental cement. Because of the rapid rate at which the opossum clears 'Nembutal'[1], it was necessary to insert a venous cannula in order to maintain anæsthesia during surgery. EEG recordings were taken from unrestrained, waking animals with an 8-channel Offner dynograph. Normal sleeping and waking records are shown in Fig. 1.

The most successful artificial technique for inducing the opossum state was found to be a combination of shaking and barking. An artificial dog jaw, resembling a large (2½ ft. long) pair of pliers, was prepared to grab the opossum by the neck and shake it vigorously. Dog barking, which had been pre-recorded on magnetic tape, was played through a loudspeaker near the animal while it was being shaken. When an opossum was attacked, he would typically enter a rage state, hissing, growling and attempting to attack the artificial jaw; autonomic reactions (salivation and defæcation) were marked. As the attack continued, the opossum would suddenly enter the opossum state, autonomic and bodily activity ceasing. When induced by these artificial means, the opossum state would last from a few sec to 2–3 min. Unlike the rapid onset of the opossum state, recovery from the state was gradual; the animal would slowly assume a normal posture and respond to external stimuli. The same sequence could often be repeated two or three times on the same day and on successive days.

Fig. 2 shows EEG tracings taken before, during and after the opossum state. Because of the rather vigorous shaking required to induce the opossum state, it was not possible to record the transition into the state. It will be noted that there is a slight flattening and increase in high frequencies during the opossum state, as compared with the control period before shaking. These changes should not be considered unique to the opossum state, however, since they continue afterwards when the animal's

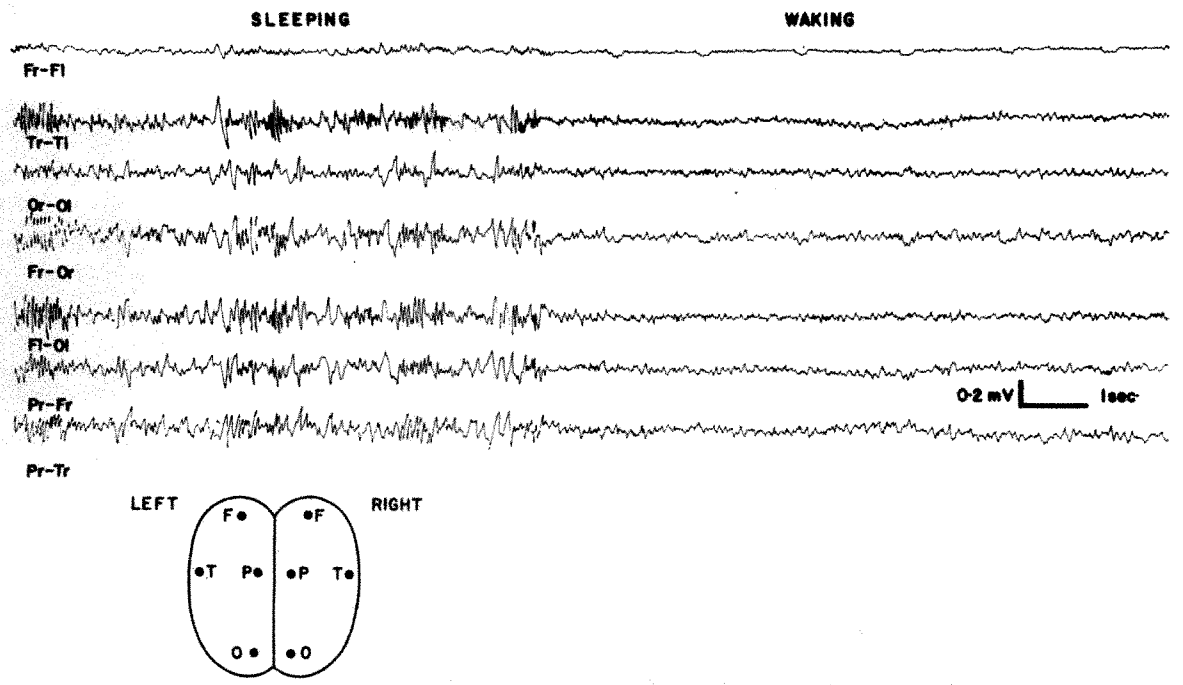

Fig. 1. Normal sleeping and waking EEG records in the opossum. Electrode placement lower left; time and voltage calibration lower right

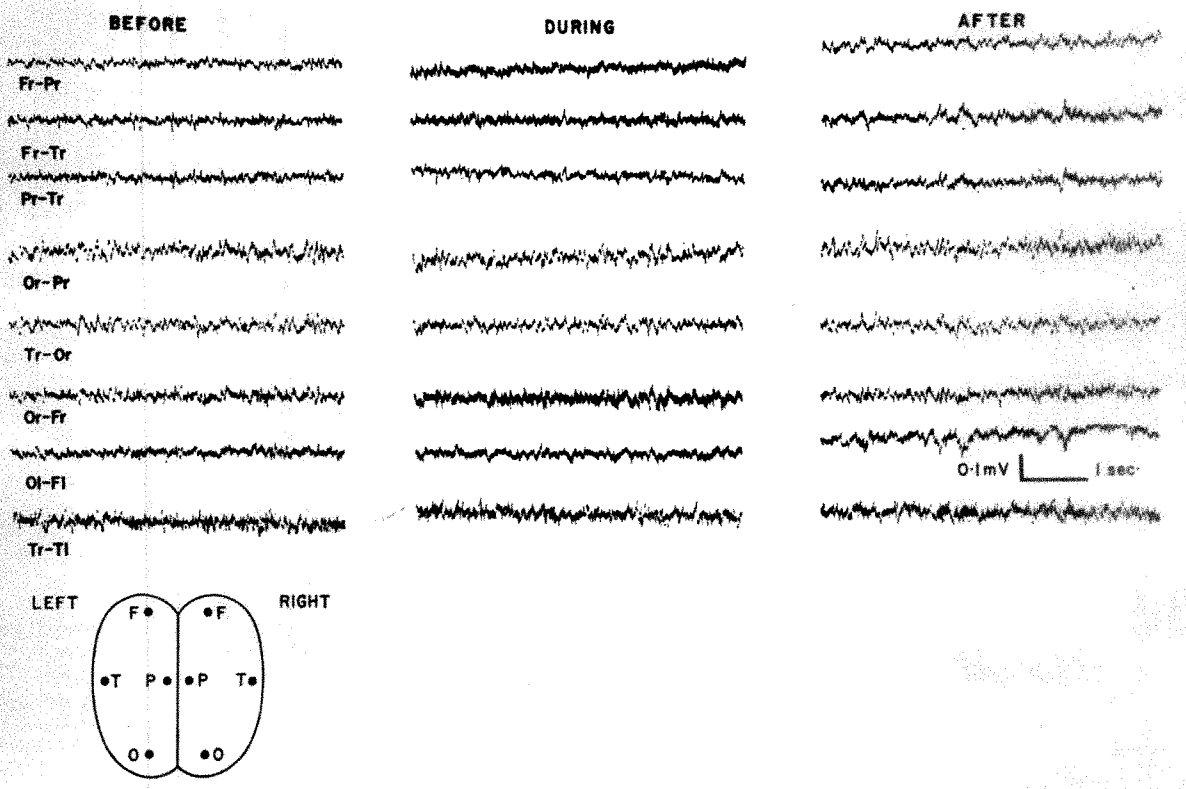

Fig. 2. EEG records before, during, and after an opossum state induced by artificial means. Electrode placement lower left; time and voltage calibration lower right

behaviour returns to normal, as seen in the third record. Such changes appear to reflect a more heightened arousal state induced by the attack situation. In animals which were highly aroused before entering the opossum state, changes before and during the state were not observed.

Because of the short time the animal would remain in the opossum state, and because of the failure to find EEG differences during the state, the question arose as to whether the state induced by our artificial methods was actually the opossum state familiar in folk-lore. In the course of the experiment it had been observed that although it was possible to induce the opossum state repetitively in the same animal, it became progressively more difficult to do so with each attempt. It seemed to hold generally that susceptibility to entering the opossum state decreased with increased contact with human experimenters. Thus, the following method was adopted to obtain more critical recordings during the opossum state.

Naïve opossums, newly brought into the laboratory, were isolated from human contact except for implantation of electrodes and daily feeding. After recovery from surgery and adaptation to the isolated living cages, they were subjected to the attack situation. In these critical experiments, the attacker was a real dog, supplied by a professional animal trainer. The dog would paw at the opossum, chase it into a corner, and then pick it up by the neck and shake it. The opossum was quickly shaken into the opossum state and would remain in the state up to 5–6 min. EEG recordings were taken during the opossum state and during recovery until the animal was behaving normally. Again no difference could be seen in the EEG between the opossum state and the subsequent control after recovery from the state. The EEG during the opossum state is that of a normal, waking, highly alert behavioural state. There is certainly no unique or unusual cortical activity during the state. It must be concluded that the folk-lore is correct; the animal is merely 'playing 'possum'[1].

SIMULTANEOUS OCCURRENCE OF HÆMOGLOBINS C AND LEPORE IN AN AFRO-AMERICAN

By Dr. HELEN M. RANNEY and ALAN S. JACOBS

Department of Medicine and the Heredity Unit, Albert Einstein College of Medicine and Bronx Municipal Hospital Center, Bronx 61, New York

In 1958 Gerald and Diamond[1] described hæmoglobin Lepore, an abnormal human hæmoglobin which migrated electrophoretically in the position of hæmoglobin S and comprised 5–12 per cent of the hæmoglobin of affected individuals. Hæmoglobin $Lepore_{Boston}$ and similar abnormal hæmoglobins described afterwards in Greek (hæmoglobin Pylos)[2], Italian[3] and Papuan[4] families have been associated with the clinical findings of thalassæmia minor. Hæmoglobin $Lepore_{Hollandia}$[4] and hæmoglobin Pylos[2] have each been encountered in the homozygous state : hæmoglobin A was absent in the hæmolysates of both homozygotes, and hæmoglobin A_2 was absent as well in the hæmolysate of the homozygote for hæmoglobin Pylos.

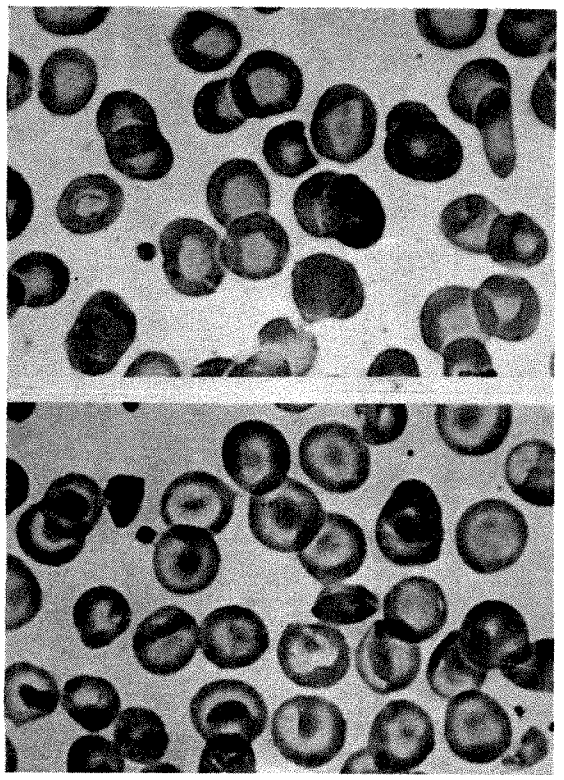

Fig. 1. *A*, Blood smear of II-2 (hæmoglobin Lepore$_{T.B.}$ trait). Hypochromia and stippled erythrocytes were noted. *B*, Blood smear of propositus III-5 (hæmoglobin Lepore$_{T.B.}$ and hæmoglobin C). Hypochromia, target cells and 'folded' red cells were observed

Baglioni[5] has provided an interesting hypothesis concerning the nature of hæmoglobin Lepore. He and Barnabas and Müller[6] found in hæmoglobin Lepore some tryptic peptides which appeared to be β-chain peptides, and others which resembled peptides of the δ-chains of hæmoglobin A_2. Recombination experiments[7] had indicated that the α-chain of hæmoglobin Lepore is identical with the α-chain of hæmoglobin A. Baglioni suggested that the remaining (non-α) chains, designated *x*, were composed in part of δ- and in part of β-chains as a result of unequal crossing over in the linked δ-β-locus.

This article is concerned with the presence of hæmoglobin Lepore in an American Negro family. One of the affected individuals had hæmoglobin Lepore in association with hæmoglobin C; in the other two individuals hæmoglobin Lepore occurred in association with hæmoglobin A. In accordance with recommendations concerning geographic designation[8], this hæmoglobin has been designated Lepore$_{\text{The Bronx}}$ (Lep.$_{T.B.}$).

Case report and family investigations. The propositus, a 17-year-old Negro high-school student, was first seen in January 1962, when she was referred for investigation of hæmoglobin C disease. This diagnosis had been made on the basis of a mild asymptomatic anæmia, the presence of target cells on blood smears, and a filter paper electrophoretic pattern which disclosed mostly hæmoglobin C. The patient was tall (6 ft.); she appeared healthy and the spleen was not palpable. Some laboratory data are listed in Table 1; hypochromic red cells and target cells were noted on blood smears (Fig. 1). Sickling preparations were negative and paper and agar electrophoresis disclosed hæmoglobin C and an increased amount of a minor hæmoglobin component, thought to be hæmoglobin F. When the hæmolysate was analysed by starch-gel electrophoresis[9] in borate buffer at *p*H 8·7, two hæmoglobin components both with mobilities intermediate between hæmoglobins C and A were observed (Fig. 2) in addition to the main C component. The components were quantified after electrophoretic separation on starch granules[10]: hæmoglobin C amounted to 80 per cent of the total hæmoglobin, hæmoglobin F (fastest component) to 6 per cent, and hæmoglobin Lepore to 14 per cent.

Family investigations (Fig. 3) were initiated, and the presence of a component resembling hæmoglobin Lepore was demonstrated in hæmolysates from the mother and from the maternal grandmother. The putative father had no abnormal hæmoglobin, and was of blood group AB. The mother's blood group was A, and the erythrocytes of the propositus were of blood group O. (The erythrocytes of the propositus were agglutinated by anti-H serum.) Therefore, on the basis of blood group investigations and of the hæmoglobin analyses, there appeared to be a lack of coincidence of the legal and the biological father. The latter was not identified; in all likelihood he had hæmoglobin C.

The hæmatological findings and hæmoglobin analysis of the mother, who was heterozygous for hæmoglobin Lepore$_{\text{The Bronx}}$, are included in Table 1. The maternal grandmother (Fig. 3, I-2) had received recent blood transfusions for anæmia secondary to metastatic carcinoma. The abnormal hæmoglobin was identified in her blood, but quantitative analyses were not carried out. The husband (Fig. 3, III-6) of the propositus had normal hæmoglobin, and their premature infant (Fig. 3, IV-5), born in April 1963, lived for only a few days. An umbilical cord sample obtained from the infant was found to contain mostly fœtal hæmoglobin together with a slow component which migrated in the position of hæmoglobin C and comprised 6 per cent of the total hæmoglobin.

The hæmoglobin of the propositus was analysed by starch-gel electrophoresis over a *p*H range of 8·0–9·0. While both minor components (F and Lepore) were readily identified, no component which had the mobility of hæmoglobin A could be identified in any of these gels.

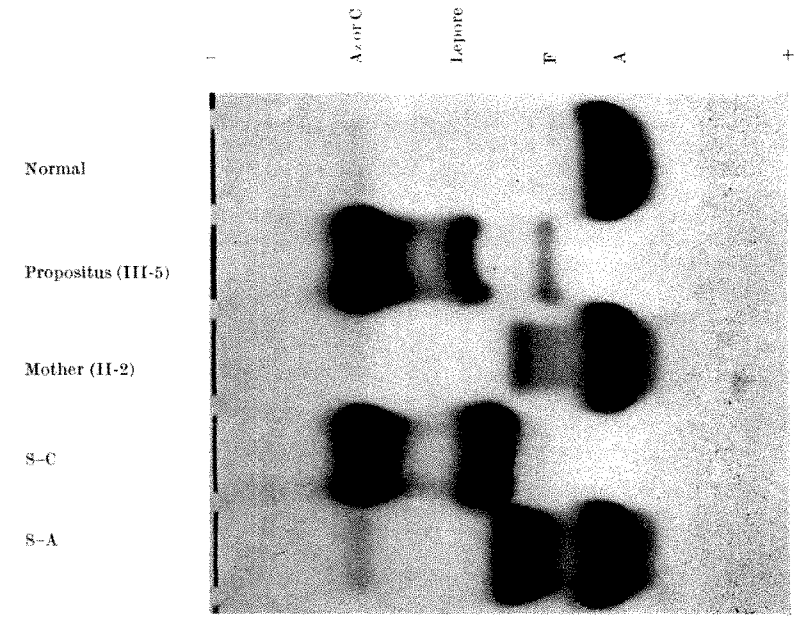

Fig. 2. Starch-gel electrophoresis (ref. 9) of hæmoglobins at *p*H 8·7. In hæmoglobin of propositus (III-5), 3 components (cathode to anode) C, Lepore and F, were observed. Note the greater anodal mobility of hæmoglobin Lepore in II-2, who had hæmoglobins A and Lepore. A similar alteration of mobility is noted in hæmoglobin S in a hæmolysate containing hæmoglobins A + S when compared with hæmolysate containing hæmoglobins C + S

Since the patient had hæmoglobin C, and her mother had not, the patient must have been heterozygous at the β-chain locus. The absence of hæmoglobin A in the patient's hæmolysate suggested that the other β-locus (that is, not β^C) in this patient did not determine the synthesis of normal β^A chains. If hæmoglobin $\text{Lepore}_{\text{The Bronx}}$ represented the product of a δ-β fusion on one chromosome, and a β^C gene was present on the opposite chromosome, no normal β-chains could be made, and hæmoglobin A would not be found.

Investigations of the structure of hæmoglobin $\text{Lepore}_{\text{The Bronx}}$. (1) *Recombination investigations.* Hybridization experiments were carried out at *p*H 4·7 by a modification of the method of Itano and Robinson[11]. Hæmoglobin Lep.$_{\text{T.B.}}$, isolated by two successive electrophoretic separations, was mixed with equal amounts of electrophoretically purified hæmoglobin S (a β-chain variant) or hæmoglobin $I_{\text{Burlington}}$ (an α-chain variant)[12]. Recombination, manifested by the identification of 4 hæmoglobin species after neutralization of the acidified mixture, occurred only in the mixture of hæmoglobin Lep.$_{\text{T.B.}}$ and hæmoglobin I. The abnormality in hæmoglobin Lep.$_{\text{T.B.}}$ must therefore reside in the non-α-chains:

$$\underset{\text{Hb I}}{\alpha_2^I\beta_2^A} + \underset{\text{Hb Lepore}}{\alpha_2^A x_2} \xrightarrow[\text{then neutralized}]{p\text{H } 4{\cdot}7} \underset{\text{Hb I}}{\alpha_2^I\beta_2^A} + \underset{\text{Hb A}}{\alpha_2^A\beta_2^*} + \underset{\text{doubly abnormal Lepore component}}{\alpha_2^I x_2} + \underset{\text{Hb Lepore component}}{\alpha_2^A x_2}$$

In experiments involving hæmoglobin Lep.$_{\text{T.B.}}$, and hæmoglobin I, hybridization was demonstrable only after the mixture of the hæmoglobins had remained at *p*H 4·7 for 72 h before neutralization. Demonstration of recombination of hæmoglobins containing α- and δ-chains has in general required prolonged acid treatment[13], although in hæmoglobins composed of α- and β-chains, recombination can be demonstrated after less than 4 h at *p*H 4·7.

(2) *Sedimentation investigations.* If hæmoglobin Lepore represented the combination of α^A polypeptide chains with a cross-over product of δ- and β-chains, examples of this abnormal hæmoglobin in which the cross-over product was significantly longer than the normal β- or δ-chain might be encountered. In that event, the molecular weight of the abnormal hæmoglobin might be larger than the molecular weight of normal human hæmoglobins A or A_2. Dr. Robin Briehl of the Department of Physiology determined the sedimentation constant of two purified samples of hæmoglobin Lep.$_{\text{T.B.}}$ in a Spinco model *E* analytical ultracentrifuge. In each determination, carried out at about 20° C and corrected to 20·0° C, the sedimentation constants (4·33 and 4·34 *S*) did not differ significantly from the values obtained for simultaneously purified hæmoglobin A (4·23 *S*) and hæmoglobin C (4·27 *S*).

(3) *'Fingerprinting' of hæmoglobin components.* Hæmoglobin components, C and $\text{Lepore}_{\text{The Bronx}}$, prepared from the hæmolysate of the propositus were 'fingerprinted' by the methods of Ingram[14] and Baglioni[15]. The hæmoglobin components were purified by chromatography on '*IRC*-50' resin columns with developer No. 2 of Allen *et al.*[16], and subsequent electrophoresis on starch granules. For isolation of hæmoglobin Lepore, two successive electrophoretic separations were carried out on the eluate from the '*IRC*' column. Electrophoresis of the tryptic digests of purified hæmoglobin components was carried out at *p*H 6·4 in pyridine–acetic acid–water[14], and ascending chromatography in the solvent mixtures utilized by Baglioni[5].

Fingerprints of hæmoglobin C isolated from the hæmolysates of the propositus appeared identical with fingerprints of hæmoglobin C published by Hunt and Ingram[17].

Three tryptic digests of samples of hæmoglobin Lep.$_{\text{T.B.}}$ were fingerprinted together with tryptic digests of hæmoglobin A and A_2. The analyses of the tryptic peptides are not completed; but observations on the fingerprints revealed 5 apparently significant findings: (1) Peptide A_2a, a δ-chain peptide (*Tp* δ XIII) (ref. 18) was absent in hæmoglobin Lep.$_{\text{T.B.}}$. (2) In the fingerprints in which good resolution of peptide 12 was obtained, it appeared to have an R_F comparable to that of peptide 12 of hæmoglobin A_2 rather than of hæmoglobin A. This observation was confirmed by ascending chromatography in *n*-butanol–acetic acid–water (3 : 1 : 1) of peptides 10–14 of hæmoglobins A, A_2, and Lep.$_{\text{T.B.}}$, eluted after one-dimensional ionophoresis[18]: the lowest tryptophan positive peptide of hæmoglobin Lep.$_{\text{T.B.}}$ and hæmoglobin A_2 were in corresponding positions. Peptide 12 thus resembled *Tp* δ II. (3) In hæmoglobin Lep.$_{\text{T.B.}}$ a peptide in the position of peptide 26 (an arginine-positive β-peptide of hæmoglobin A) was inconstantly present, but not

A.E.C.M. Heredity Unit. Kindred No. 23

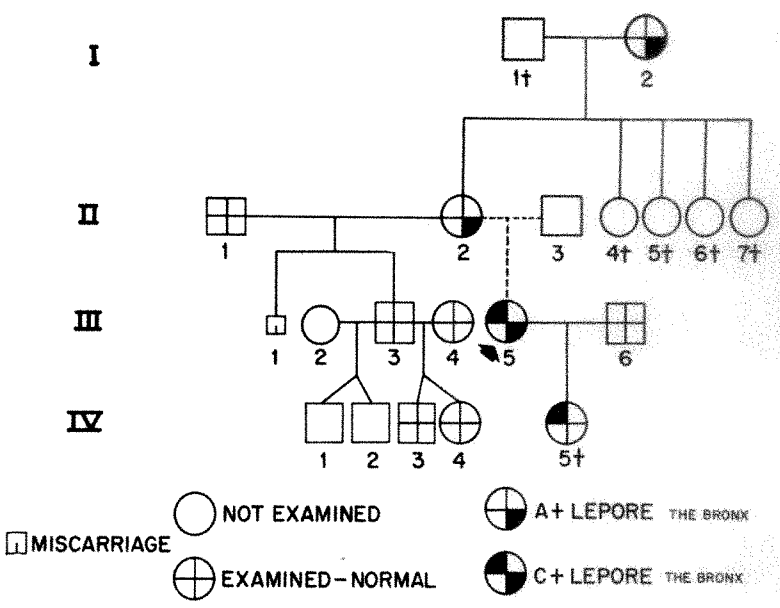

Fig. 3. No. IV-5 was a premature infant: examination of the cord blood showed small amounts of a component with the mobility of hæmoglobin C, together with hæmoglobins F and A. The amount of cord blood available was insufficient for fingerprinting

Table 1. Hæmatological Data and Hæmoglobin Analyses on 2 Subjects with Hæmoglobin $\text{Lepore}_{\text{The Bronx}}$

	Hb (g%)	Red blood cells ($\times 10^6$/mm³)	Reticulocytes (%)	Smear		Hæmoglobin analysis					
						Alkali resistance (F)%	Starch electrophoresis (ref. 10) % component eluted from starch				
				Targets	Hypochromia		A_2	C	Lepore	A	F
Propositus	10·7	5·3	2·2	+ + +	+ +	6	*	80	14	0	6
Mother	11·8	5·2	3·1	+	+ +	5	1	0	8	91	†

* Hæmoglobin A_2 not separated from hæmoglobin C. † Hæmoglobin F not separated from hæmoglobin A.

arginine-positive, in fingerprints prepared from the first tryptic digest. In collaboration with Dr. L. J. Reed, a second tryptic digest of hæmoglobin $Lep._{T.B.}$ was analysed and peptide 26 was consistently absent. It was therefore concluded that β *Tp* III (peptide 26) was absent in hæmoglobin $Lepore_{T.B.}$. The two remaining findings in the peptide maps of $Lepore_{T.B.}$ which were also present in $Lepore_{Boston}$ (ref. 5) were: (4) The R_F's of peptides 24 and 25 (β *Tp* V) were lower in hæmoglobin Lepore than in hæmoglobin A, and (5) the spot corresponding to peptide 5 (*Tp* β XIII or *Tp* δ XIV) was tyrosine-positive and sulphur-negative in hæmoglobin $Lepore_{T.B.}$. The last finding indicated that peptide 5 (*Tp* β XIII) resembled that of the β- rather than of the δ-chain. In summary, the fingerprints of hæmoglobin $Lepore_{T.B.}$ (prepared from hæmoglobin of an American Negro) contained no apparent differences from those of hæmoglobin $Lepore_{Boston}$ (prepared from hæmoglobin of a patient of Italian ancestry). In both $Lepore_{Boston}$ and $Lepore_{T.B.}$, tryptic peptides II, III and V resembled δ-chain peptides and tryptic peptides XII and XIII resembled the β-peptides.

Hæmoglobin $Lepore_{T.B.}$ resembled other examples of hæmoglobin Lepore in: (1) the amount of the component present; (2) the associated findings of thalassæmia; (3) the decrease in hæmoglobin A_2 in the presence of hæmoglobins Lepore and A.

(4) *Amino-acid analyses.* Amino-acid analysis of a 22-h hydrolysate of hæmoglobin $Lepore_{T.B.}$ was carried out on a Beckman amino-acid analyser. Isoleucine, found in hæmoglobin $Lepore_{Hollandia}$, was absent from hæmoglobin $Lepore_{T.B.}$. Unequal crossing-over might, as suggested by Nance[19], be a commonly occurring mechanism underlying the synthesis of protein variants. However, evidence for involvement of the γ-chain locus in hæmoglobin $Lep._{T.B.}$ was not obtained in our investigations.

Recently, the absence of hæmoglobin A was observed in two patients who were heterozygous for both hæmoglobin S and hæmoglobin Pylos[20]. The absence of hæmoglobin A in a subject heterozygous for both hæmoglobins C and Lepore is consistent with Baglioni's hypothesis that hæmoglobin Lepore results from crossing-over in the linked δ-β locus.

BEHAVIOUR IN EGGS AND TISSUE CULTURE OF THE INCLUSION BLENNORRHŒA (*LB*4) STRAIN OF THE TRACHOMA–INCLUSION CONJUNCTIVITIS VIRUS GROUP

By Dr. N. M. LARIN and J. D. TREHARNE
Biologicals Research Department, Pfizer Ltd., Sandwich, Kent

THE existence of a linear relationship between the amount of virus inoculated into the yolk sac and the average day of death of the embryo is now generally accepted for the psittacosis–LGV (PLGV) and the closely related trachoma–inclusion conjunctivitis (TRIC) virus groups. This relationship has been described in detail by Golub[1] for viruses of the PLGV group and by Jawetz and Hanna[2], Watkins[3] and by Reeve and Taverne[4] for viruses of the TRIC group. Another important observation was made by T'ang[5], who reported that the lethal action of the *TE*55 virus strain of trachoma for the embryo was increased on passage, and also that a steep rise in infectivity occurred between the tenth and fifteenth passage. Reeve and Taverne[4] have observed that some virus strains of the TRIC group changed their behaviour on passage in eggs, killing the embryos faster and acquiring also the capacity to form inclusions in HeLa cells. They explained these changes in growth characteristics by the emergence and subsequent selection of virus mutants.

The relationship between the reproductive capacity of TRIC viruses in tissue culture and their virulence for embryonated eggs poses many important questions; therefore it seemed desirable to conduct a comparative investigation of the behaviour in embryonated eggs and tissue culture of a virus strain of the TRIC group. The results of such an investigation are discussed in this article.

We used in this work the *LB*4 strain of inclusion blennorrhœa virus. This strain was described by Jones, Collier and Smith[6] and it was obtained in the third egg passage from the Medical Research Council Trachoma Unit, Lister Institute, London.

Many titrations of the *LB*4 strain at different egg passage levels have been carried out in eggs over a ten-day incubation period and in tissue culture; the results to be reported are representative of two years' investigation of this strain. At no time during experimental investigations of this strain were any other virus strains handled. Thus there was no possibility of contamination.

All egg passages were carried out using high concentrations of virus in the inoculum. This technique would seem to favour the chances of selecting out any mutations occurring in the virus population. *LB*4 did not produce inclusions in HeLa cells prior to the seventh egg passage, but beginning from the seventh, and on subsequent egg passages, the virus produced numerous inclusions in HeLa,

Table 1

Egg passage No.	Log_{10} ELD_{50}/ml. titres of 20% yolk sac suspensions of *LB*4 virus	Inclusion titre of 20% yolk sac suspensions of *LB*4 virus in HeLa cells, I.F.U./ml.
4	3·75	No inclusions
5	4·75	,,
6	5·25	,,
7	5·50	$5{\cdot}5 \times 10^5$
8	5·25	$5{\cdot}3 \times 10^5$
9	5·50	$2{\cdot}8 \times 10^5$
10	Not titrated	$1{\cdot}0 \times 10^6$
11	5·50	$3{\cdot}2 \times 10^5$
12	5·75	$4{\cdot}4 \times 10^5$

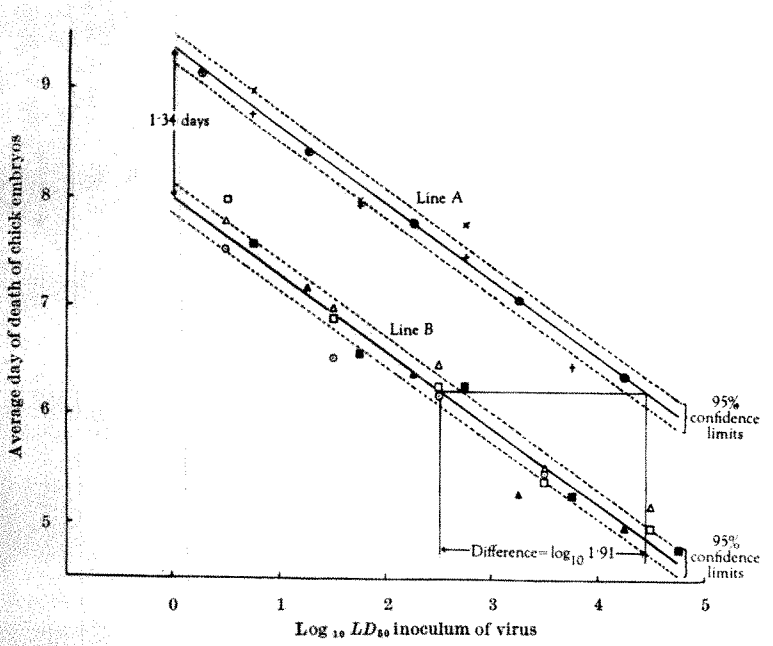

Fig. 1. Egg passage number: ×, 4; +, 5; ⊕, 6; △, 7; ▲, 8; ○, 9; □, 11; ■, 12

F.L. and *WI/38* cell systems; these were titrated by the method of Furness *et al.*[7]. Table 1 shows representative results obtained with 20 per cent yolk sac suspensions of *LB4* virus in HeLa cells. The ability to form inclusions in tissue culture was correlated with a steep increase in virulence of the virus for the chick embryo at the seventh egg passage as measured by the average day of death.

Fig. 1 shows that there is a linear relationship between the log concentration of virus in the inoculum and average day of death. A statistical analysis of these data revealed that this relationship was very similar at the fourth to sixth egg passages, and it could be represented by a straight line *A*. The linear relationship also held for the seventh to twelfth egg passages which could be represented by another straight line *B*. The slopes of *A* and *B* were not significantly different, and therefore they could be drawn as two parallel lines. The mean difference of the average day of death between the two lines *A* and *B* is 1·34 days with 95 per cent confidence limits of 1·21–1·47 days. This difference corresponds to an 81-times increase of virulence, that is, $\log_{10}$ 1·91 LD_{50}. Although the growth rate as estimated from the slopes of the *A* and *B* lines is similar, that is, 1·42 $\log_{10}$ LD_{50} per day, it is obvious that a steep increase of virus virulence for the chick embryos has occurred. However, there was no increase in the virus titres observed during the passages. Collier[8] noted that another inclusion blennorrhœa strain—*LB1*—lost its pathogenicity for the baboon conjunctiva after its eighth egg passage. We have not ascertained whether the changes described for *LB4* virus are associated with this characteristic.

In other experiments to be published elsewhere, we have observed that *LB4* virus pools before or after the seventh passage retained their immunogenic capacity, that is, when these virus pools were inoculated into baboons, the animals acquired immunity against a conjunctival challenge with homologous virus of the second egg passage.

The results of experiments just described show clearly that there was a relationship between the capacity of the *LB4* strain to form inclusions in tissue-culture cells and a steep increase in virulence for the chick embryo that has occurred at the seventh egg passage.

Since it is possible that several factors may have been responsible for this phenomenon, a reasonable interpretation of it would be as follows:

First, the third egg passage suspension of the *LB4* strain possibly contained a heterogeneous population of particles, some of high or low virulence and some uninfective for the egg embryo. In this context, the recorded average day of death for this strain may have depended on the ratio between particles of high and low virulence.

Secondly, the ability of this strain to form inclusions in tissue-culture cells may also depend on a ratio between particles of high and low virulence.

Finally, the highly virulent particles may have outgrown the ones of low virulence during the frequent consecutive passages in eggs, this resulting in a change of the ratio and consequently in an increase of the lethal action for the chick embryo and the capacity to form inclusions in tissue culture cells.

We thank Dr. L. H. Collier, Dr. W. A. Blyth and Dr. Janice Taverne of the Trachoma Unit, Lister Institute, London, for their advice and for kindly supplying us with the *LB4* strain. We also thank the Directors of Pfizer, Ltd., for permission to publish this communication.

MITOCHONDRIAL AND CYTOPLASMIC ENZYMES FOR THE REDUCTION OF FUMARATE TO SUCCINATE IN YEAST

By Dr. CRISTIANO ROSSI, JOSEPH HAUBER and Dr. THOMAS P. SINGER
Edsel B. Ford Institute for Medical Research, Henry Ford Hospital, Detroit

In 1937 Fischer and Eysenbach[1] proposed the existence of an enzyme, which they named fumaric hydrogenase (fumarate reductase in present-day terminology), which catalyses the reduction of fumarate to succinate but cannot function as a succinate dehydrogenase. This hypothesis was based on the observation that partially purified samples of Warburg's "old yellow enzyme" catalysed the oxidation of reduced dyes of low potential, such as leucodiethylsafranin, in the presence of fumarate but failed to oxidize succinate with methylene blue as electron acceptor. It should be mentioned that this investigation antedated by many years recognition of the fact that mitochondrial succinate dehydrogenase does not react directly with methylene blue, but reacts rapidly with *N*-alkylphenazonium dyes, such as phenazine methosulphate[2,3]. In a later paper, Fischer *et al.*[4] stated that their preparation was inactivated by dialysis and that the activity was restored by the addition of FAD. Isolation of the enzyme

from a reproducible starting material, such as fresh yeast, was apparently not undertaken.

The concept of a unidirectional fumarate reductase in anaerobic yeast was widely accepted and remained unquestioned until about 1956. During this period some investigators, in fact, believed that yeast cells were devoid of succinate dehydrogenase activity, even when grown aerobically[5], until their apparent lack of succinate oxidation by intact yeast cells was traced to a permeability problem[6,7].

Succinate dehydrogenase was isolated in this laboratory from yeast mitochondria in 1956 (refs. 8 and 9), and its properties were found to resemble those of the enzyme from mammalian tissues in most respects, including the fact that the action of the enzyme is readily reversible. The ratio of rates of succinate oxidation to fumarate reduction remained essentially constant during purification and on treatment with inhibitors and denaturing agents, and no evidence was found for the existence of a separate fumarate reductase in the mitochondria[9,10]. Since the fumarate reductase activity ascribable to the mitochondrial enzyme was several orders of magnitude higher than the activities reported by Fischer *et al.*[1,4], it seemed possible that the German workers had been dealing with differentially inactivated succinate dehydrogenase samples. This reasoning was based on the fact that several steps in the isolation of the "old yellow enzyme" (the starting material for Fischer's preparation) would greatly inactivate mitochondrial succinate dehydrogenase, a notoriously unstable enzyme, and, further, that on ageing succinate dehydrogenase from yeast or animal tissues fumarate reductase activity declines much more slowly than succinate dehydrogenase activity. On the basis of these investigations it was concluded that "while the existence of a separate 'fumaric reductase' is not disproved, the 'reductase' activities of . . . yeast mitochondria may be readily accounted for by the reversible action of succinic dehydrogenase . . ." and it was suggested "that at present no unequivocal evidence points to the existence of a separate 'fumaric reductase' "[11]. The presumed reversible resolution into apoenzyme and FAD by dialysis[4] remained puzzling, however, since the flavin of yeast succinate dehydrogenase is covalently linked to the protein; but the possibility could not be excluded that added FAD acted as a non-enzymatic catalyst, rather than as a prosthetic group, in the experiments of Fischer *et al.*[4].

The problem was later reopened by Kováč[12], who confirmed the findings of Massey and Singer[10,11] but also noted that fumarate reduction in extracts and broken cell preparations of yeast is only partly inhibited by malonate, succinate, and *p*-chloromercuribenzoate, while succinate oxidation is completely inhibited by malonate and mercurials. Kováč concluded that this observation was suggestive but not unequivocal evidence for the existence of two fumarate-reducing enzymes in yeast, fumarate reductase and succinate dehydrogenase, and emphasized that other interpretations were equally conceivable. Differential response to inhibitors is, indeed, tenuous evidence for the existence of a separate fumarate reductase, since it has been shown that fumarate reduction by homogeneous preparations of succinate dehydrogenase from *Micrococcus lactilyticus* is far less sensitive to inhibition by malonate and *p*-chloromercuribenzoate than succinate oxidation[13,14]. Furthermore, treatment of respiratory chain preparations from aerobic yeast with *N*-ethylmaleimide, an –SH inhibitor, the action of which is irreversible, results in extensive loss of succinate dehydrogenase activity without detectable effect on the reduction of fumarate (Table 1).

Another indication of the possible existence of a unidirectional fumarate reductase came from the observations of Peck *et al.*[15] that extracts of the obligate anaerobe *M. lactilyticus* reduce fumarate very rapidly but oxidize succinate only extremely slowly, even in the presence of phenazine methosulphate and that, while succinate oxidation is readily inhibited by malonate and fumarate, the reduction of fumarate is virtually insensitive to inhibition by succinate and by low concentrations of malonate. Further, on preliminary fractionation of the *M. lactilyticus* extract succinate dehydrogenase appeared to be completely absent in certain fractions rich in fumarate reductase[17]. This last observation was traced by Warringa *et al.*[13] to the presence of a substance in crude preparations, which differentially inhibits the reduction of the enzyme by succinate but does not interfere with its reoxidation by fumarate. The other unusual properties of the *M. lactilyticus* enzyme were explained only after succinate dehydrogenase was isolated in pure form from this micro-organism[13]. It was found that a single enzyme is responsible for both the oxidation of succinate and the reduction of fumarate in this micro-organism and that its properties are remarkably different from those of succinate dehydrogenases from aerobic mitochondria. In contrast to mammalian succinate dehydrogenase, it catalyses fumarate reduction far faster than succinate oxidation and possesses a very low Michaelis constant for fumarate, while the K_m for succinate and K_I for malonate are rather large. Hence fumarate is a good inhibitor of succinate oxidation but not vice versa, and malonate competes much more effectively with succinate than with fumarate[13,14].

Table 1. Effect of *N*-Ethylmaleimide on Succinate Oxidation and Fumarate Reduction by Mitochondrial Succinate Dehydrogenase from Yeast

Sample	Succinate dehydrogenase activity		Fumarate reductase activity	
	μmoles succ. oxidized/min/ml. enzyme	Per cent inhibition	μmoles fum. reduced/min/ml. enzyme	Per cent inhibition
ETP	32·4		1·1	
ETP + NEM	6·4	80	1·3	0

The respiratory chain preparation denoted as ETP was prepared from Red Star brand baker's yeast by the method of Mahler *et al.* (ref. 15). Treatment with *N*-ethylmaleimide (NEM) was by incubation of the preparation with 0·5 volume of 10 mM NEM at *p*H 7·0 at 0° for 10 min, followed by removal of the unreacted NEM on 'Sephadex G–25'. Succinate dehydrogenase activity was measured by the phenazine–DCIP assay at V_{max} with respect to phenazine methosulphate at 30° with pre-activation, fumarate reductase activity by the $FMNH_2$ assay at 30° in the presence of 1·33 mM $FMNH_2$.

As has been emphasized in reviews on the comparative biochemistry of succinate dehydrogenases[18,19], these differences are encountered in diverse forms of life and may represent an adaptation to aerobic or anaerobic existence. Those organisms which live in an abundance of oxygen possess succinate dehydrogenases which catalyse the oxidative reaction much faster than the reductive one, and the dehydrogenase from such sources generally shows a high affinity for succinate and a low one for fumarate, while the reverse is true of organisms of a predominantly anaerobic habitat. Succinate dehydrogenase from facultative anaerobes, such as *Propionibacterium pentosaceum*[18] or *Proteus vulgaris*[20], usually shows properties in between those of the mitochondrial enzyme and of the dehydrogenase from strict anaerobes.

Very recently, Hirsch *et al.*[21] demonstrated that *E. coli* cells contain two succinate dehydrogenases, both of them reversible in their action, one of which resembles the mammalian enzyme in the properties mentioned and is found in aerobically grown cells, while the other shows properties typical of succinate dehydrogenases from anaerobes. Although neither enzyme has been purified, their simultaneous presence in the same cell has been established by the use of suitable mutants. This demonstration prompted the present authors to re-examine the possible presence of fumarate reductases in yeast. It will be shown in this paper that yeast cells contain, besides the well-known mitochondrial enzyme, at least two and possibly three additional enzymes concerned with the reduction of fumarate.

Mitochondrial succinate dehydrogenase in yeast. Since information on the properties of succinate dehydrogenase from yeast mitochondria was derived largely from studies on purified, soluble preparations, Rocca *et al.*[22] have recently investigated the properties of the enzyme in

more nearly intact particulate preparations (mitochondria and the sub-mitochondrial particle referred to as "*ETP*" in the literature[15]). The preparations were isolated either by blending with Ballotini beads or with the Nossal shaker, as described earlier[23]. Succinate dehydrogenase was assayed by an adaptation of the phenazine–DCIP method[24], with a fast-recording spectrophotometer, and succinoxidase polarographically. In all respects examined, the molecular and catalytic properties of the enzyme were found to be very close to those of bovine heart succinate dehydrogenase[6]. The turnover number of the dehydrogenase at 30° was 12,500 ± 1,000 moles succinate oxidized/min/mole of bound flavin, a value which is not very different from that reported for the heart enzyme[19] (17,000 ± 1,000 at 38°), considering the difference in temperature. The forward/reverse ratio (succinate + phenazine methosulphate/fumarate + $FMNH_2$) is about 34 ± 2 at 30°, again close to the value found in mammalian mitochondria. With the availability of improved assay techniques even the two differences which were earlier thought to exist between yeast and heart muscle succinate dehydrogenases (activation by the substrate and cyanide sensitivity) have now been shown not to exist[22]. The dehydrogenase is completely absent in 'petite' mutants and virtually absent in anaerobically grown normal cells[22,25]. Thus succinate dehydrogenase in yeast develops only under strongly aerobic conditions and is very similar to its counterpart in mammalian mitochondria.

Fumarate reductases in cytoplasmic preparations. Since yeast mitochondria have been shown to contain unambiguously only one enzyme for the reduction of fumarate to succinate, the respiratory chain-linked succinate dehydrogenase[9,10], it remained to examine whether the extra-mitochondrial phase contained additional proteins capable of catalysing this reaction. When yeast cells are broken by the method recently described by Mahler *et al.*[15] and the supernatant solution obtained in sedimenting the mitochondria is clarified by further centrifugation (20–40 min at 105,000*g* or 1 h at 59,000*g*), followed by titration with protamine sulphate until all detectable succinoxidase activity is sedimented, the resulting optically clear solution still oxidizes succinate in the presence of phenazine methosulphate and reduces fumarate with $FMNH_2$ as donor, but the ratio of the forward/reverse reactions is very much lower than in mitochondria. On passage of this preparation through a column of 'Sephadex *G*-200' the excluded part contains all the remaining succinate dehydrogenase activity: the enzyme responsible will be referred to as enzyme I. The included fraction does not appear to oxidize succinate but reduces fumarate vigorously. From this included fraction two fumarate-reducing enzymes have been separated by chromatography on hydroxylapatite (Fig. 1), which will be referred to as enzyme II and enzyme III.

For the isolation of these enzymes 2 kg of well-washed baker's yeast ('Red Star') were suspended in a final volume of 2 l. with 1 M sucrose–0·02 M *tris*–0·001 M ethylenediamine tetraacetate (EDTA), *p*H 8·0, and were blended with 2 l. of Ballotini beads at 0° with an overhead blender and circular glass blade, as described by Mahler *et al.*[15]. Blending was continued for 28 min, with interruptions each 7 min for cooling the suspension. The suspension was poured off and brought to 3 l. by washing with 250-ml. aliquots of a 4-fold dilution of the sucrose–*tris*–EDTA solution referred to above. Sufficient 1 M dipotassium hydrogen phosphate was added to adjust the suspension to 0·05 M phosphate concentration and the *p*H was brought to 7·5 with 1 N potassium hydroxide. After 30 min centrifugation at 2,000*g*, the turbid supernatant solution was further centrifuged for 1 h at 59,000*g* in the Spinco ultracentrifuge, and the residue was discarded. The supernatant solution was precipitated with 0·7 saturated ammonium sulphate at *p*H 7·0–7·5; the precipitate was redissolved in dilute phosphate buffer and titrated with protamine sulphate (1 per cent in 10 mM phosphate, *p*H 7·6) until all turbidity and succinoxidase became readily sedimentable. The clarified solution was then precipitated with solid ammonium sulphate at *p*H 7·0–7·5 and the fraction precipitating between 0·2 and 0·7 saturation was collected. Ammonium sulphate was removed on 'Sephadex *G*-25' and the preparation was passed through a column of 'Sephadex *G*-200', equilibrated with 0·03 M phosphate, *p*H 7·5. The excluded fraction, containing enzyme I, and the included part, containing enzymes II and III, were separately concentrated by precipitation with solid ammonium sulphate at 0·7 saturation and neutral *p*H. Enzymes II and III were separated from each other on hydroxylapatite, as shown in Fig. 1. Rechromatography of either of these enzymes on hydroxylapatite gave single, symmetrical peaks and no indication of contamination with the other enzyme. Considerable additional purification of enzymes II and III was achieved by fractionation with ammonium sulphate.

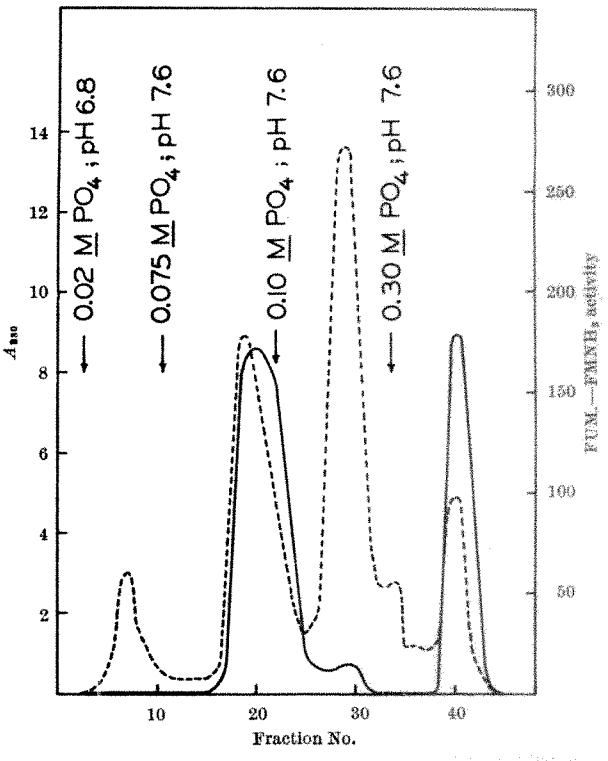

Fig. 1. Separation of the two low molecular weight fumarate reductases on hydroxylapatite. Solid line denotes activity in the fumarate–$FMNH_2$ assay, interrupted line absorbancy at 280 mμ. When rechromatographed on another hydroxylapatite column, both enzyme II (0·075 M phosphate eluate) and enzyme III (0·3 M phosphate eluate) gave single, symmetrical peaks

Known properties of enzyme I closely approximate those of succinate dehydrogenase from yeast mitochondria in soluble, purified preparations[9]. It is completely excluded on 'Sephadex *G*-200'; hence the molecular weight is of the order of 200,000 or higher. (The molecular weight of the mitochondrial enzyme is about 200,000.) Enzyme I is activated by the substrate and by competitive inhibitors; it is highly sensitive to malonate; it is present in aerobic but not in anaerobic cells; it oxidizes succinate with phenazine methosulphate as electron acceptor but does not react appreciably with cytochrome *c*, ferricyanide, or DCIP. The ratio of the forward/reverse reactions (succinate + phenazine methosulphate/fumarate + $FMNH_2$) is 7·6 at 30°, while the dehydrogenase solubilized from mitochondria shows a ratio of 9 in strictly fresh preparations, and this ratio declines gradually on storage[9,10].

Since enzyme I is present in very small amounts in the cytoplasmic preparation, at present it is uncertain whether it is derived from the mitochondria during the mechanical

Table 2. Comparison of Kinetic Constants of Fumarate-reducing Enzymes from Yeast

Constant	ETP from mitochondria	Cytoplasmic, Type II	Cytoplasmic, Type III
K_m fumarate	1·82 mM	1·43 mM	0·89 mM
K_I succinate	3·44 mM	6·1 mM	4·2 mM
K_I malonate	0·11 mM	0·79 mM	0·49 mM

Constants were determined by the manometric hydrogenase–$FMNH_2$ assay at 30°.

breakage of the cells and thus represents a small degree of solubilization of the mitochondrial enzyme, or whether it is a genuine cytoplasmic constituent, conceivably a precursor or breakdown product of the respiratory chain-linked enzyme.

In contrast, enzymes II and III bear very little resemblance to mitochondrial succinate dehydrogenase either in the soluble or the particle-bound form.

(1) They are completely included in 'Sephadex *G*-100' and '*G*-200' and partly included in '*G*-75'; hence their molecular weights may be about 50,000. (2) In contrast to the mitochondrial enzyme, they are present at undiminished levels in anaerobically grown normal yeast and in 'petite' mutants. (3) They are far more stable than the mitochondrial enzyme to a variety of treatments. (4) They do not appear to contain covalently bound flavin. (5) They do not oxidize succinate with phenazine methosulphate, ferricyanide, DCIP or cytochrome *c* as electron acceptors. Attempts to establish a bleaching of these flavoproteins by succinate under anaerobic conditions have thus far given negative results. Since succinate is a competitive inhibitor of both enzymes II and III (Table 2), clearly succinate combines with their active centres. Conceivably, the failure to detect a net oxidation of succinate may be the consequence of an unusually low redox potential of the flavin in these proteins. Lastly, they differ both from the mitochondrial enzyme and from each other in regard to kinetic constants (Table 2). Enzymes II and III have lower K_m values for fumarate and higher K_I values for succinate and malonate than the respiratory chain-linked enzyme, and thus also in this regard they resemble the fumarate-reducing enzymes of strict anaerobes[14].

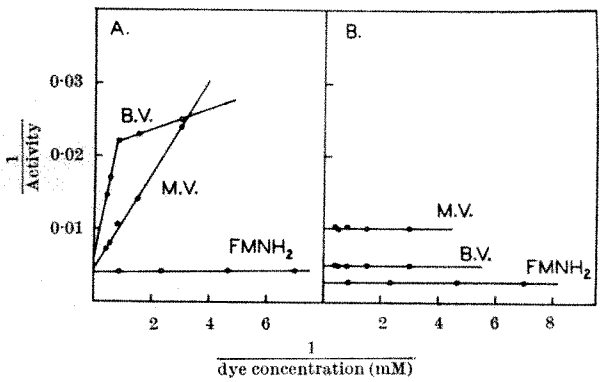

Fig. 2. Comparison of specificities of enzyme II (*A*) and enzyme III (*B*) for electron donors. *M.V.*, methylviologen; *B.V.*, benzylviologen. All assays were at 30°, *p*H 7·6 by manometric measurement of hydrogen uptake in the presence of excess hydrogenase from *Cl. pasteurianum* (ref. 26). The biphasic curve seen with benzylviologen in *A* is often noted with this dye and is due to impurities present even in recrystallized preparations of the dye (ref. 13)

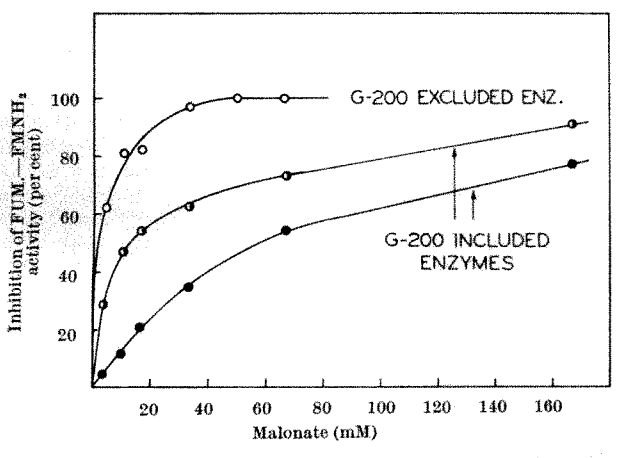

Fig. 3. Malonate sensitivity of fumarate-reducing enzymes from yeast cytoplasm. Activities noted on the abscissa refer to the fumarate–$FMNH_2$ assay at 30°, *p*H 7·6 in the presence of 2 mM fumarate. Open circles, enzyme I; solid circles, enzyme II; half-shaded circles, enzyme III

Known differences between enzymes II and III, besides those already mentioned, are as follows. They show somewhat different *p*H optima in the fumarate–$FMNH_2$ assay[26]; they precipitate at different concentrations of ammonium sulphate; enzyme II is more stable to storage and to exposure to acid *p*H than enzyme III; they show different reaction patterns with electron donors (Fig. 2) and different sensitivities to inhibition by malonate (Fig. 3). Further, while enzyme II is neither inactivated nor split into apoenzyme and flavin at *p*H 3·5 in the presence of ammonium sulphate, enzyme III is reversibly resolved into apoenzyme and flavin by this treatment.

It should be emphasized that, while the findings recorded here establish the presence of several fumarate-reducing enzymes in yeast, two of which appear to be incapable of oxidizing succinate, at least under the conditions tested, none of the enzymes discussed can be readily identified with Fischer's "fumaric hydrogenase" since they are neither inactivated to an appreciable extent nor resolved into apoenzyme and FAD by dialysis under the conditions used by Fischer *et al.*[4].

The biological function of these new enzymes is of considerable interest. Conceivably they are concerned with the production of succinate under conditions where the Krebs cycle is not functioning and thereby provide an important intermediate for synthetic reactions.

LETTERS TO THE EDITOR

ASTRONOMY

A Case for Convection in the Moon

MODERN workers are agreed that the Moon has a small bulge, measured with reference to the mean radius of the limb, pointing in the direction of the Earth. The order of magnitude of this body-elongation is 0·1 per cent of the radius, but the actual value assigned to it depends quite critically on the selection of measured points used in the analysis.

A recent re-determination of the height of the bulge has been made by Baldwin[1], who separated points lying in the dark regions (excluding the deep, circular maria) from those of the bright regions (excluding the high mountains) and found values of about 1·2 km and 2·0 km, respectively. Conceding that the bulge is not significantly different in the low continents and in the irregular maria it seems that an explanation involving widespread uniformity of stress must be sought. For this reason I shall not detail the suggestion of Jeffreys[2], that the bulge was due to "irregular changes arising after solidification", or of Urey[3], that it was built up as a net deposit from differential impacts. Baldwin[1] has attributed the bulge to early tidal forces, while Runcorn[4] has proposed that currently operating convection cells keep the Moon's surface buoyed up as they rise in the centre of face.

The Moon's mechanical ellipticity, f, is found from observations to be at least 0·6 (cf. ref. 5). If the Moon had solidified as a synchronous satellite of the Earth the much smaller value $f = 0{\cdot}25$ would obtain[6]; hence it is difficult to believe that the bulge can be a fossil tide raised by the Earth. Baldwin[1] has postulated that the bulge was indeed raised when the Moon was a synchronous satellite bound close to the Earth, but that "the theoretical value of $f = 0{\cdot}25$ is more or less completely masked by the larger surface variations".

Yet on Baldwin's theory the original bulge formed more than 4×10^9 yr ago and, as the bulge is still present in the maria, their surfaces, too, must be very old. This seems to me to be a serious objection to the theory, for I find it difficult to believe that so few impact craters have formed in the maria in 4×10^9 yr. With different (I consider more realistic) assumptions about the rate of crater growth, based on crater-counts, I have found[7] that even the oldest maria are but one-seventh as old as the continents. It therefore seems to be at least equally reasonable to suppose that no mare is older than 7×10^8 yr. On this hypothesis the Moon would be little nearer to the Earth, when the maria were formed, than it is to-day; and the observed bulge in the maria could not have been raised by the appropriately weak value of the Earth's attraction.

Runcorn's convection theory[4] provides a solution to this problem: the general form of the bulge would be similar in the continents and in the maria if they were uplifted uniformly by rising convection currents. Regional isostatic adjustments could occur, as in the case of Baldwin's theory. There are, moreover, additional reasons for advocating a convection theory.

First, convection currents provide a means of carrying heat to the surface, and they would assist the mare melting and the Moon's differentiation that many authors advocate. Secondly, it is important to find an explanation for the remarkably uniform system of strike-slip faults[8] that traverse the Moon's face. A triaxial Moon adjusting to the equipotential shape is inadequate to explain this lunar grid system. Tidal forces are also unlikely to have been responsible unless, possibly, the Moon was warm at the time[9]. However, specially oriented, low-order convection cells would exert a drag on the crustal layers of the Moon, and the drag at any point would be fixed in direction for a very long period of time and, specifically, during the recent era of lunar history. In principle, this mechanism is capable of providing an explanation of the grid system.

Urey[10] has suggested that the lunar continents are between $3{\cdot}0 \times 10^9$ and $4{\cdot}5 \times 10^9$ yr old. I have estimated[7] that Mare Imbrium is only 1/19th of the age of the continents, so Mare Imbrium may have an age of 2×10^8 yr. Mare Frigoris appears to be of the same order of age[7]. The 'Frigorim Fault'[11] links Mare Imbrium and Mare Frigoris. It appears to be the longest strike-slip fault on the Moon, and has an offset of 200 km. It cannot be traced in the maria themselves, so it must be at least as old as they are; hence the maximum rate of movement along this major fault has been $\sim 0{\cdot}1$ cm yr^{-1}. This figure is not in conflict with Runcorn's estimate[12] of $\sim 0{\cdot}2$ cm yr^{-1} for the rate of creep of the lunar convection currents.

I thank Imperial Chemical Industries, Ltd., for a research fellowship.

RADIO ASTRONOMY

Spectra of the Galactic Radio Emissions

RECENT observations of the spectra of the galactic emissions in the 1–10-Mc/s frequency range using satellite, rocket and ground-based receivers have produced apparently conflicting results[1–4].

The disagreement may be due partly to the difficulty of calculating the antenna efficiency in the ionospheric plasma for the orbital receivers, although the spectra obtained in the different ways have not been directly comparable since the low-resolution antennæ used above the ionosphere have looked at different areas of the sky from those surveyed from the ground. High-resolution studies[5], for example, have shown pronounced absorption within the galaxy, depending on galactic latitude and with an angular scale smaller than the beamwidth of the antennæ used for spectral observations. Below 3 Mc/s the absorption can be seen in the high-resolution profiles right out to the galactic pole[6].

It is suggested here that low-resolution spectra are meaningful only for directions near the poles where the brightness distribution is fairly uniform. The previously published ground observations did not meet this requirement since they were given for directions where the observed intensities were greatest and least during the right ascension scan. These directions were declination $-42°$, R.A. 2000 and R.A. 0400 h respectively. That is, galactic latitudes 30° and 45°, longitudes 325° and 214°. The subsequent high-resolution surveys showed consider-

able absorption in these directions compared with the polar direction.

Fig. 1 shows the intensities observed at Hobart at 1·65 Mc/s, 2·4 Mc/s, 4·8 Mc/s and 9·6 Mc/s for Dec. −42° and R.A. 0030 (galactic latitude −80°); that is, in the vicinity of the south galactic pole. The experimental details have been described previously. The antenna beamwidths were 32° × 40°. The attenuation in the ionosphere was calculated using observed *D*, *E* (ref. 7) and *F* (ref. 8) region density profiles and, at 1·65 Mc/s, amounted to 0·25 db for the ordinary mode and 480 db for the extraordinary mode. The effect of the ground on the antennæ was calculated after measuring the ground conductivity. The screening of the edges of the antenna beam by the ionosphere was calculated using observed values of f_0F_2. The attenuation allowed for by screening was 0·5 db at 1·65 Mc/s. Also shown in Fig. 1 are results obtained by Walshe *et al.*[3] and Hartz[4], although as mentioned earlier these are not strictly comparable.

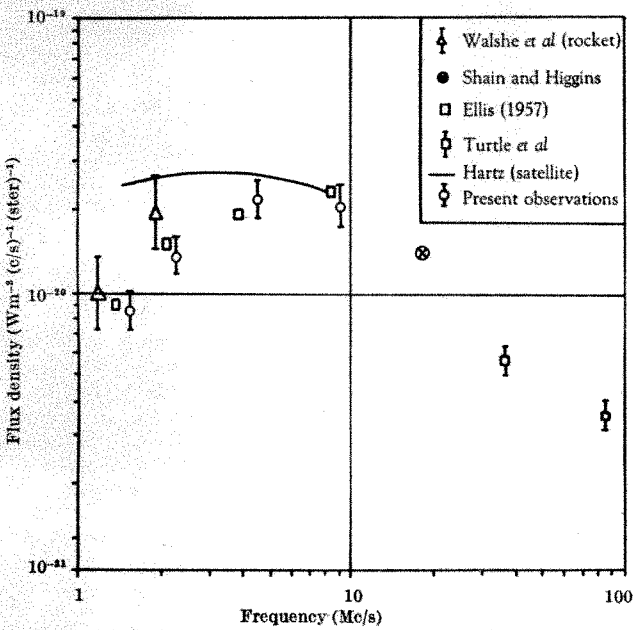

Fig. 1. Comparison of low-resolution cosmic radio noise intensities in the direction of south galactic pole (observed at Hobart) with satellite and rocket observations. Representative higher frequency points are also shown (refs. 10–12)

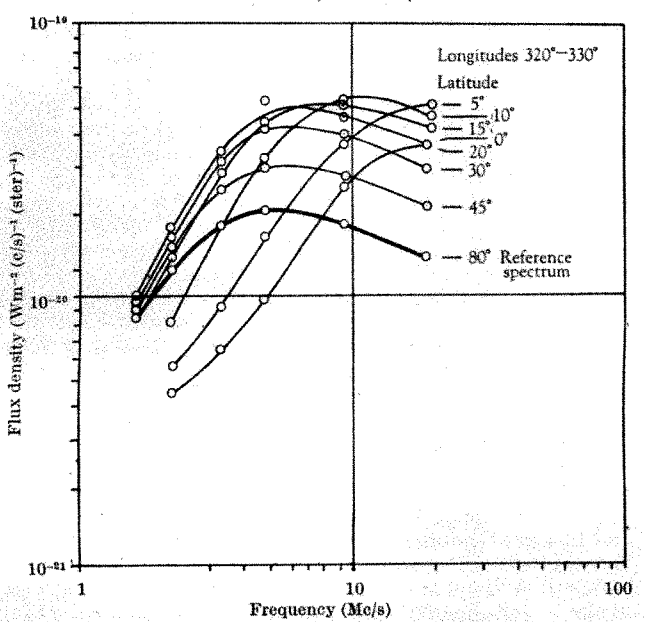

Fig. 2. High-resolution spectra at low galactic latitudes derived from Fig. 1 and brightness profiles of Ellis *et al.*[5]

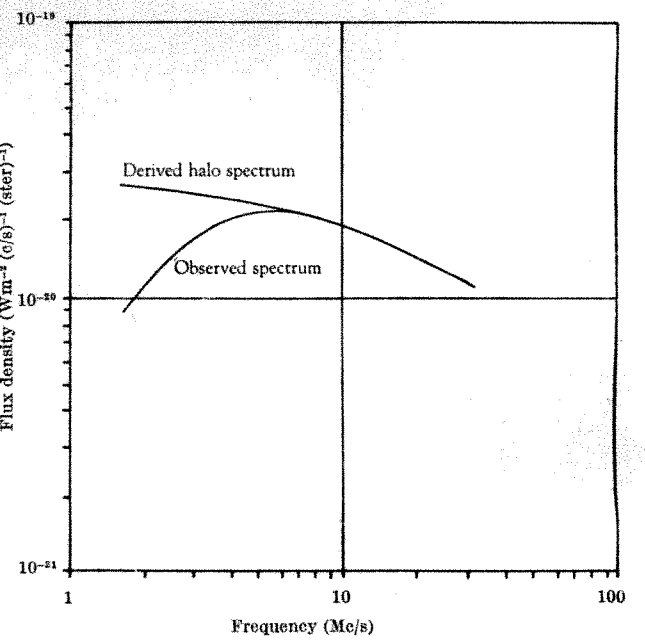

Fig. 3. Derived emission spectrum in the halo region

By using the spectrum in the direction of the pole as a reference we may construct the spectra in other directions using the high-resolution brightness profiles of Ellis and Hamilton[6]. These spectra are shown in Fig. 2. It is noteworthy that for low galactic latitude where the absorption is high the intensities at low frequencies have a spectral index of +2, that is, intensity $S \propto f^2$, as would be expected for a strongly absorbing interstellar medium[9].

Finally, it has been shown that the absorption coefficient in the galactic disk may be obtained from the change in shape of the high-resolution profiles only, and independently of absolute measurements of intensity. Ellis and Hamilton[6] found the absorption coefficient K to be $2{\cdot}5 \times 10^{12}$ cm^{-5} (°K)$^{-3}$ in the direction of the south galactic pole and the emission measure 1·92 cm^{-6} pc. The observed flux density S is proportional to $e^{-\int K dl}$ where $K = \dfrac{0{\cdot}4N^2}{T^{3/2}f^2}$.

We are able therefore to calculate the absorption in the disk at any frequency and hence, with the observed high-latitude spectrum as a starting point, calculate the emission spectrum for the radiating electrons outside the disk. This spectrum is shown in Fig. 3. It shows a flattening towards the low-frequency end with a spectral index of −0·15. This might be expected from ionization losses or some other process leading to depopulation of the lower-energy electrons[9].

PHYSICS

Amorphous Magnetic Films

IRON has been vapour-deposited on to amorphous carbon substrates at room temperature and examined, while it was being deposited, by direct-recording electron diffraction[1]. Fig. 1 shows electron-intensity profiles along a radius vector of the Debye–Scherrer pattern. Successive traces recur every 50 sec at film thickness increments of about 20 Å. In Fig. 1*a* the profiles correspond to an amorphous structure; however, as the film grows sharp peaks appear, beginning in the final trace. These sharp peaks grow rapidly, initially at the expense of the diffuse ones; compare the first and fourth traces in Fig. 1*b*. The sharp peaks are those of normal b.c.c. iron, with measured lattice spacing 2·87 Å. If the deposition is continued beyond the stage represented by trace 4, Fig. 1*b*, there is little further change in the shape of the diffraction profiles but their intensities diminish as the film becomes more opaque.

Specimen growth may be stopped at any stage desired and the film transferred from the diffraction equipment to an electron microscope and there examined by diffraction, normal high-magnification and by Lorenz microscopy[2]. Fig. 2 shows a Lorenz micrograph of a film in the amorphous state. This was confirmed by diffraction photographs taken before and after the Lorenz microscopy. Fig. 2 shows a magnetic domain structure : from this and a knowledge of film thickness an estimate of the magnetization $M \simeq 0{\cdot}35$ Wb/m² may be made. Thicker films which have largely crystallized have a value of M of 1·4 Wb/m², which may be compared with the value 2·15 Wb/m² for bulk iron.

The amorphous-crystalline transformation appears reproducible: a total of 42 specimens have been grown on carbon and all show the phenomenon. The transformation also occurs when the substrate is a layer of SiO previously deposited on the carbon.

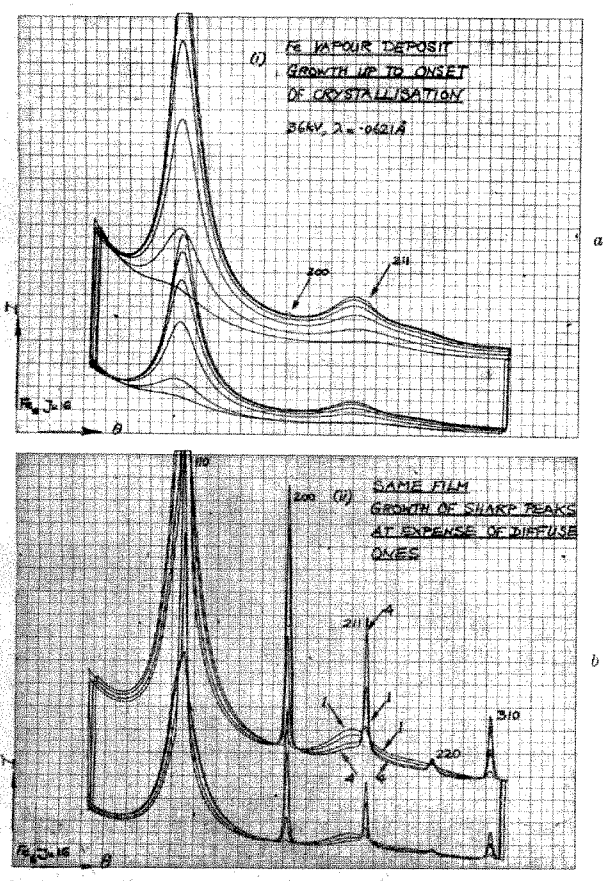

Fig. 1

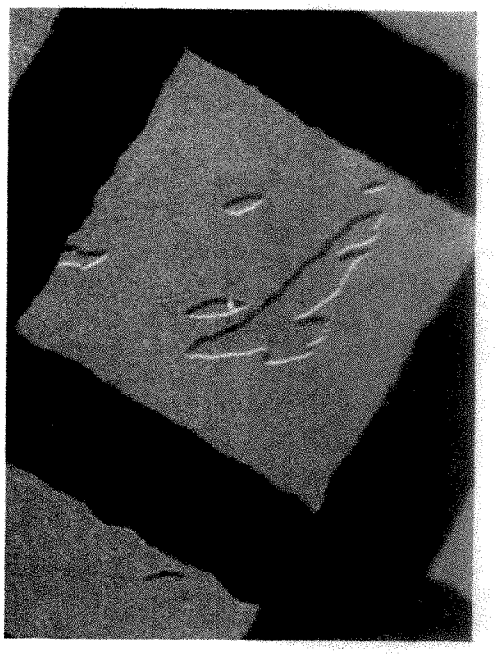

Fig. 2

Since the growths are made in a vacuum of 2×10^{-6} torr when the substrates will be covered with adsorbed gas molecules, there is some doubt whether the amorphous material is iron or some other compound. However, once recrystallization begins some of the amorphous matter itself transforms to crystalline iron. Moreover, if an amorphous film is heated, by increasing the illumination intensity in the electron microscope, it transforms to crystalline iron. These two facts suggest that the amorphous material consists chiefly of iron atoms.

We conclude that an amorphous magnetic state of matter has been found, for which the band theory model of Stoner[3] cannot apply; and that the amorphous material is probably iron.

Quantity Equations and System Variation in Electricity

IN electricity there exists an unsettled dispute concerning the nature of system variation, that is, the transition from one system to another. According to one of the parties in the dispute, system variation is caused by a variation of units, whereas the other party maintains that system variation is caused by a variation of quantities[1,2]. In a recent article[3] I demonstrated that this variation consists in a change in the form of quantity equations without a change in quantities. As a consequence some units become incoherent and may be replaced by other units, which are now coherent with the changed equations. In the following a résumé of the problem in question is given.

The electromagnetic equations in the Giorgi system differ from the equations in the three classical systems (electrostatic, electromagnetic, symmetric) mainly in two points: (1) the 'sphere factor' 4π appears in the Giorgi system in equations other than in the classical systems ('rationalization'); (2) the 'permittivity of free space', ε_0, and the 'permeability of free space', μ_0, are introduced in the equations of the Giorgi system; these coefficients are unknown in the classical systems.

A typical example illustrating point (1) is the equation connecting magnetic field strength and current. This equation reads $\oint H\mathrm{d}s = I$ in the Giorgi system and $\oint H\mathrm{d}s = 4\pi I$ in the electromagnetic system. A typical example for point (2) is Coulomb's law, which reads $F = Q_1Q_2/(4\pi\varepsilon_0 r^2)$ in the Giorgi system and $F = Q_1Q_2/r^2$ in the electrostatic system.

There are two divergent explanations for these dissimilarities:

(I) The electromagnetic equations are 'measure equations'. In the different systems different units are used. For example, the Giorgi unit for H is 4π times that of the electromagnetic system, apart from the decimal conversion factors for the units of I and s; the electrostatic unit of Q is defined by the mechanical units of force and length; the Giorgi unit of Q may be considered as an independent electrical unit, hence the coefficient ε_0.

(II) The electromagnetic equations are relations between 'quantities', a quantity being symbolized by the product of a measure and a unit. In the various systems a certain number of physical laws are described by means of quantities which are defined in different ways. In our examples the relation between the rationalized H_r from the Giorgi system and the non-rationalized H_n from the electromagnetic system is:

$$H_n = 4\pi H_r$$

The quantity Q_G from the Giorgi system with four fundamental quantities and the quantity Q_e from the electrostatic system with three fundamental quantities are connected by:

$$Q_e\sqrt{4\pi\varepsilon_0} = Q_G$$

With regard to explanation (I), it is not very elegant to consider the symbols in the electromagnetic equations as measures. These equations formulate laws, that is, relations between physical quantities. These laws and quantities are independent of units. Measure equations apparently do not do full justice to this fact.

In explanation (II), to consider the symbols in the electromagnetic equations as quantities does emphasize the said independence. To consider system variation as a variation of quantities, however, is even less elegant than explanation (I), because in this case physical quantities seem to depend on the choice of the system. For example, there exists from the point of view of (I) only one quantity 'charge', whereas from the point of view of (II) one has to distinguish between the quantities Q_e and Q_G, thus violating the original intention of accentuating the independence of physical quantities from units and systems.

I have recently demonstrated[3] that the essential difference between the electromagnetic systems does not consist in a change of units or quantities, but in a change in the form of the equations and hence in a change in the coherence of units. The gist of the matter may be seen with the aid of our example regarding H. The underlying law is: $\oint H\mathrm{d}s \sim I$. This stands for:

$$\frac{\oint H\mathrm{d}s}{\oint H_1\mathrm{d}s} = \frac{I}{I_1}$$

where H, I and s are a combination with arbitrary values of I and s, and H_1, I_1 and s_1 are a combination with known values of field-strength, current and length. The right-hand side of this quantity equation may also be written: $kI/(kI_1)$. In the Giorgi system $k = 1$ has been chosen, in the electromagnetic system $k = 4\pi$. As a consequence, the 'coherent Giorgi unit' for H would be 4π times the 'coherent electromagnetic unit' for H, if one should use the same units for I and s in both equation systems. In fact, because 1 cm = 0·01 m and 1 amp = 0·1 e.m.u. of current, one has 1 amp/m = 1œ × 4π/1000.

GEOLOGY

Implication of Certain Sedimentary Structures within the Cambrian Succession of the St. Tudwal's Peninsula, South-west Caernarvonshire

The source and depositional environment of the Cambrian sediments in the Lleyn Peninsula, North Wales, has been the subject of much dispute. Early work by Nicholas[1] described some of the sedimentary structures, but their importance in relation to the palæogeography of the Welsh geosyncline was first discussed by Kopstein[2] working in the Harlech Dome and later by Bassett and Walton[3] in the St. Tudwal's Peninsula. Each member of the succession can be correlated with similar horizons in the Harlech Dome[4].

Recent work (unpublished) in the Harlech Dome has shown the structural pattern to be more complex than has previously been supposed; consequently certain of the methods used by Kopstein are now known to be inapplicable. He concluded that, with the exception of the Dolwen Grits, palæocurrent evidence indicated derivation of the sediments from the south-south-west during the whole of the Cambrian. Bassett and Walton, however, concluded that the source of the Lower Cambrian Hell's Mouth Grits lay to the north. Knill[5] suggested that the Lower Cambrian Rhinog Grits of the Harlech Dome were derived from the north-east while the overlying Barmouth Grits appeared to have been largely derived from the south-west.

A limited number of readings taken from sedimentary structures within the Lower Cambrian Hell's Mouth Grits and Mulfran Beds are in agreement with those of Bassett and Walton, indicating a northerly source. The overlying Cilan Grits yield variable current directions, but within the Ceiriad Mudstones and Nant-Pig Mudstones there is evidence of a south-westerly source. There are, however, relatively few palæocurrent structures within this mid-Cambrian part of the succession.

Table 1. Relevant Part of the Succession of the Cambrian of St. Tudwal's Peninsula and the Harlech Dome

St. Tudwal's Peninsula	Harlech Dome
Lingula Flags	Vigra Flags
Nant-Pig Mudstones	Clogau Shales
Ceiriad Mudstones	Gamlan Shales
Cilan Grits	Barmouth Grits
Mulfran Beds	Manganese Shales
Hell's Mouth Grits	Rhinog Grits
	Llanbedr Slates
	Dolwen Grits

The Upper Cambrian Lingula Flags have a large number of exceedingly well-preserved structures which show that, during the deposition of the lower beds, currents from the south-westerly quadrant were active; a few hundred feet above the base, however, the current direction was from the south-south-west. On the east side of Porth Ceiriad there is a small exposure which probably represents a higher horizon in the Lingula Flags and here the current direction was from the south-south-east.

Thus, in general, currents appear to have travelled from the north in the Lower Cambrian and from the south in

the Upper Cambrian. The pattern of currents in the Cambrian is more complex and variable than has previously been suggested, consequently caution should be exercised in interpreting the palæogeographic importance of these and similar results, until more extensive regional investigations are completed.

Iron-deficient Low-temperature Pyrrhotite

During the past few years considerable attention has been focused on the potential of pyrrhotite as a geothermometer. In 1962 Arnold[1] determined experimentally the solvus relationship between hexagonal pyrrhotite and pyrite, thereby demonstrating that the percentage of iron in pyrrhotite along this solvus was temperature dependent, but insensitive to pressure. The potential of this method was then tested on samples from the Highland-Surprise Mine[2] and the temperatures obtained from the pyrrhotite geothermometer were found to agree well with those obtained from associated sphalerite using the sphalerite geothermometer[3]. More recently, Buseck[4] and Kullerud *et al.*[5] have attempted to apply the method to monoclinic pyrrhotite–pyrite assemblages by inverting the monoclinic pyrrhotite to hexagonal symmetry by heating.

The occurrence of pyrrhotite in the northern Pennine orefield[6], although limited, is of interest because fluid inclusion studies have shown that depositional temperatures of fluorite and quartz, the two most abundant minerals in the central portions of the field, are below 250° C. To our knowledge the only reported instance of pyrrhotite formed under hydrothermal conditions at temperatures below 250° C is that described by Balitskii and Lyubofeyev[7]. Accordingly, these pyrrhotites were investigated in detail to ascertain whether they were in fact deposited at temperatures below 250° C and whether the pyrrhotite geothermometer could be applied to them.

The results obtained from pyrrhotite and associated minerals from localities in the Rookhope Borehole[8] and the Great Sulphur Vein[9] are summarized in Table 1.

At 1,083 ft. the borehole intersected a small replacement body of quartz and fluorite in the Smiddy Limestone. Here, the time relationships of the various minerals are obscure, but pyrrhotite-sphalerite and pyrrhotite–pyrite intergrowths occur on a very small scale. The veins intersected at depths of 1,355 ft. and 1,562 ft. in the Rookhope Borehole are in granite and have a maximum thickness of 6 in. The pyrrhotite appears to have formed at a very late stage for it invariably occurs in the centre of veins and in small vugs.

The Great Sulphur Vein is a large east–west vein which consists of quartz accompanied by small amounts of iron sulphides and traces of chalcopyrite. The available geological evidence (K. C. Dunham, personal communication) suggests that it represents the root of what must have been an extensive fluorite–quartz–galena vein at higher levels. This conclusion is supported by the reported occurrence of quartz and pyrrhotite in cores from drill holes in the lowest level of the Cammock Eals Mine of the Slitt Vein (K. C. Dunham, personal communication).

Arnold and Reichen[9] and Arnold[1] demonstrated that the d (102) spacing of hexagonal pyrrhotite is a function of its composition. The d-spacing of the pyrrhotite peak (102) was determined first on natural separated samples, and then on samples heated to 350° C in evacuated glass tubes following the method suggested by Buseck[4]. Silicon was used as an internal standard. The temperatures shown in Table 1 were then estimated using the graphs relating d-spacing to iron/sulphur ratio and then iron/sulphur ratio to temperature[1]. Full traces of the sample from 1,355 ft. in the Rookhope Borehole were run from 14°–90° 2θ to examine the changes resulting from the heating. The natural sample was monoclinic but on heating it inverted to hexagonal symmetry with cell parameters a = 3·45 Å and c = 5·67 Å. In Table 1 values for the twin peak (102) are given, but after heat treatment only a single peak was obtained. An X-ray spectrographic analysis of this material indicates that manganese, cobalt and lead are all present in amounts less than 1 per cent and nickel and copper in amounts less than 0·1 per cent. The appearance of an additional twin peak with d-spacings of 2·088 and 2·092 in the sample from 1,083 ft. suggests the presence of two pyrrhotites, one of which approaches stoichiometric FeS. This conclusion is supported by the occurrence of small amounts of pyrrhotite at 1,895–1,898 ft. with a d-spacing of 2·08 Å measured from a powder photograph.

The iron contents of banded sphalerite from 940 ft. and sphalerite intergrown with pyrrhotite from 1,083 ft. were estimated by calculating cell parameters from the d-spacings of the peaks (331) and (422). 'Analar' sodium chloride was used as an internal standard. These sphalerites proved to have identical cell parameters (a = 5·409 Å), indicative of temperatures less than 250° C. The absence of associated pyrrhotite in the sample from 940 ft., however, suggests that this temperature will be a minimum. Chemical analysis of this banded material by the method of Shapiro and Toulmin[10] gave 0·37 per cent iron for the light bands and 2·31 per cent iron for the darker variety. Both results are in broad agreement with the X-ray data.

The temperatures quoted in Table 1 for fluorite and quartz were obtained from the filling temperature of primary fluid inclusions. An estimated correction for pressure of + 20° C has been added to these filling temperatures to take into account the relationship between the filling temperature of the fluid inclusions and their true

temperature of formation. The precise relationship between filling temperatures and temperatures of formation of fluid inclusions can only be determined when the difference between the vapour pressure of the hydrothermal solutions and the total pressure is known[11]. As a result, whereas the filling temperatures are subject to an uncertainty of only ± 5° C, the temperature of formation of these inclusions is subject to an uncertainty of ± 25° C.

There is a marked discrepancy between the temperature results obtained from the pyrrhotite geothermometer and those obtained from fluid inclusions in minerals closely associated with the pyrrhotite. Further evidence for this discrepancy can be obtained from a consideration of the maximum possible pressures that could have existed during the emplacement of the Great Sulphur Vein. The maximum stratigraphic thickness that ever existed above the level from which the samples were taken was almost certainly less than 5,000 ft.[12,13]. Even if the rising solutions were subjected to the full lithostatic load of these overlying sediments the total pressure on them could not have exceeded 400 bars. At 530° C (cf. Table 1) the vapour pressure of aqueous solutions containing 5–20 wt. per cent sodium chloride (the most probable range of salinity for hydrothermal solutions, cf. Roedder[14]) is between 600 and 680 bars[15]. Thus, the pyrrhotite and associated quartz would have had to be transported by supercritical solutions. The results of calculations by Krauskopf[16] indicate that ore transport by supercritical fluids is unlikely.

The possibility that the pyrrhotite from the Rookhope Borehole represents an early high-temperature phase of ore deposition must be excluded since it invariably occurs in the centre of the veins and in some instances is intergrown with pyrite or sphalerite. In addition, the position of the pyrrhotite within the veins precludes the possibility of a large temperature gradient across the veins. The results of this investigation suggest that iron-deficient pyrrhotites can be deposited at temperatures below 250° C and that the pyrrhotite–pyrite solvus determined by Arnold cannot in all cases be applied to monoclinic pyrrhotites even after the pyrrhotite in question has been inverted to the hexagonal form.

We thank Prof. K. C. Dunham for his advice. This work forms part of the Rookhope Borehole Project financed by the Department of Scientific and Industrial Research, who also provided financial support for two of us (F. J. Sawkins and A. C. Dunham). The X-ray spectrographic data were supplied by Mrs. Maureen Kaye, and the iron determinations made by R. Lambert.

MINERALOGY

Bonding of Hydrogen in Hydrogen-Montmorillonite

Research concerning bonding conditions for tritium and deuterium in micaceous minerals, as formerly mentioned by us[1], indicated the presence of apical OH in dioctahedral hydro micas. Burns and White[2] conclude from infra-red examination after hydrogen saturation and heating of $LiNO_3$-treated muscovite that hydronium ions H_3O^+ replace interlayer cations, giving rise to an infra-red absorption band at considerable bathochromic shift from the normal OH band of the mica (3,472 cm^{-1} respectively 3,600 cm^{-1}). In order to elucidate the bonding problem of the protons of hydrogen micas we have examined the very pure dioctahedral montmorillonite from Skyrvedalen, already described by one of us (I. Th. R.)[3]. As acid treatment tends to attack the silicate lattice we have obtained the desired hydrogen-substituted minerals by introduction of NH_4^+ in the exchangeable positions and subsequent dissociation of NH_3 by heat treatment.

The natural mineral corresponds to the following formula:

$$(Ca_{0\cdot24}Na_{0\cdot61})(Mg_{0\cdot36}Al_{1\cdot62}Fe^{III}_{0\cdot02})(Si_{3\cdot87}Al_{0\cdot13})O_{10}(OH)_2 \cdot 1\cdot08\ H_2O$$

0·49 exchangeable val.

This mineral has been treated for exchange with D_2O, NH_4Ac or ND_4Ac and afterwards heated to various temperatures in various atmospheres. Fig. 1 gives the infra-red absorption between 4,000 and 500 cm^{-1} of some characteristic samples. To facilitate comparison the diagrams have been redrawn to scale so that the Si—O band at 1,020 cm^{-1} is given the same intensity by all samples.

The infra-red absorption of the D_2O (and OD) in calcium montmorillonite is seen by comparing diagrams *A* and *E*. By heating to 420° C it was found that the NH_4^+ or ND_4^+ in interlayer position completely disintegrated: in air by oxidation to H^+, N_2 and water, in nitrogen by dissociation in D^+ and ND_3.

As seen from Fig. 1, *D* and *G* to *K*, H^+ from the hydrogen montmorillonite and D^+ of the deuterium montmorillonite do not give any other bands than those of OH and OD. By heating in moist air the OD band diminishes concordantly to the increase in the OH band. We therefore conclude that the dry hydrogen montmorillonite transforms in such a way that the interlayer H^+ respectively D^+ combines with an O of the montmorillonite lattice, giving rise to normal OH or OD bands. The presence of any H_3O^+ which may exist in interlayer positions in hydrogen montmorillonite in the moist state, is not revealed after heating either by infra-red or by nuclear magnetic resonance. Only very faint indications to the presence of bands that may correspond to the 3,472 cm^{-1} band described by White and Burns can be seen (Fig. 1, *J*, *K*). The bands at 3,520 respectively 2,590 cm^{-1} are, however, far too weak to equivalate the 0·49 protons respectively deuterons introduced by the exchange reaction.

The ammonium treatment and subsequent heating to 420° C reduced the base exchange capacity of the montmorillonite from 110 m.equiv. to 80 m.equiv. per 100 g, whereas the same heating of the calcium montmorillonite without previous ammonium exchange only reduced the exchange capacity at most from 110 to 105 m.equiv.

Introduction of ammonium and subsequent heat treatment reduced the *b*-axis of the mineral by 0·072 Å (a shift in the 060 line from 1·502 to 1·490). Such a contraction of cell dimension may be explained by the introduction of H's in vacant octahedrons, as predicted by us[4]. This will also necessarily reduce the negative charge and the base capacity. It seems to fit with the X-ray finding of

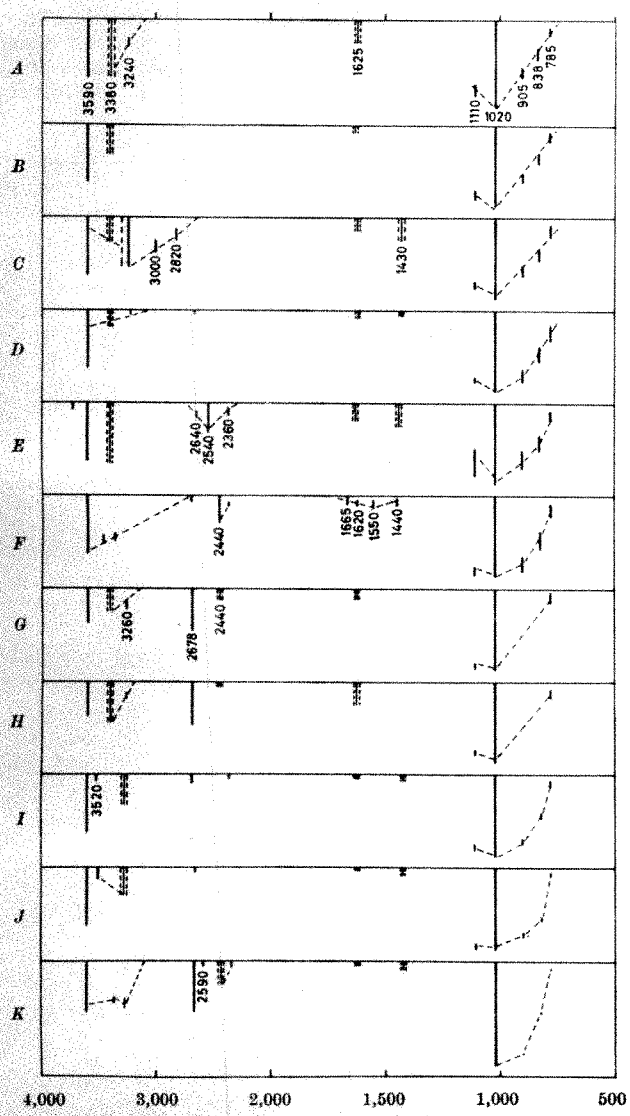

Fig. 1. *A*, Ca^{+} montmorillonite, untreated, air-dried; *B*, sample *A* heated for one day at 420° C in air; *C*, NH_4^{+} montmorillonite heated to 60° C in air ($pH_2O \approx 5$ mm Hg); *D*, NH_4^{+} montmorillonite heated to 420° C in air ($pH_2O \approx 5$ mm Hg); *E*, $Ca^{+}H_2O$ montmorillonite after 14 days in D_2O, saturated atmosphere, room temperature; *F*, $ND_4^{+} - D_2O$ montmorillonite dried above P_2O_5 for one week; *G*, ND_4^{+} montmorillonite heated to 420° C in dry air; *H*, sample *G* after one day in H_2O saturated atmosphere, room temperature ($pH_2O \approx 20$ mm Hg); *I*, sample *H* heated for one day at 420° C in air ($pH_2O \approx 5$ mm Hg); *J*, sample *H* heated for one week at 420° C in moist air ($pH_2O \approx 5$ mm Hg); *K*, ND_4^{+} montmorillonite heated to 420° C in dry oxygen-free N_2

White and Burns[5], who described a similar contraction by introduction of Li^{+} into the vacant octahedron of muscovite.

As a conclusion we arrive at the concept that the protons of hydrogen montmorillonite in anhydrous state form OH partly with the basal O's and partly migrate towards apical O's forming OH's in the vacant octahedrons. The basal OH's are able to dissociate, entering ion exchange reactions, whereas the extra apical (octahedral) OH's are not exchangeable. Thus we have had the following transformation:

$$Ca_{0.25}X_2Y_4O_{10}OH_2 \rightarrow (NH_4)_{0.5}X_2Y_4O_{10}(OH)_2 \rightarrow X_2Y_4O_{9.5}(OH)_{2.5} \rightarrow Ca_{0.18}X_2Y_4O_{9.86}(OH)_{2.14}$$

Dioctahedral hydrogen montmorillonites consequently seem to form structures corresponding to those previously reported for dioctahedral hydrous micas, namely, mixed crystals between $KAl_3Si_3O_{10}(OH)_2$ and $H_2OAl_3Si_3O_9(OH)_3$.

The absorption at 3,260 cm^{-1} in the heat-treated montmorillonites (Fig. 1, *I* and *J*) is the same as reported by Serratosa[6] for rehydrated montmorillonites. In our case it is shown that the band appears although no dissociation of water from the OH groups had yet taken place. The strong bathochromic shift of the OH band could be due to another modification of the lattice obtained by a rotation of the $A\begin{matrix}OH\\OH\end{matrix}Al$ planes, bringing some OH's in more favourable position for hydrogen bonding against O, or because of a disorder in the octahedron cations as demonstrated by Lindqvist[7] in case of muscovite:

AlAlAl□□Al□AlAl□ disorder
AlAl□AlAl□AlAl□ order

The disordered arrangements of the Al's will obviously polarize the O's, diminishing the stretching frequency of the HO band. Similar bathochromic shift is observed in Li-muscovites, and may be the reason for the 3,472 cm^{-1} band of White and Burns[5].

METALLURGY

Poisoning of the Surface of Platinum Metals by Intermetallic Compound Formation

Several years ago[1] it was reported that the platinum metals differed in their relative effectiveness in catalysing the corrosion of less noble metals in boiling acids. The purpose of this communication is to point out that the lowered relative effectiveness of particular platinum metals in the presence of ions of a specific, less noble metal may be explained by the formation of an intermetallic compound on the surface of the platinum metal when it is polarized to a potential close to the corrosion potential of the less noble metal. Quantitative experiments on the system, platinum metal–tin–boiling 2 M hydrochloric acid, are cited to support this point of view.

An extensive series of experiments[2] on the effect of metal ions on the corrosion of tin afforded conclusive evidence that the rate of dissolution of tin in boiling 2 M hydrochloric acid is completely under cathodic control. Thus measurements of the anodic half-reaction (tin dissolution) are in reality measurements of the rate-controlling cathodic half-reaction (hydrogen evolution).

The rate of dissolution of 99·999 per cent pure tin was determined under the following conditions when coupled to a platinum metal exposing the same surface area: (1) directly coupled, tin ions which formed freely bathed platinum metal; (2) coupled externally in separate chambers connected by a diffusion barrier, tin ions added to both platinum metal and tin chambers to a concentration of 0·01 M; (3) coupled externally in separate chambers connected by a diffusion barrier, no tin ions added. The results of these experiments are summarized in Table 1.

The major conclusions to be drawn from these experiments are the following: (1) In the absence of tin ions (column 4) all the platinum metals are very effective in catalysing the dissolution of tin. (2) Platinum and

Table 1

Pt metal coupled to tin	Directly coupled, Sn(II) ions freely bathed Pt metal	Coupled externally, separate chambers, Sn(II) conc. 0·01M	Coupled externally, separate chambers, no Sn(II) ions in Pt metal chamber
	3 (mg/cm²)	3 (mg/cm²)	3 (mg/cm²)
None			
Platinum	160	141	158
Iridium	154	66*	136
Rhodium	46	26	111
Palladium	32	17	162

* This value is not directly comparable with the other values because this set of experiments was carried out, as a result of breakage, in a different reaction vessel, with a higher internal resistance. Evidence obtained from many other experiments indicates that this value should be closer to the value for platinum.

iridium are not seriously poisoned by tin ions in their ability to catalyse the dissolution of tin. (3) Tin ions greatly decrease the ability of palladium to catalyse the dissolution of tin. Quantitative experiments were then carried out on the palladium–tin system.

A sample of palladium exposing a surface area of approximately 1·5 cm² was coupled externally to a tin sample exposing the same surface area in boiling 2 M hydrochloric acid containing 0·0001–0·01 M Sn(II). When the connexion between the palladium and the tin was broken and the potential of the palladium was followed as a function of time on a recording instrument, it was noted that a plateau in the potential decay curve occurred at a potential approximately 50 mV more noble than that of tin in the same medium. Smaller plateaux were also observed at potentials 300–350 mV more noble than that of tin in the same medium. X-ray powder analysis of scrapings from the surface revealed the presence of $PdSn_4$. X-ray diffraction analysis of the surface after the end of the plateau period revealed the absence of $PdSn_4$ and the emergence of a new pattern with strong lines at 2·21, 3·06, 2·87 and 2·29 Å. The compound yielding this pattern was not identified. A sample of palladium on which $PdSn_4$ was formed by coupling to tin was heated in mineral oil at 180° for 17 h. The intense lines in the resulting diffraction pattern were characteristic of PdSn, which is one of the products which might be expected from the thermal decomposition of $PdSn_4$. Corrosion current measurements and kinetic studies of the formation of $PdSn_4$ indicated that this compound begins to form on the palladium surface from the very beginning of the experiment.

Interdiffusion in Zirconium–Aluminium and Zircaloy–Aluminium System

According to Kidson[1], the characteristics of layer growth in a multiphase binary system are influenced considerably by diffusion rate constants of individual phases. The rate constants for various phases differ either on account of differences in crystal structure or due to atomic processes by which diffusion occurs. Zirconium–aluminium system is a multiple phase binary system exhibiting low solid solubility at either ends of a phase diagram. The present note reports certain features of layer growth in zirconium–aluminium and zircaloy–aluminium systems which are presumably affected by the said rate constants.

High-purity aluminium (99·997 per cent) and zirconium (99·9 per cent) were used in the work recorded here. For preparing the diffusion couples, properly cleaned (after Storchheim[2]) Al plugs were tight pressed into holes 0·25 in. in diameter, in zirconium blocks. Prior to insertion, the surfaces of the holes were chemically polished using nitric acid ~ 45 c.c., hydrofluoric acid ~ 10 c.c., and water ~ 45 c.c. solution. In the case of zircaloy, thick-walled 0·25 in. inner diameter tubes were used. The diffusion couples were sealed in silica tubes in vacuum (better than 0·1μ) and later diffusion-annealed at 400°–600° C. The temperature of the furnace was controlled within an accuracy of ± 5° C.

The metallographic and X-ray examination of both zirconium–aluminium and zircaloy–aluminium couples revealed the presence of only two phases in the diffusion zones, which were identified as $ZrAl_3$ and Zr_3Al. The $ZrAl_3$ phase, nearer to aluminium, was found to be relatively more predominant and also more brittle. The presence of only two phases, $ZrAl_3$ and Zr_3Al, out of nine intermetallic compounds reported in phase diagram[3] suggests that the rate constants for the growth of other phases in the system are quite small. Our marker movement investigations showed that the atomic mobility of aluminium atoms is higher than that of zirconium atoms. $ZrAl_3$ lattice is f.c.c. tetragonal (a = 4·013 Å, c = 17·321 Å) with presumably larger interstitial holes. As such the predominance of $ZrAl_3$ in the diffusion layer can be attributed to the interstitial diffusion of aluminium atoms in the $ZrAl_3$ lattice. Zr_3Al has Cu_3Au type ordered lattice (a = 4·372 Å). Hence, assuming diffusion to occur by vacancy mechanism in Zr_3Al lattice, the relative distribution of

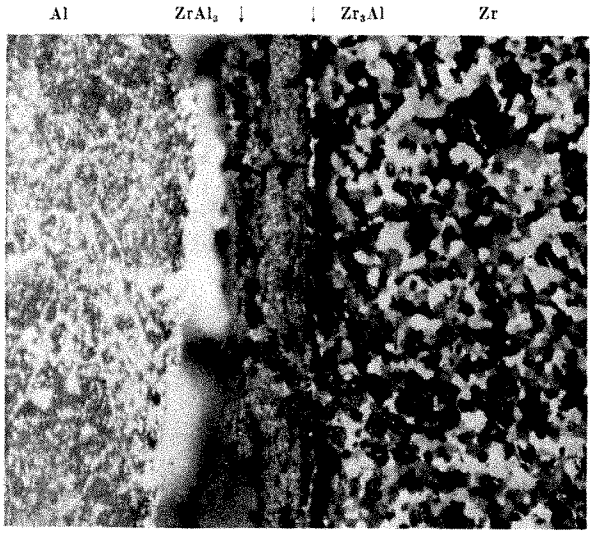

Fig. 1. Distribution of $ZrAl_3$ and Zr_3Al in zirconium–aluminium diffusion couple annealed for 162 h at 600° C (etched and polarized light) (× 120)

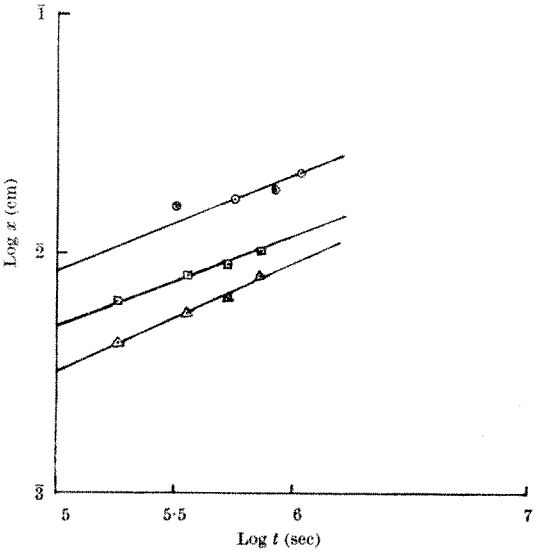

Fig. 2. Log x versus log t plot for zirconium–aluminium system. Diffusion anneal temperature: ○, 600° C; □, 550° C; △, 500° C

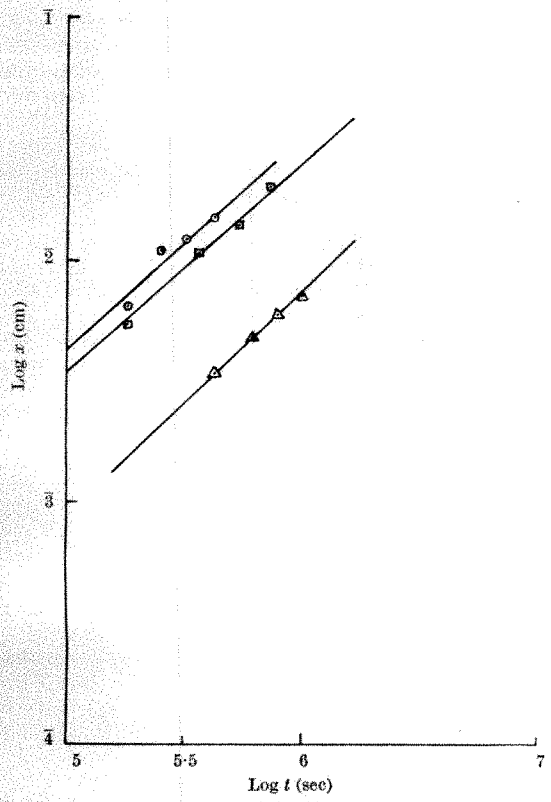

Fig. 3. Log x versus log t plot for zircaloy–aluminium system. Diffusion anneal temperatures: ○, 600° C; □, 500° C; △, 400° C

Zr_3Al and $ZrAl_3$ in diffusion zone can be easily understood (Fig. 1). The rate constants for layer growth could be a factor of miscibility gap or the range over which the phase occurs in the equilibrium phase diagram or the ease with which the mass transfer takes place. It appears that either one or all of these could be responsible for the absence of other phases in the diffusion zone.

Table 1. Showing the Values of n, K and Q for Diffusion of Aluminium in Zircaloy and Zirconium

Zircaloy-aluminium				Zr-Al			
Temp. °C	n	K (cm/sec/units)	Q (kcal)	Temp. °C	n	K (cm/sec/units)	Q (kcal)
600	1·13	$2·11 \times 10^{-8}$		600	2·45	$8·24 \times 10^{-11}$	
500	1·11	$1·7 \times 10^{-8}$	6·74	550	2·49	$4·78 \times 10^{-11}$	7·02
400	1·04	$6·14 \times 10^{-9}$		500	2·21	$3·18 \times 10^{-11}$	

An interesting feature of the interdiffusion of aluminium in zircaloy and zirconium relates to the layer growth. It was noticed that layer growth in zircaloy–aluminium diffusion was comparatively faster. For comparison the total width of the diffusion zone (X) was plotted logarithmically (Figs. 2 and 3) as a function of annealing time (t) by substituting the values in equation $x^n = Kt$, where n and k are reaction index and reaction constants respectively. Any value of $n \neq 2$ represents a deviation from Fick's law and could be characteristic of structural changes occurring in diffusion[4]. Table 1 shows the least square values of n and k for the two systems. (Activation energy for the layer growth (Q) has been obtained by writing the reaction constant $K = K_0 \exp(-Q/RT)$.)

The results seem to indicate faster interdiffusion in zircaloy–aluminium as compared with zirconium–aluminium system. A similar behaviour is reported for tracer diffusion of uranium in zircaloy and zirconium[5]. The Young's modulus for zircaloy decreases more rapidly with temperature[6]. The increased interdiffusion in case of zircaloy could, therefore, be explained due to 'weakening' of elastic bonds in zircaloy as compared with zirconium lattice.

CHEMISTRY

Ferrocene-containing Polymers : Polycondensation of Ferrocene with Aldehydes

After earlier investigations[1] had shown the practicability of self-condensing ferrocenyl carbinols to give polymers containing ferrocenylene units interconnected by methylene or methine bridges, it was of interest to investigate the direct condensation of ferrocene with aldehydes. These components, if used in proper molar ratios, should interact according to equation 1:

with ferrocenyl carbinols and corresponding metallocarbonium ions expected to occur as intermediates, and the resulting polymers should possess structure I:

While, in previous work[2], with benzaldehyde as co-reactant and Lewis acids as catalysts, ferrocene was found to condense smoothly to give I (R = phenyl), aliphatic aldehydes such as formaldehyde and acetaldehyde failed to undergo such polycondensation under the conditions

applied. It has now been found that these aliphatic aldehydes can readily be polycondensed with ferrocene according to equation I if the reactions are conducted in a closed system. The mixture of ferrocene, aldehyde (paraformaldehyde, *s*-trioxane or, most advantageously, dimethoxymethane in the case of formaldehyde) and Lewis acid (preferably zinc chloride; concentrations 3–30 per cent by weight of ferrocene) was heated under nitrogen in a pressure vessel (sealed tube or autoclave) at temperatures sufficiently high to achieve homogeneity of the melt (130°–180°). Suitable work-up by extraction and reprecipitation gave soluble and partially fusible polymers with structures essentially conforming to I (R = H,CH_3) and yields up to 70 per cent. As a result of equilibrium conditions, the average molecular weights attained were generally below 2,500. In a similar manner, crotonaldehyde gave I (R = propenyl); however, yields of soluble polymer were less satisfactory (20–30 per cent) owing to competing cross-linking reactions involving the olefinic double bond.

In the course of this work, the polycondensation behaviour of such other aldehydic reactants as furfural and derivatives of benzaldehyde comprising various side-groups (*p*-hydroxy, *p*-carboxy, *p*-cyano, *o*-methoxy) was also investigated. Here, conditions of atmospheric pressure sufficed, and the resulting soluble polymers exhibited molecular weights up to 5,000 (unsubfractionated). Minor deviations in elemental composition from the expected composition of I were observed in most cases, depending, among other factors, on the steric and electronic effects of the substituent R (equation I) and its propensity toward competing side-reactions. In selected instances cross-linking reactions involving the functional side-groups were accomplished in the presence of diepoxy compounds, leading to insoluble and infusible cured resins.

Photochromism of *p*-Phenylenediaminetetraacetic Acid absorbed in Porous Glass

The compound *p*-phenylenediaminetetraacetic acid, *p*-PTDA (I), can be chemically oxidized to give a blue radical cation (II).

I

II

We have now found that this reaction can be carried out in a novel photochemical manner. When an aqueous solution of the diamine is absorbed by porous glass and irradiated with ultra-violet light, it gives what appears to be the same blue radical-ion species. On interruption of irradiation, the photo-induced coloration rapidly bleaches. Since photochemical reactions leading to reversible colour changes (photochromism) are of fundamental and practical importance, we have undertaken the following investigation of this system.

Aqueous or ethanolic solutions of approximately 0·005–0·06 M *p*-PDTA were absorbed into porous glass 2 mm thick. This glass slowly absorbed solution at atmospheric pressure; however, the process was facilitated by evacuating the glass prior to introducing a solution. Although the entire glass matrix could be saturated, only several tenths of a millimetre penetration were needed to give the results described. Under conditions of normal humidity this glass–diamine system persisted intact for up to 20 min, after which solvent escaping from the pores led to opacification of the sample. The samples could be stored under diamine solution for several days, after which noticeable chemical decomposition occurred.

The porous glass ('Vycor No. 7930', obtained from Corning Glass Works with flat surfaces) was previously cleaned by washing with water and drying at 450° C, using a slow rate of temperature elevation. At least 15 per cent of the volume of this glass is occupied by a continuous network of pores the average diameter of which is 40 Å.

The *p*-phenylenediaminetetraacetic acid[1] was freshly prepared before use as follows: In a vessel under nitrogen flow and heated to 50° C, 0·2 moles of phenylenediamine were slurried in 200 ml. of water. Over a period of 45 min, 1·0 mole of sodium chloroacetate was added with stirring to this mixture, and concentrated sodium hydroxide was intermittently added to compensate for a lowering of *p*H during the course of reaction. For 1 h after completion of chloroacetate addition, sodium hydroxide was added until the *p*H remained constant at 8. While still hot, the reaction solution was filtered under nitrogen and the desired product precipitated with 25 ml. of concentrated hydrochloric acid. After cooling, the precipitate was separated by filtration and washed with a small portion of cold dilute hydrochloric acid followed by washing with acetone. The yield based on phenylenediamine was 86 per cent. The product is a pinkish-white powder which decomposes from 150° to 160° C. Calculated for $N_2O_8C_{14}H_8$: C, 49 per cent; H, 4·71 per cent; N, 8·24 per cent: found, C, 49·5 per cent; H, 4·74 per cent; N, 8·23 per cent.

On irradiation of a 0·01 M aqueous solution of *p*-PDTA absorbed in porous glass with a 'G.E. *RS*-1 Sunlamp' at a distance of 12 in., a change from colourless to blue occurred in 30 sec. The induced change in optical density is shown in Fig. 1. When irradiation was interrupted, this absorption bleached with a half-life of approximately 8 min. An activation analysis showed that coloration was induced by radiation in the 3350–4200 Å region with an activation maximum between 3650 Å and 3950 Å. The coloration

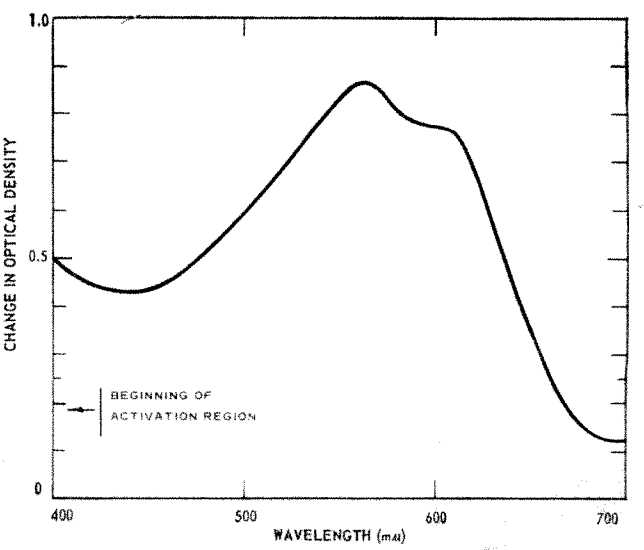

Fig. 1. Change in optical density of *p*-PDTA absorbed in porous glass on irradiation with ultra-violet

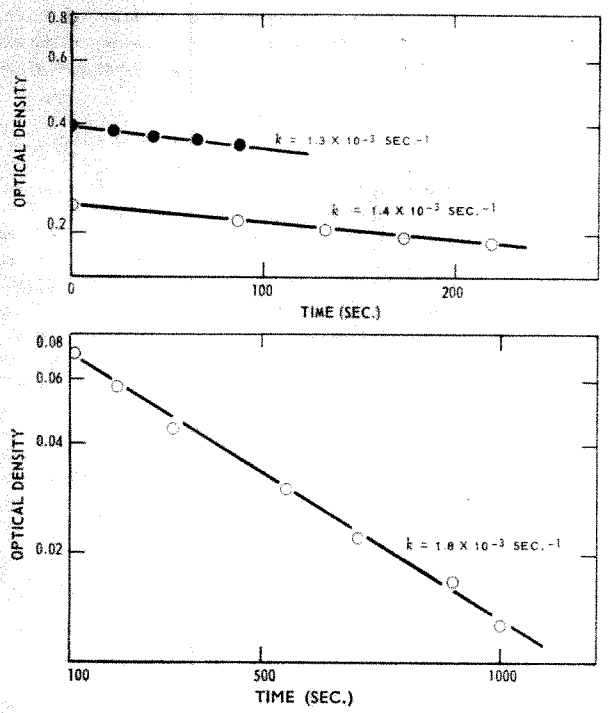

Fig. 2. First-order plots at $\lambda_{max} = 560$ mμ for bleaching of *p*-PDTA absorbed in porous glass. $k_{AVG} = 1{\cdot}5 \times 10^{-3}$ sec^{-1}. $t_{1/2} = 8$ min

and bleaching cycle could be repeated until evaporation of solvent occurred, but, if stored under diamine solution to prevent solvent loss, it could be repeated until chemical decomposition took place (after two days). These results were similar when ethanol was used as a solvent. Also, an aqueous or an ethanolic solution of *p*-PDTA irradiated in the absence of porous glass gave no observable absorption change. These solutions are very slowly attacked by air to give small amounts of the radical cation, especially at *p*H above 2, and care was necessary to avoid this in preparing solutions and fabricating glass samples. Solid *p*-PDTA, which is also susceptible to air oxidation, was freshly prepared before use and stored under nitrogen.

The radiation-induced absorption spectrum shown in Fig. 1 is identical with that of a solution of *p*-PDTA treated with hydrogen peroxide to give its radical cation, structure II, given here. The radical nature of this chemically prepared species was established from electron spin resonance data.

Although it was difficult to reproduce our kinetic results over a diamine concentration range, we did obtain first-order kinetics for the bleaching reaction in several sets of experiments where dilute solutions of *p*-PDTA were used. These results are shown in Fig. 2. Also, as the solutions absorbed in porous glass became more concentrated in diamine, the radiation-induced absorption became slightly lower.

Our results indicate that aqueous or ethanolic solutions of diamine absorbed in porous glass undergo a surface-catalysed photochromic change, that is, are activated by ultra-violet light of 3650–3950 Å and bleach in ambient light. The induced absorption spectrum corresponds to the radical cation of diamine independently prepared and characterized.

Although we conclude that the blue radical cation II is produced photochemically from *p*-PDTA absorbed in porous glass, our experimental results could fit two more specific interpretations for the overall reaction. (1) The diamine in close proximity to the glass matrix may react with ultra-violet light to dissociate an electron which is captured by a matrix centre, and on interruption of the activating light, optical bleaching could occur by electron–radical recombination; or (2) instead of a truly reversible reaction, we could postulate that photo-ionization is followed by radical–radical combination and optical bleaching. Of course, the latter mechanism implies a gradual consumption of active material, but we were not able to test this implication directly due to the fairly rapid chemical decomposition time of the system coupled with the exposure limit created by solvent loss from the glass pores. There are two conflicting pieces of evidence which support the suggested mechanisms: (*a*) bleaching appears to obey first-order kinetics in certain of our experiments; and (*b*) colour development for a given radiation dose becomes lower as the concentration of absorbed diamine increases, indicating the possibility of a self-quenching (radical–radical) mechanism which depletes the product of the forward photo-ionization reaction. We intend to continue this work by establishing a clearer picture of the bleaching reaction mechanism.

We thank Dr. Norma Searle for her activation analyses and Dr. William Hodgson for performing the electron spin resonance investigation.

A Possible Mechanism for the Extra-terrestrial Synthesis of Straight-chain Hydrocarbon

Straight-chain hydrocarbon material[1,2] and long-chain fatty acids[3] have been found in meteorites belonging to the carbonaceous chondrite group. Two possible explanations have been advanced for the origin of this material. Nagy, Meinschein and Hennessy[1] have suggested that it is the result of extra-terrestrial life, since in Nature living processes are the only observed source of linear hydrocarbon molecules. An alternative hypothesis has been proposed by Wilson[4]: that there exists in free space a non-biological mechanism for the synthesis of hydrocarbon in a straight-chain configuration. The proposed mechanism (Fig. 1) involves crowding the reacting chains on to a surface so that only the ends are available for reaction, thus preventing branching.

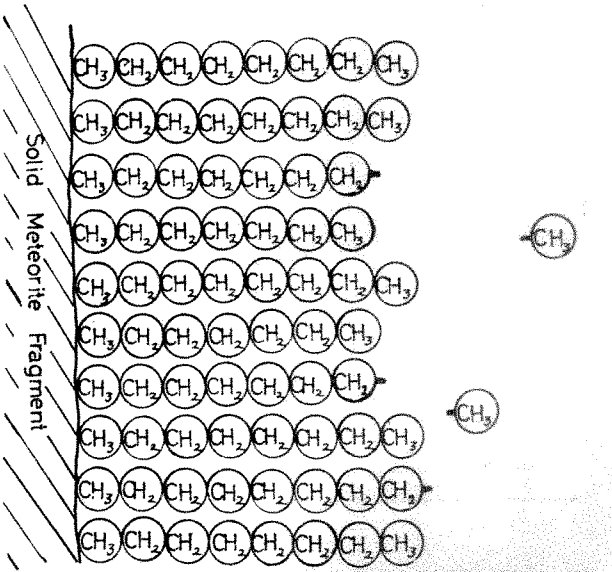

Fig. 1. Proposed mechanism for extra-terrestrial synthesis of hydrocarbon in a straight-chain configuration

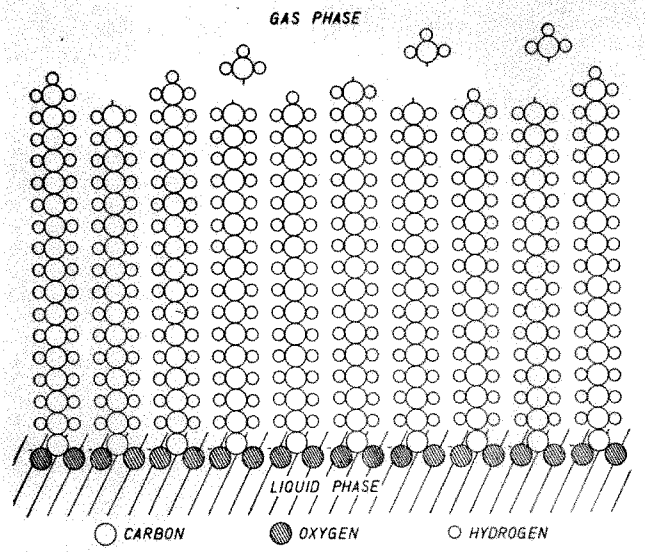

Fig. 2. Proposed mechanism for reaction of methyl radicals with a palmitic acid monolayer on water

The work reported in this communication is a demonstration in the laboratory of the synthesis of linear molecules using this mechanism. Methyl radicals generated by pyrolysis of di-*t*-butyl peroxide[5] were reacted with a monolayer of a straight-chain fatty acid on water, illustrated diagrammatically in Fig. 2.

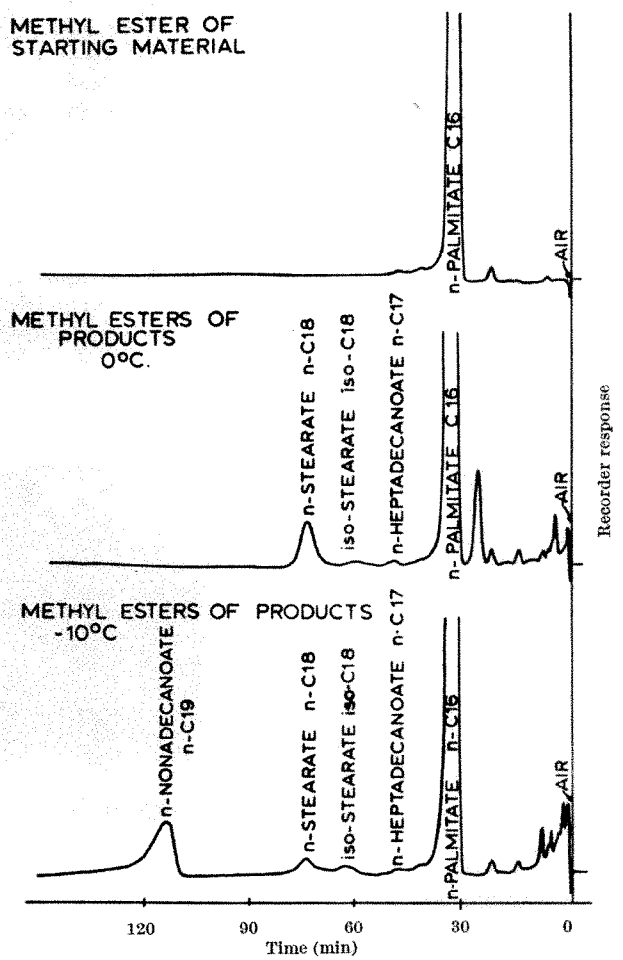

Fig. 3. Gas chromatogram of reaction products—fatty acid methyl esters. Column ¼ in. × 4 ft., packed with 'Apiezon *L*' grease on 80–120 mesh 'Celite' (10 per cent w/w); temperature, 200° C; carrier gas, argon; flow rate, 60 c.c./min; detector, argon ionization

The reaction products were acidified, extracted with petroleum ether, esterified using diazomethane, washed with sodium bicarbonate solution and analysed using a Pye argon gas chromatograph.

Typical results are shown in Fig. 3.

In this experiment it was shown that palmitic acid (n–C_{16}) can be built up stepwise to n-nonadecanoic acid (n–C_{19}) in a 3 per cent overall yield with the production of negligible quantities of branched-chain acids.

Thus it can be seen that it is possible to build up normal hydrocarbon material on a surface by the reaction of methyl radicals with that surface and thus make plausible the extra-terrestrial synthesis of the material on meteorite surfaces as postulated in Fig. 1. The consequences of this type of synthesis have been explored in an earlier communication[4].

We thank Dr. F. B. Shorland of the New Zealand Fats Research Laboratory, Department of Scientific and Industrial Research, for samples of pure fatty acids, and acknowledge financial assistance from the Victoria University of Wellington and the University Grants Committee.

Photolysis of Benzene in *Cyclo*hexane: a Water-soluble Product giving a Positive Thiobarbituric Acid Test

Substances other than malonaldehyde give a characteristic pink coloration on heating with aqueous thiobarbituric acid (TBA). One such substance produced by photolysis of linolenic acid was tentatively assigned an unsaturated carbonyl component[1].

Photolysis of solutions of benzene in *cyclo*hexane produces a water-soluble material, some properties of which have been described[2,3]. Infra-red spectra of the dried material suggest an unsaturated carbonyl component[4]. Paper chromatography and ultra-violet absorption spectra exclude mucondialdehyde, and it has not been possible to correlate the properties of the material with any substances so far described as photolysis or radiolysis products of benzene[4]. It was possible in view of the unsaturated carbonyl assignment that the material might give a positive TBA test; this has been found.

The benzene was three-times recrystallized 'AnalaR'; *cyclo*hexane (Hopkins and Williams, chromatographic grade) was purified on a 75 cm × 1 cm column of silica gel, purity being assessed by the optical densities at 260, 220 and 200 mμ. A 0·2 per cent solution of benzene in *cyclo*hexane was prepared. Ten ml. were irradiated in an open Petri dish, 9·5 cm diam., with a mercury resonance lamp giving 2537 Å filtered by 2 mm 'Vycor': the intensity at the surface of the solution was 2×10^{15} quanta cm^{-2} sec^{-1}. The solution was stirred. After irradiation, the solution was evaporated in a current of cool air and the almost imperceptible film of residue extracted with 10 ml. of M/100 hydrochloric acid. The ultra-violet absorption spectrum was measured and the TBA test of Waravdekar and Saslaw[5] was applied to half the extract.

A broad absorption band, λ_{max} 278 mμ, increased in intensity with irradiation time, as did the TBA test colour at λ_{max} 531 mμ. There was considerable scatter

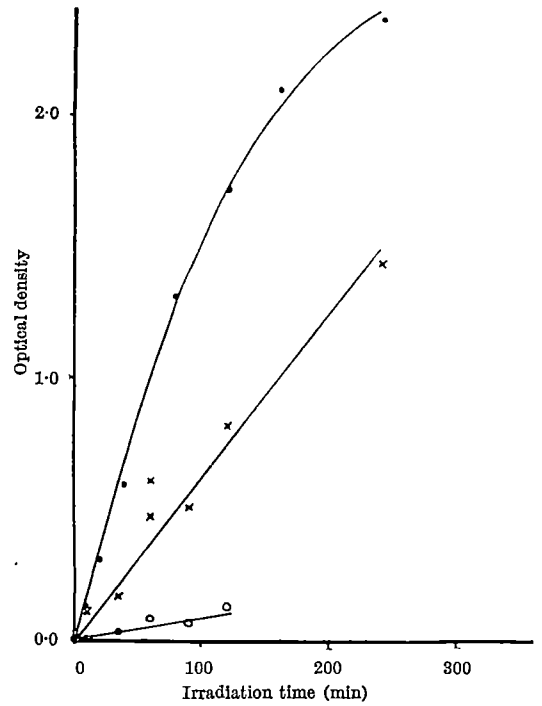

Fig. 1. Production of water-soluble substances absorbing at 278 and 330 mμ and increase in TBA test activity of irradiated solution. (Aliquots of the more concentrated solutions were taken for the TBA test.) ×, absorption at 278 mμ; ○, background absorption at 330 mμ; ●, TBA, test absorption at 531 mμ

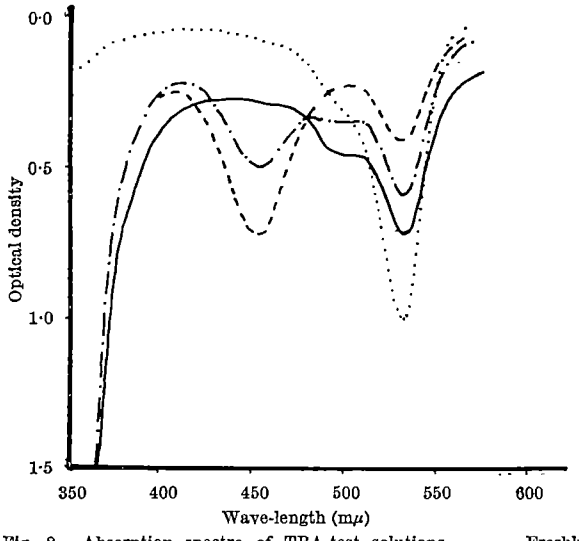

Fig. 2. Absorption spectra of TBA test solutions. ——, Freshly prepared heated solution; — · — ·, similar solution 48 h after preparation; - - - -, different solution, not heated, after 48 h at room temperature; · · · ·, TBA-test from autoxidized linseed oil, heated solution 48 h after preparation, for comparison. Spectra obtained on a Perkin–Elmer 137 ultra-violet spectrophotometer, 1 cm light-path, with water blanks

in the results which was attributed to partial volatility of the photolysis products. If the irradiated solution itself was used for the TBA test, a smooth curve was obtained of TBA test intensity against irradiation time (Fig. 1). (Although there is a correlation with the absorption of extracts at 278 mμ, the non-selective absorption at longer wave-lengths also increased slightly and the TBA-positive material may not be that giving the absorption maximum.)

The freshly-prepared TBA test solution from the photolysis products has λ_{max} 531 mμ but also shows a shoulder at 496 mμ; if the solution is allowed to stand for 24 h, a further maximum appears at 454–56 mμ. It has been shown that peroxides in hot acid solution produce a coloured derivative of TBA which is not a condensation product but has a similar absorption spectrum to the malonaldehyde–TBA product; it was suggested that the TBA test should be performed in neutral solution at room temperature for 15 h (ref. 6). The benzene photolysis product does not oxidize acid potassium iodide, but when the TBA test is thus applied no colour is produced in 15 h; at 48 h the intensity at 531 mμ is about half that of the freshly heated solution. In this aged solution the maximum at 454–56 mμ is much more intense than that at 531 mμ.

To summarize, the material produced by photolysis of a solution of benzene in *cyclo*hexane gives a positive TBA test; this, however, may not be due to a condensation with the unsaturated carbonyl component detected in the dry residue. Side reactions producing additional maxima in the TBA test also occur. This chemical relationship may increase the possibility that there is a connexion between the untested suggestion that benzene products may act as co-carcinogens in the carcinogenic aqueous extracts of photolysis of 3 : 4-benzopyrene in benzene solution[4,7,8] and the demonstration that the aqueous extract of ultra-violet irradiated linolenic acid induces hyperplastic changes in the liver[9].

I thank Dr. J. M. Nosworthy for gifts of three-times recrystallized benzene. This work was supported by the British Empire Cancer Campaign for Research.

Rapid Reaction of Lime with Hydrous Alumina

Calcium aluminate hydrates have recently been reported to form as products of reaction between aluminium-bearing clay minerals and calcium hydroxide at or near room temperatures[1,2]. The investigation recorded here was initiated to determine whether hydrous alumina would react with calcium hydroxide under similar conditions.

Hydrous alumina ('pseudo-boehmite') was prepared by treating a 1 N solution of aluminium chloride with sodium hydroxide, the neutralization being carried out to *p*H 7. The resulting precipitate was washed repeatedly with water to remove the salt formed. The hydrous alumina yielded very weak, broad X-ray diffraction bands at spacings corresponding approximately to several of the strong peaks of boehmite ($Al_2O_3 \cdot H_2O$); however, the ignition loss after oven-drying corresponded almost exactly to that required for the composition $Al_2O_3 \cdot 2H_2O$. A high surface area is characteristic of this material, one such preparation yielding a surface area of 270 m^2/g by adsorption of water vapour. Differential thermal analysis of the dried material revealed broad overlapping endothermic responses with peak temperatures at about 220° and 400° C.

It was observed that mixtures of dried hydrous alumina and calcium hydroxide underwent a very rapid reaction when moistened. The X-ray diffraction peaks for calcium

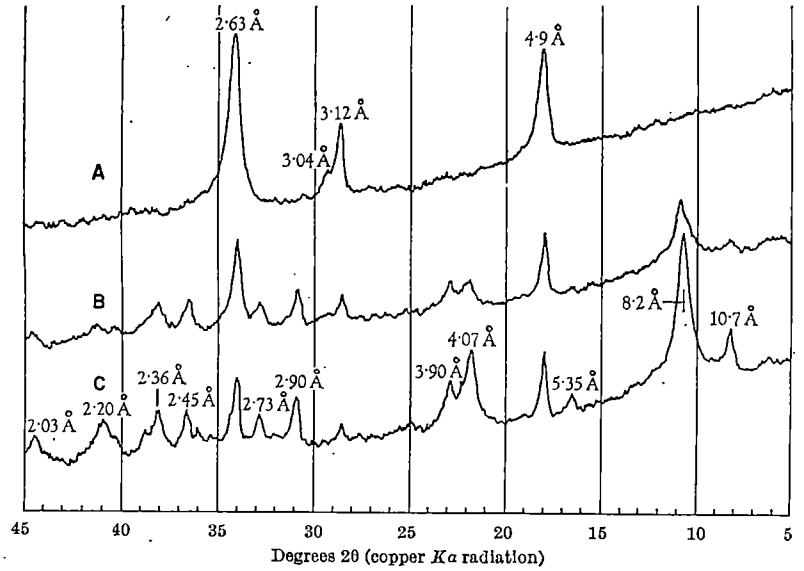

Fig. 1. X-ray diffractometer traces of calcium hydroxide–hydrous alumina preparations. *A*, Dry mixture; *B*, same mixture after wetting, X-ray scan begun 10 min after addition of water; *C*, same mixture 24 h after addition of water

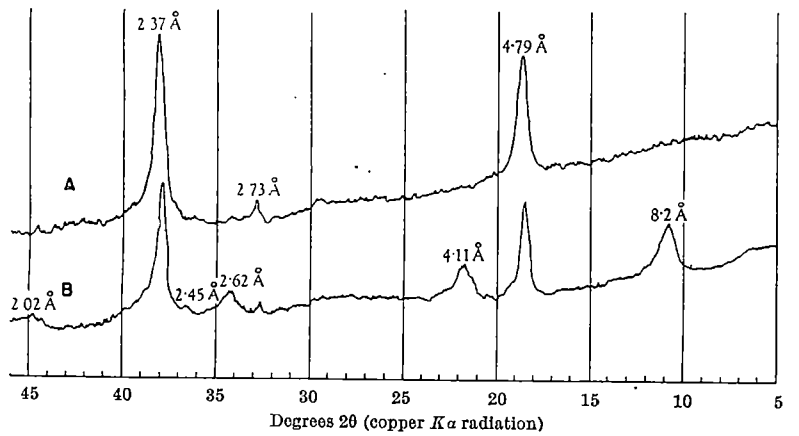

Fig. 2. X-ray diffractometer traces of magnesium hydroxide–hydrous alumina preparations. *A*, Dry mixture; *B*, same mixture 120 h after addition of water

hydroxide were immediately reduced or disappeared completely (depending on the proportion of calcium hydroxide in the mixture). Simultaneously, a new peak appeared at about 8 Å. Within a few minutes a complete X-ray diffraction pattern for the compound $4CaO{\cdot}Al_2O_3{\cdot}13H_2O$ appeared, and the intensities of these peaks continued to increase for some hours. It was observed that if the calcium hydroxide was present in excess, substantial decreases in the intensities of the calcium hydroxide peaks were confined to the first few minutes after moistening the dry mixture, suggesting that the reaction with the hydrous alumina is completed almost immediately. The additional increase in the intensity of X-ray diffraction pattern for the product beyond this short interval is thought to be attributable to progressively improving crystallinity. X-ray diffractometer tracings of a typical mixture before wetting, 10 min after wetting, and 24 h after wetting are given in Fig. 1.

The reaction does not require a large amount of water; in one instance a dry mixture set aside in a corked vial for several weeks was observed to have reacted appreciably, presumably through the agency of moisture adsorbed from the laboratory atmosphere while being mixed.

When a dry mixture is generously moistened (of the order of 50 per cent water by weight of solids), the product formed usually displays X-ray diffraction peaks at 10·7 Å and 5·35 Å in addition to those for $4CaO{\cdot}Al_2O_3{\cdot}13H_2O$. These peaks indicate the formation of some tetracalcium aluminate hydrate in the higher hydration state characterized by the composition of $4CaO{\cdot}Al_2O_3{\cdot}19H_2O$[3]. Occasionally in these experiments additional peaks were observed indicative of the formation of the cubic calcium aluminate hydrate $3CaO{\cdot}Al_2O_3{\cdot}6H_2O$. Seligmann and Greening[4] have directed attention to the ready interconvertibility of this compound and the hexagonal $4CaO{\cdot}Al_2O_3{\cdot}19H_2O$.

Two distinct polymorphic varieties of $4CaO{\cdot}Al_2O_3{\cdot}13H_2O$ have been described, the α-phase being marked by a (001) spacing of 8·2 Å, the β by a spacing of 7·9 Å[3]. In repeated trials in the present work both varieties have been observed to form. Alegre[5] concluded that these polymorphic varieties readily transform to each other depending on temperature and relative humidity; in contrast, Seligmann and Greening maintain that the α-form is in reality a solid solution incorporating a definite proportion of atmospherically derived carbonate, and that it does not spontaneously transform to the β-polymorph. The present products do incorporate some carbonate, the reagent grade calcium hydroxide used containing traces of carbonate observable in infra-red analysis. Furthermore, when the reaction is carried out in the ambient atmosphere additional carbonate is probably incorporated into the product. Nevertheless, the very rapid reaction between hydrous alumina and lime was found to proceed in an apparently identical fashion in a pure nitrogen atmosphere, suggesting that atmospheric carbonation is an accidental rather than an intrinsic feature of the reaction process.

Calcium hydroxide contaminated with traces of carbonate often shows remarkably strong infra-red adsorption maxima at about 1410 and 1470 cm^{-1}. Hunt[6] interpreted both of these maxima as being derived from the ν_3 vibration of the carbonate group, which usually appears at about 1430 cm^{-1}. He attributed the fact that two peaks are observed instead of one to the supposition that this normally degenerate vibration undergoes a loss of its degeneracy in the asymmetrical environment characteristic of the surface location of the adsorbed carbonate. In the work recorded here it was found that after reaction with hydrous alumina these two maxima were replaced by a single sharp maximum at about 1410 cm^{-1}. This might be interpreted as a restoration of the degeneracy of the vibration as a result of the incorporation of the carbonate within the lattice of the newly formed calcium aluminate hydrate.

Another noteworthy feature of the infra-red spectrum of the product is the appearance of a new and fairly strong adsorption band at about 3100 cm^{-1}. If this band is attributed to an OH stretching vibration, as seems reasonable, its low frequency suggests that some of the OH groups of the product are very strongly H-bonded.

Examination of the product by differential thermal analysis revealed the presence of three strong, sharp endothermic peaks at 110°, 235°, and 330° C. These were followed by a small exotherm, and finally the endothermic response marking the dehydroxylation of calcium hydroxide at 540° C. These peaks presumably are indicative of

the complex sequence of thermally-induced rearrangements in $4CaO{\cdot}Al_2O_3{\cdot}13H_2O$ which were reported by Buttler, Dent-Glasser and Taylor[7].

It has been determined that a reaction somewhat similar to that described above takes place between wetted mixtures of hydrous alumina and magnesium hydroxide. In this case the reaction is not rapid, the X-ray diffraction peaks for the new phase becoming evident only after several hours and slowly increasing in intensity over a period of several days. This product is apparently a double hydroxide of magnesium and aluminium. The X-ray pattern observed (Fig. 2) is very nearly identical with that given by Feitknecht and Gerber[8]. The present product yields a (001) spacing of 8·2 Å, which is slightly higher than the 7·9 Å spacing reported by these authors and the 7·95 Å and 7·63 Å spacings reported for different magnesium–aluminium double hydroxide preparations by Mortland and Gastuche[9].

I thank J. L. White, W. L. Dolch and E. B. Kinter for their advice.

Structures of Polymyxin *B*2 and Polymyxin *E*1

FROM the degradative investigations of Suzuki *et al.*[1], and finally by its synthesis[2], the structure of polymyxin *B*1 has now been established as (I): (R = (+)-6-methyloctanoyl, X = D-Phe), in which each of the six αγ-diaminobutyric acid units is of the L-configuration[1,3].

(I; 7α)

Suzuki *et al.*[4] have also shown that the structure of colistin *A* is identical with that of polymyxin *B*1, except that the D-Phe in the latter is replaced by D-Leu (that is, 1; R = (+)-6-methyloctanoyl, X = D-Leu).

From the partial acid hydrolysate of polymyxin *B*2 by fractionation on 'Dowex 50', using gradient elution with ammonium formate–ammonium acetate buffers, we have now isolated and identified the following peptides:

6-methylheptanoyl$\xrightarrow{\alpha}$L-DAB ; Thr$\xrightarrow{\gamma}$DAB ; Thr$\xrightarrow{\alpha}$DAB ;

D-Phe→L-Leu ; Leu$\xrightarrow{\alpha}$DAB ; DAB→Phe ;

Thr$\xrightarrow{\alpha}$DAB→DAB$\xleftarrow{\gamma}$Thr ; D-Phe→Leu$\xrightarrow{\alpha}$DAB ;

Thr$\xrightarrow{\gamma}$DAB$\xrightarrow{\alpha}$DAB ; DAB→Phe→Leu ; DAB$\xrightarrow{\alpha}$(DAB)$_n$;

Thr$\xrightarrow{\gamma}$DAB$\xrightarrow{\alpha}$DAB→Phe and Leu$\xrightarrow{\alpha}$DAB$\xrightarrow{\alpha}$DAB

With the exception of the first of these peptides, which is replaced by (+)-6-methyloctanoyl$\xrightarrow{\alpha}$DAB, they are identical with those obtained from a comparable hydrolysate of polymyxin *B*1.

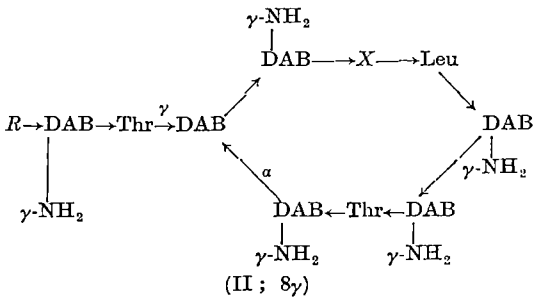
We have also re-examined more thoroughly the partial acid hydrolysate of polymyxin *E*1 and by the procedure outlined above have isolated and characterized the following peptides:

D-Leu→L-Leu ; (+)-6-methyloctanoyl$\xrightarrow{\alpha}$L-DAB ; Thr$\xrightarrow{\gamma}$DAB ;

Thr$\xrightarrow{\alpha}$DAB ; L-Leu$\xrightarrow{\alpha}$DAB ; Leu→Leu$\xrightarrow{\alpha}$DAB ;

DAB$\xrightarrow{\alpha}$DAB→Leu→Leu ; DAB→Leu→Leu ;

Thr$\xrightarrow{\alpha}$DAB→DAB$\xleftarrow{\gamma}$Thr ; Thr$\xrightarrow{\gamma}$DAB$\xrightarrow{\alpha}$DAB→D-Leu ;



Thr$\xrightarrow{\gamma}$DAB$\xrightarrow{\alpha}$DAB ; Thr$\xrightarrow{\gamma}$DAB$\xrightarrow{\alpha}$DAB→Leu→Leu ;

DAB$\xrightarrow{\alpha}$(DAB)$_n$; DAB$\xrightarrow{\alpha}$DAB→Leu ; Thr→DAB→DAB
↑
DAB$\xleftarrow{\alpha}$Thr

Thr$\xrightarrow{\alpha}$DAB$\xrightarrow{\alpha}$DAB→Leu→Leu ; Leu$\xrightarrow{\alpha}$DAB$\xrightarrow{\alpha}$DAB

and Leu→Leu$\xrightarrow{\alpha}$DAB$\xrightarrow{\alpha}$DAB

The re-assembling of each of these two series of peptides in turn indicates that the structure of polymyxin *B*2 is restricted to either (I) or (II) (R = 6-methylheptanoyl and X = D-Phe) and that of polymyxin *E*1 to either (I) or (II) (R = (+)-6-methyloctanoyl and X = D-Leu).

(II; 8γ)

In the determinations of the unequivocal structures of both polymyxin *B*1 and colistin *A* by Suzuki *et al.*[1,4], the differentiation between formulæ (I) and (II) was not forthcoming from the products of partial acid hydrolyses but in each case only by the isolation of the peptide $R\xrightarrow{\alpha}$DAB→Thr$\xrightarrow{\alpha}$DAB by enzymatic hydrolysis. The close relationship between the physical properties of polymyxins *B*1 and *B*2 and their identities in the case of polymyxin *E* and colistin have already been described[5] so that fundamental differences between the structures of these pairs of antibiotics would not be expected, particularly taking into consideration, for example, the difference in optical rotation between the 7α and 8γ-type peptides synthesized by Vogler *et al.*[6]. It is intended to subject polymyxin *E*1 and polymyxin *B*2 to enzymatic degradation to confirm the correctness of structure (I).

Peptizing Action of Some Polar Substances on the Benzene Solution of Cobalt Oleate

We have found that the viscosity of the solution of cobalt oleate in non-polar solvents such as benzene and carbon tetrachloride is unusually high even at low concentrations and, in addition, shows a tendency to increase more and more with time of ageing of the solution, while in polar solvents such as pyridine and chloroform no such reactions have been observed (Fig. 1). The high viscosity found for benzene or carbon tetrachloride solutions of cobalt oleate is to be ascribed to the formation of linear high polymeric structure of cobalt oleate in these solvents. We have also found that the addition of small amounts of certain polar substances to the benzene solution of cobalt oleate decreases its viscosity to almost the value for the solvent alone.

In Fig. 2 is shown the effect of additives (mole ratio to soap 2 : 1) on the viscosity of benzene solution of cobalt oleate. Among various additives the strength of the peptizing action was found in the order: 3,4-dimethylpyridine > pyridine > quinoline > 2,4-dimethylpyridine > 2,6-dimethylpyridine > aniline > chloroform. This order corresponds to that of the tendency for these substances to co-ordinate with a cobalt atom. Water and alcohols were non-effective as peptizers.

The high viscosity of aluminium disoap–hydrocarbon systems was investigated by various workers and the high polymeric structure of aluminium disoap was established[1]. The properties of cobalt oleate–hydrocarbon systems are similar in many respects to those of aluminium disoap–hydrocarbon systems. But the mechanism of the peptizing action of polar substances is apparently different. In the case of aluminium soap, Bauer *et al.*[2] have reported that ethyl alcohol, *m*-cresol and *m*-toluidine are good peptizers, but pyridine and *t*-butyl alcohol are not effective. It has been suggested by these authors that the substances which are capable of forming hydrogen bonds with the carbonyl group are good peptizers for aluminium soaps. However, on the contrary, for cobalt oleate the substances which have strong co-ordinating ability with cobalt atom (for example, pyridines, quinoline, etc.) are very effective peptizers and those which have strong hydrogen bonding ability (for example, water, ethanol, etc.) are not effective.

Cobalt oleate used in this investigation was prepared by metathesis from cobaltous chloride and oleic acid in water–ethanol solution. The composition was $Co_2(C_{18}H_{33}O_2)_3(OH)$. Probably a high polymeric structure will be formed through —OH—Co— linkages. The action of peptizers is assumed to be the destruction of this polymeric structure by co-ordinating with the cobalt atom. We have confirmed this by infra-red and ultra-violet spectroscopy.

BIOCHEMISTRY

A Unique Sugar Orthoester

The isolation and identification of a D-glucose derivative in which the hydroxyl groups at positions C-3, C-5 and C-6 and an *S*-methyl group are commonly linked to form an orthocarbonate-type structure is reported. Such a carbohydrate derivative has not been shown previously.

In previous work[1] we found that *bis*(1,2-*O*-isopropylidene-3-*O*-thiocarbonyl-α-D-glucofuranose) disulphide underwent a rearrangement–fragmentation reaction on standing in various organic solvents to give equimolar quantities of 1,2-*O*-isopropylidene-α-D-glucofuranose 5,6-thionocarbonate (I), 1,2-*O*-isopropylidene-α-D-glucofuranose (IV), carbon disulphide, and free sulphur. The structure of I was proved by its conversion to known compounds and by its independent synthesis. When pyridine solutions of I were treated with acetic anhydride or *p*-toluenesulphonyl chloride, the 3-*O*-acetyl and 3-*O*-*p*-tolylsulphonyl derivatives were formed. In an attempt to prepare the

3-*O*-methyl derivative for subsequent investigations, I was treated in dioxane solution with silver oxide and methyl iodide at room temperature. None of the expected product was formed, but rather 1,2-*O*-isopropylidene-α-D-glucofuranose-3,5,6-(*S*-methyl monothio-orthocarbonate) (II) was isolated as large transparent needles in 54 per cent yield, m.p. 178°–180° C, $[\alpha]_D^{20} - 3{\cdot}3°$ (*c*. 3, chloroform). The structure of II was formulated on the basis of the following experimental findings.

Elemental analysis of II gave: C, 47·8; H, 5·7; S, 11·6, indicating an empirical formula of $C_{11}H_{16}O_6S$, formula weight 276. Molecular weight determination by the Rast method in camphor gave a molecular weight of 280 as an average of three determinations. The infra-red spectrum of II showed no absorption band for a hydroxyl group in the 3,400–3,500 cm^{-1} region. The absence of a hydroxyl was confirmed when an anhydrous ethereal solution of II evolved no hydrogen on treatment with metallic sodium.

Analysis of the ultra-violet spectrum of II at 234 and 288 mμ showed that the $\rangle C{=}S$ group was no longer present. The spectrum of I had absorption maxima at 234 and 288 mμ with respective molar extinction coefficients of 15,000 and 44. When an acetone–water solution of I was treated with silver nitrate, silver sulphide was formed immediately and 1,2-*O*-isopropylidene-α-D-glucofuranose, 5,6-carbonate (III) was recovered from the filtrate in nearly theoretical yield. Similar treatment of II gave no silver sulphide confirming the absence of the $\rangle C{=}S$ group in this product. Desulphurization of I and II with Raney nickel gave IV in yields exceeding 90 per cent.

Compound II exhibited a behaviour characteristic of orthoester-type structures[2] when treated under alkaline and acidic conditions. Accordingly, when an aqueous–acetone solution of II was treated with 5 per cent barium hydroxide solution under reflux for 30 min, only unchanged starting material was recovered. Treatment of I under similar conditions produced a sulphur-free product. When II was treated with 0·01 N hydrochloric acid at room temperature, a strong odour of methyl mercaptan was immediately detected. Following neutralization with silver carbonate, evaporation of the filtrate under reduced pressure gave III, identified by its infra-red spectrum, m.p., and mixed m.p. with an authentic sample. The methyl mercaptan evolved on nitric acid hydrolysis of II in chloroform was determined quantitatively by a slight modification of the procedure of Malisoff and Anding[3]. Under such conditions, 1·0 mole of II gave 0·98 mole of methyl mercaptan. The presence of one alkyl sulphide group per mole of II was also shown by titration of II with a standard solution of potassium bromate in acetic acid[4].

Examination of a Dreiding stereomodel of II reveals a rigid, strained molecule basically comprised of two 1,3-dioxolane rings; one oxolane ring (the furanose ring); and one 1,3-dioxane ring. One of the 1,3-dioxolane rings forms a bridge structure with the 1,3-dioxane ring where the orthocarbonate carbon is the bridgehead atom bonded to three oxygens and one sulphur.

A Polysaccharide resembling Alginic Acid from a *Pseudomonas* Micro-organism

A *Pseudomonas* micro-organism isolated from the sputum of a patient with cystic fibrosis produced unusually large mucoid colonies on agar culture media. This *Pseudomonas*, identified as No. 8906 by us, tended to revert to a less mucoid form and occasionally demonstrated phage plaques. The mucoid *Pseudomonas* was grown on Oxoid sensitivity test media. The bacterial growth was scraped from the surface of the media, and a yield of 664 mg of crude polysaccharide was obtained by initial precipitation with ethanol, followed by extraction with 0·01 N potassium hydroxide at *p*H 10 and repeated precipitation from aqueous solution with 68 per cent ethanol containing 1 per cent sodium acetate.

At a concentration of 0·5 per cent of the polysaccharide, a very viscous aqueous solution was obtained. Analyses showed only insignificant amounts of hexoses[1], hexosamines[2], phosphate and protein. A small amount, about 5 per cent, of nucleic acid was shown to be present by measuring absorption at 260 mμ. Analyses for uronic acid are shown in Table 1. The polysaccharide appeared to be a polyuronide and was insoluble in weak acid. The carbazole to orcinol ratio of 0·20 suggested the presence of mannuronic acid[3]. Because of the similarity to alginic acid, a commercial sample of this polyuronide (K. and K. Laboratories, New York) was also analysed.

Small samples of alginic acid and the crude polysaccharide were hydrolysed in 88 per cent formic acid for 5 h at 98° C, aliquots chromatographed on paper in a pyridine–ethyl acetate solvent[4], and the spots developed with anisidine reagent[5] (Fig. 1). The hydrolysate of the *Pseudomonas* polysaccharide showed spots corresponding to mannuronic and guluronic acid and one corresponding to mannuronolactone. The same results were obtained when the hydrolysates were chromatographed in a butanol–acetic acid solvent[6]. No additional spots could be detected when chromatograms were sprayed with aniline[7], silver nitrate[8] or ninhydrin reagents.

Table 1. Uronic Acid Analysis*

	Carbazol[11] (%)	Orcinol[12] (%)	Carbazole/Orcinol
Crude polysaccharide	8	41	0 20
Alginic acid	18	83	0 22
Purified polysaccharide	18	92	0 20

* Glucuronic acid is used as a standard.

The chemical analyses and the paper chromatography indicated no significant constituents other than uronic acids; but lower values were obtained for the uronic acid colour reactions for the unknown polysaccharide than for the commercial alginic acid. Therefore, the following procedures were carried out on the crude polysaccharide.

Equivalent weight by potentiometric titration was found to be 214, indicating a uronic acid content of 80 per cent. A small amount of the sodium salt of the *Pseudomonas* polysaccharide was dissolved in water and the solution acidified with 1·0 N hydrochloric acid. The gelatinous precipitate which formed was collected by centrifugation, washed with water, ethanol, ether and dried. The yield was 75 per cent, but no change in analyses could be detected.

Infra-red spectra of the polysaccharide sodium salt and of sodium alginate are shown in Fig. 2. No major differences between the polysaccharides in either intensity or position of the peaks were observed. About 25 mg of the crude polysaccharide were purified by precipitation with cetylpyridinium chloride[9]. The analysis of the material, obtained in a 65 per cent yield, is shown in Table 1. Despite the doubling of the orcinol value, no changes in either intensity or position of infra-red peaks could be detected. Several explanations for this and the foregoing results are possible: (1) A substance which had interfered with the colour reaction had been removed during purification. (2) The colour reaction was unreliable, due to

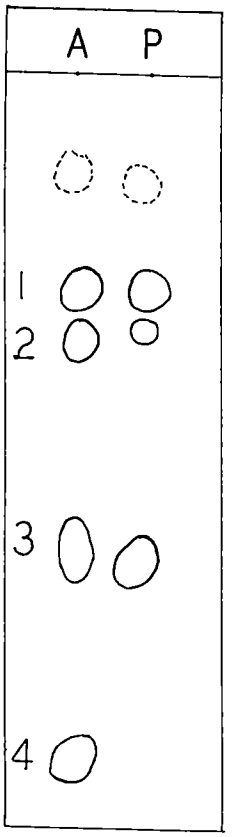

Fig. 1. Tracing of paper chromatogram of acid hydrolysates. All spots showed the red colour, typical for uronic acids, with the anisidine spray. *A*, alginic acid hydrolysate: 1, D-mannuronic acid, 2, L-guluronic acid, 3, D-mannurono lactone, 4, L-gulurono lactone; *P*, *Pseudomonas* polysaccharide hydrolysate

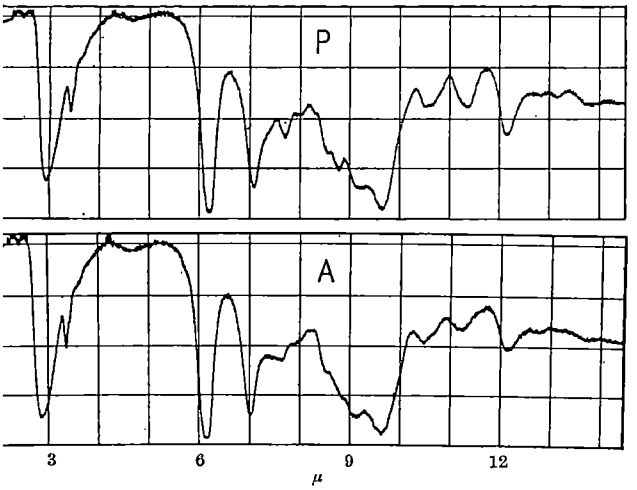

Fig. 2. Infra-red spectra of polysaccharides. *A*, sodium alginate; *P*, sodium salt of *Pseudomonas* polysaccharide. The spectra of the samples (1 mg) in potassium bromide pellets were run on a Perkin–Elmer model 21 spectrophotometer

either the high molecular weight of the polymer or glycosidic linkages different from alginate. (3) A uronic acid-containing polysaccharide not giving the colour reactions was removed by cetylpyridinium fractionation.

The results presented show the production, by a pathogenic *Pseudomonas* organism, of a polysaccharide very similar to alginic acid, a polyuronide usually obtained from brown seaweed. Both mannuronic and small amounts of guluronic acid appear to be present. In this connexion it is of interest that another strain of *Pseudomonas* has been found to degrade alginic acid[10].

The presence of the polysaccharide-producing organism in a patient with cystic fibrosis or mucoviscidosis is of unknown significance, but the thick mucoid secretions in the bronchi would not be improved by the presence of a bacterial polysaccharide which is insoluble in acid solutions and cannot be degraded by endogenous enzymes.

Isolation of Methylcobalamin from Natural Source Material

Investigation of the form of vitamin B_{12} in human blood plasma by chromatographic-bioautographic analysis revealed as the major component a 'fourth factor' besides *DMB* coenzyme (coenzyme B_{12}) and traces of hydroxocobalamin and cyanocobalamin[1]. This factor was also found in liver, *E. coli* and *Streptomyces rimosus*. In order to identify this analogue we have tried to isolate it from a natural source material rich in coenzyme B_{12} and have found good evidence that this analogue is methylcobalamin. Methylcobalamin was prepared by partial synthesis a couple of years ago[2] and was shown by Guest *et al.*[3] to be active in the enzymatic synthesis of methionine by extracts of an *Escherichia coli* mutant. However, methylcobalamin has not previously been shown to occur naturally.

All operations were carried out in the dark or in dim light and all vessels were covered with black cloth or metal foil.

An alcoholic extract of cells from a commercial preparation, kindly supplied by Glaxo Research, Ltd., Greenford, Middlesex, containing about 500 mg of coenzyme B_{12}, was concentrated in an evaporator under reduced pressure to a final volume of 4 l. and until no ethanol remained. From this aqueous solution the vitamin B_{12} analogues were extracted and then displaced from phenol back into water by addition of acetone and ethyl ether (according to Barker *et al.*[4]). After removal of phenol, and concentration, the solution was adjusted to *p*H 5·0 with 0·1 M hydrochloric acid and was passed through a '*CM*-cellulose-Na^+' column (20 cm × 4 cm). The non-adsorbed B_{12} analogues were again purified via phenol and the aqueous solution was concentrated to 3 ml. 3 ml. of normal-butanol and 2·1 ml. of isopropanol were added and this mixture was passed through a column of cellulose 25 cm high × 4·5 cm diam., equilibrated with *n*-butanol, isopropanol and water (10:7:10). The chromatogram was developed with the same solvent mixture and two fractions were collected. Everything moving faster than *DMB* coenzyme (which was the main B_{12} analogue in the preparation) was collected in fraction 1 and the clearly visible zone of *DMB* coenzyme in fraction 2. An equal volume of ethyl ether was added to each fraction and the water-phases were collected and concentrated by evaporation. Paper chromatographic examination showed that fraction 1 contained one fast moving

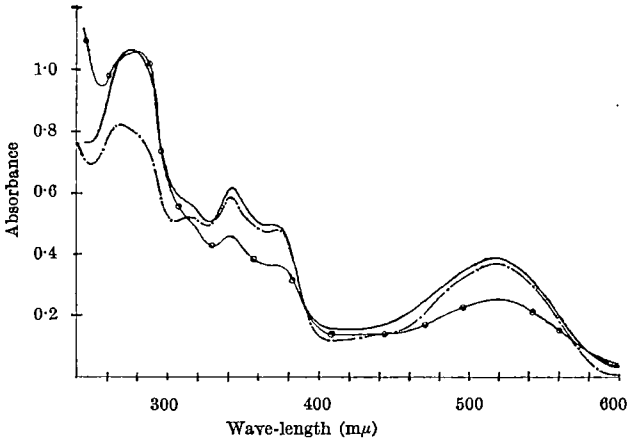

Fig. 1. Spectra of crystalline methylcobalamin (— · —); coenzyme analogue from micro-organism (—); coenzyme analogue from calf liver (—○—)

red compound and a little *DMB* coenzyme. Fraction 2 was mainly *DMB* coenzyme.

Fraction 1 was further purified by adjustment to *p*H 5·0 and passage through a 5 cm × 1·0 cm column of 'Dowex 50*W* × 4-Na$^+$'. The effluent was adjusted to *p*H 10 and was washed through a 'Permutit *FF*-OH$^-$' (strongly basic) column (5 cm × 1·0 cm). The effluent was purified via phenol and the aqueous solution concentrated to a few μl. It was then chromatographed on paper with *n*-butanol, isopropanol and water (10:7:10). The paper was dried and the coenzyme analogue (about 1 mg) eluted with water and again concentrated by evaporation to a small volume.

Calf liver was processed in a similar manner except for some additional purification steps and gave a very small yield of the same substance.

Paper chromatographic investigation in two different solvent systems (I, *n*-butanol, isopropanol and water, 20:7:10; II, *sec*-butanol, acetic acid and water, 100:3:50) gave R_F values for all the preparations including the 'fourth factor' from blood plasma corresponding to that of methylcobalamin. Electrophoresis at *p*H 6·5 showed that the coenzyme analogue had moved the same distance as methylcobalamin.

The spectra of preparations from both micro-organism and liver in water solution (Fig. 1) are in good agreement with the spectrum of crystalline methylcobalamin made by partial synthesis. Both preparations, and methylcobalamin, change colour from red to yellow on acidification of aqueous solutions. The intensity of absorption in the 260 mμ region, relative to that of longer wavelengths, is not great enough to accommodate a purine moiety, so that the 'fourth factor' cannot be derived from *DMB* coenzyme.

The natural occurrence of methylcobalamin is not surprising since Guest *et al.*[3] have already found it to be active in enzymatic synthesis of methionine. It seems unlikely, however, that this is its main function in the human blood stream. Our findings may, on the other hand, help to elucidate the much discussed functional relationship between folic acid and vitamin B_{12}.

PHARMACOLOGY

Inhibition of Phenylquinone-induced Writhing by Narcotic Antagonists

Since nalorphine was demonstrated to have potent analgesic properties[1,2] and to be non-addicting in man[3], a considerable effort has been directed towards finding narcotic antagonists with similar activities, but without the undesirable psychotomimetic effects produced by nalorphine[4]. This effort has been complicated by the fact that nalorphine not only is inactive in most analgesic tests in animals, but also will antagonize the analgesic activity of most narcotic drugs[5]. Only the rat flinch-jump test of Evans[6] has been reported capable of detecting the analgesic activity of nalorphine. This finding, however, has yet to be reported by other workers.

Recently, a series of benzomorphans with narcotic antagonist activity[7] also has been shown to possess potent clinical analgesic efficacy[8,9]. These compounds, too, were found inactive in several animal analgesic tests[7]. One of them, cyclazocine, was shown to increase the aversive shock threshold of trained monkeys, but nalorphine was found to be inactive in the same procedure[10].

The work recorded here has demonstrated that the phenylquinone writhing test[11] is a sensitive indicator of the analgesic activity of narcotic antagonists. Using the method of Hendershot and Forsaith[12], groups of five male *CFW* mice (19–21 g) were injected intraperitoneally with phenylquinone (10 ml./kg of 0·025 per cent solution) 15 min after the subcutaneous administration of the test drugs. The mice were then placed in an observation beaker, and the number of 'writhes' (arching of the back and hind-limb extension) per animal was counted during a 10-min period starting 5 min after the phenylquinone treatment. At least two groups of five animals each were used for each dose, and the total number of writhes for each dose as compared with the total number of writhes for a saline-treated control group was used for calculating the percentage protection. The mean and standard deviation for 72 saline-control groups, representing 360 mice, was 98·8 ± 17·0. Using the method of Litchfield and Wilcoxon[13], the dose–response curves were plotted and the ED_{50}'s and relative potencies were determined. The drugs compared were: morphine sulphate, nalorphine hydrochloride, cyclazocine ('*WIN* 20740', 2-*cyclo*propyl-methyl-2′-hydroxy-5,9-dimethyl-6,7-benzomorphan) and pentazocine ('*WIN* 20228', 2′-hydroxy-5,9-dimethyl-2-(3,3-dimethylallyl)-6,7-benzomorphan).

Both nalorphine and the two benzomorphans were potent antagonists of phenylquinone-induced writhing in mice (Fig. 1 and Table 1), and seemed active in the same order of potency as seen in man[8,9], that is, cyclazocine > nalorphine > pentazocine. An estimate of the relative potency of these drugs with respect to morphine could not be made because of significant differences in the

Table 1. Comparison of the Phenylquinone Antagonism of Morphine and Narcotic Antagonists

Drug (subcutaneous route)	ED_{50}	95% confidence limits	Slope
Cyclazocine	0·10	(0·04–0·28)	10·0
Morphine	0·45	(0·27–0·77)	2·4*
Nalorphine	0·92	(0·33–2·6)	9·0
Pentazocine	2·00	(0·67–6·0)	8·8

*Statistically significant difference from all other slopes ($P = < 0·05$).

Table 2. Correlation between Phenylquinone Antagonism and Clinical Analgesic Potency

Drug	Mice ED_{50} (mg/kg)	Mice Relative potency	Human clinical dose (mg/kg)	Ref.
Cyclazocine	0·01	10·0	0·004	9
Morphine	0·10	1·0	0·11	2, 8, 9
Nalorphine	0·12	0·8	0·13	2
Pentazocine	0·20	0·5	0·14–0·28	8

All doses calculated in terms of mg/kg of free base ; human doses calculated on basis of 70 kg man.

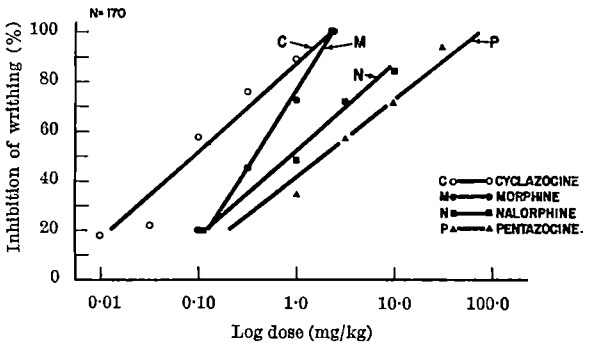

Fig. 1. Phenylquinone antagonism of morphine and narcotic antagonists

slope of the dose–response curves (Table 1). However, when the drugs are compared at a point (ED_{20}) where morphine and nalorphine are equi-effective, as has been shown in man, both the relative potency and the actual mg/kg doses seem highly correlated with established clinical results (Table 2).

The dissimilarity between the narcotic antagonists and morphine, both in the spectrum of activity in other analgesic tests and the slope of the dose–response curve in this procedure, suggests that the antagonists may, in part, exert their analgesic effect through a mechanism different from that of morphine. At present, we are investigating the effects of various combinations of morphine and nalorphine on the writhing response to phenylquinone in an attempt to elucidate these differences further.

We thank Dr. S. Archer, of Sterling-Winthrop Laboratories, for the supply of cyclazocine and pentazocine.

Inhibition of Uridine Ribonucleotide Synthesis by 5-Halogenated-2′-deoxyuridine Analogues

Previous *in vitro* research[1] with the halogenated analogues of orotic acid demonstrated the following basic experimental facts: First, to inhibit the conversion of orotic acid to the uridine nucleotides it was necessary for a drug to be a 5-substituted analogue of orotic acid. For example, it was found that 5-fluoro-orotic acid would inhibit orotic acid conversion, but that 5-fluoro uracil would not. Second, the order of activity of the 5 halogenated orotic acid analogues was fluorine > chlorine > bromine, and the 5-iodo compounds showed little or no activity.

The systems used in the research reported here used a high-speed supernatant fraction from rat brain (20 per cent homogenate in 0·25 M sucrose centrifuged at 114,000*g* for 1 h) as the enzyme source. This preparation will convert either orotic acid or uracil to the uridine nucleotides, the end-product being predominantly UTP. The reaction mixtures contained phosphoglyceric acid, $6{\cdot}6 \times 10^{-3}$ M; $MgCl_2$, $5{\cdot}0 \times 10^{-3}$ M; KH_2PO_4, $3{\cdot}3 \times 10^{-3}$ M; ATP, $3{\cdot}3 \times 10^{-4}$ M; (6-^{14}C) orotic acid, $1{\cdot}0 \times 10^{-4}$ M; or (2-^{14}C) uracil, $1{\cdot}66 \times 10^{-5}$ M; with ribose-5-phosphate, 2×10^{-3} M; or ribose-1-phosphate, $1{\cdot}3 \times 10^{-3}$ M; with the orotic acid and uracil systems respectively. The reactions were carried out at 37° C for 90 min and chromatographed on 'Dowex-1-formate' columns as described in a previous communication[2]. The brain was used as a source of enzyme because both the orotic acid and uracil pathways are operative in this tissue.

Table 1 demonstrates the activity of a number of 5-halogenated-2′-deoxyuridine analogues against both the uracil and orotic acid systems. It is evident that practically all the compounds tested had significant activity against the uracil system in 60 : 1 drug/metabolite ratio. It is noteworthy that thymidine and deoxyuridine both had marked activity. When the drug concentration was lowered to a 6 : 1 drug/metabolite ratio only thymidine and the iodo-, chloro-, and bromo-derivatives retained their activity.

Table 1. Inhibitory Effect of Deoxyuridine Antimetabolites on Uridine Ribonucleotide Synthesis by Brain High-speed Supernant Fraction

Uracil system	Drug/metabolite ratio	% Inhibition of conversion to uridine nucleotides 60 : 1	6 : 1
Thymidine		64·6	18·6
2′-deoxyuridine		72·3	0·0
5-fluoro-2′-deoxyuridine		79·8	0·0
5-iodo-2′-deoxyuridine†		92·0	31·2
5-iodo-uridine		78·7	0·0
3,5-diacetyl-5-iodo-2′-deoxyuridine†		94·1	57·0
5-chloro-2′-deoxyuridine		*	32·6
5-bromo-2′-deoxyuridine		*	27·5

Orotic acid system	Drug/metabolite ratio	10 : 1
Thymidine		0·0
5-fluoro-2′-deoxyuridine		0·0
5-iodo-2′-deoxyuridine		0·0
3,5-diacetyl-5-iodo-2′-deoxyuridine		0·0
5-chloro-2′-deoxyuridine		33·0
5-bromo-2′-deoxyuridine		0·0
Deoxyuridine monophosphate		6·3
Thymidine monophosphate		33·3

* Indicates that the drug was not tested at this concentration.
† Obtained through the courtesy of International Chemical and Nuclear Corporation, City of Industry, California.
All drugs listed under orotic acid system were inactive at a 2 : 1 ratio.

The orotic acid system is much less sensitive to these agents; only thymidine monophosphate and 5-chloro-2′-deoxyuridine showed any significant activity. All drugs were inactive at a 2 : 1 ratio. It should be pointed out that phosphorylation of the deoxynucleoside analogues in the orotic acid system is minimal, and that the deoxynucleotides of these analogues would be better test agents.

The order of activity of these halogenated derivatives against the uracil system is reversed from that of the 5-halogenated orotic acid analogues mentioned earlier, in that iodine > bromine > or chlorine, with fluorine showing the least activity. It should also be noted that normal deoxyribose metabolites inhibited this system. The inhibition of ribonucleotide synthesis by deoxynucleotides has been shown previously[3]. There is a possibility that the 5-halogen substituted compounds used here may exert their effect through a similar mechanism.

It cannot be said if the action reported here can be correlated with the known inhibitory action of 5-iodo-2′-deoxyuridine against herpes infections of the cornea[4]. However, the actions demonstrated here could be expected to inhibit protein synthesis in tissues which are partially dependent on uracil utilization rather than orotic acid for uridine nucleotides. The high drug/metabolite ratios used in this work are not unrealistic in view of the high concentrations of 5-iodo-2′-deoxyuridine used in the local

treatment of herpes. Experiments utilizing corneal epithelium are in progress.

HÆMATOLOGY

Dizygotic Twins with XX/XY Chimerism

CHIMERAS, dizygotic twins who have two populations of blood cells, arise when hæmatopoietic cells are exchanged or shared at some time in early embryonic life. The first case of chimerism in man was reported by Dunsford *et al.*[1].

The twins here reported are clinically normal male and female infants. They had a single dichorionic placenta with no obvious anastomosis of the surface blood vessels. Chimerism was discovered by blood grouping of the red cells of the twins by the Rh Laboratory of Winnipeg. Two red-cell populations were found in the same proportion in each twin, approximately 85 per cent being group O and the rest group A. The inherited ABO types were established by testing the saliva: the boy was group A and the girl group O. Details of the blood group investigations have been reported elsewhere[2].

Peripheral blood samples were obtained for chromosomal investigations. Karyotype analyses of 100 cells of each twin revealed normal chromosome complements except for the presence of numerous cells in the male twin with a female karyotype and some cells in the female twin with a male karyotype in the following proportions: 70 XX : 30 XY cells in the male and 78 XX : 22 XY cells in the female twin. The parents and sib have normal karyotypes. These proportions are similar to, and probably not significantly different from, those found for the red-cell populations.

The phenomenon of chimerism is best known in cattle, and was first described by Owen[3]. The sterility of the female chimera is believed to be caused by androgens circulating in the common placental vascular system. Cattle chimeric twins have been observed to have the same proportions of each of the two types of blood irrespective of their genotype. This suggests that each twin has drawn its primordial blood cells from a common pool rather than having received the foreign cells by partial exchange[4].

Among marmosets chimeras are even more common than among cattle since 87·5 per cent of births are reported to be twins, the majority of which are suspected to be dizygotic[5]. Extensive placental anastomoses between dizygotic twins are present but freemartins are unknown. The actual proportions of the two types of red blood cells in marmosets are not known. However, Benirschke *et al.*[6] have demonstrated by bone marrow culture that in one female and two males the cells were chimeric with respect to the sex chromosomes. In each case the major population of cells was its own.

There have been occasional reports of vascular anastomoses in human dichorionic placentæ[7]. However, in a series of 409 fused dichorionic placentæ (238 isosexual and 171 heterosexual twins) examined by injection of the blood vessels, we have found no instance of a vascular communication. This suggests that such intercommunication is a rare event. On the other hand, it is possible that a vascular communication could have existed some time in early embryonic life and disappeared during later development.

With respect to the blood group types, the previously reported human chimeras are similar to marmosets in that the major proportion of cells corresponds to the genotype of the individual. Chromosomal analyses in the only case studied gave frequencies of XX and XY cells consistent with the blood group proportions[8,9]. These twins are unmarried. Two other female chimeras have produced children[1,10]. The present pair of twins differs from the other human chimeras and from marmosets but resembles cattle in the proportion of blood types.

Alkaline Phosphatase Activity of the Leucocytes in Animals

THE study of alkaline phosphatase activity in neutrophilic leucocytes has become a useful tool in clinical laboratory work. Although the practical usefulness of the test has been demonstrated, the significance of differences in activity in different conditions is still obscure.

A convenient histochemical method has been described by Kaplow[1]. Since many factors influence the outcome of the test, it is important to have a positive control when examining the blood of unknowns. It has been found that pregnant women have increased alkaline phosphatase activity of the leucocytes[2] and therefore they can always be used as positive controls. However, pregnant women are not always available or the maternity wards may not be convenient to the laboratory.

The work recorded here had the following objectives : (*a*) to find laboratory animals with constant and physiological high alkaline phosphatase activity of the leucocytes, which can be used as positive control any time in the laboratory; (*b*) to contribute to the understanding of this enzyme metabolism in leucocytes.

Using the method of Kaplow[1], I examined 157 laboratory animals of different species, hamsters, rats, mice, guinea-pigs, rabbits and monkeys. In rabbits, guinea-pigs and monkeys, the blood can easily be obtained from the ear, while in hamsters, mice and rats it is easier to get it from the tail. The scoring was carried out in duplicate in the first 37 animals, but after it had been found that the duplicate findings were rather close to each other, this practice was discontinued.

The hamsters, rats, mice, guinea-pigs and rabbits were adult and healthy, and reared in the laboratory. Some were young unmated adults, others had one or more litters. None was pregnant. The results are shown in Table 1. In 53 normal healthy men and women we

Table 1. Alkaline Phosphatase Activity of the Leucocytes in Animals

Species	No. examined	Sex	Age (months)	Mean score	Range
Guinea-pigs	31	M 16 F 15	1–7	311·5	251–351
Hamsters	27	M 13 F 14	1½–7	335·8	231–392

Total	55 (M 30, F 25)	Pos. 29, neg. 26		

* M, male; F, female.

found a mean score of alkaline phosphatase activity of 10·3, with a range of 3–65. Compared with the findings in man, there is a definite increase of alkaline phosphatase activity in the leucocytes of guinea-pigs, hamsters, rabbits and rats. Especially in guinea-pigs and hamsters the alkaline phosphatase activity of the leucocytes is extremely high. Nearly all neutrophilic leucocytes look dark-brown or black. Since, in man, a high alkaline phosphatase activity of the leucocytes is often associated with leucocytosis, we performed the total white blood cell count in 6 guinea-pigs and 3 hamsters. It was not increased in comparison with the count found in man. It was interesting to see that the leucocytes in mice were devoid of alkaline phosphatase activity. The lack in alkaline phosphatase activity in the leucocytes of mice on one side and the high activity in those of guinea-pigs and hamsters on the other side is so striking and constant that their blood can effectively serve as negative and positive controls respectively, when stained at the same time as unknown smears. No definite difference was found between the scores in males and those in females. Since hamsters, guinea-pigs and rabbits are found in most laboratories, this will be of great help to those examining alkaline phosphatase activity in leucocytes.

The group of monkeys included different species. Some of them were healthy, others were infected with various forms of malaria. They ranged in age between eighteen months and three years except two baby *M. nemestrina* monkeys who were 5 months old. It is interesting to find that different species showed entirely different alkaline phosphatase activity of the leucocytes. The activity seems to be more dependent on the species than on the health condition of the animals. In the *Macaca iris*, *M. nemestrina* and *Hylobates* spp. the enzyme activity is very high in healthy as well as in malaria-infected animals. There was no significant difference between the mean scores of monkeys with and without malaria. The leucocytes of the *M. mulatta*, however, were devoid or nearly devoid of all alkaline phosphatase activity, also in those most heavily infected with malaria. In fact, in all *M. mulatta* monkeys examined the leucocytes were found to be devoid of any alkaline phosphatase activity, except in one which had a score of 11. No significant differences in activity were found between male and female animals.

This investigation demonstrates that in animals genetic factors play an important part in the metabolism involving the enzyme alkaline phosphatase in leucocytes. It is possible that genetic factors also play a part in human beings in certain conditions.

Similar interesting differences in metabolism involving glucose-6-phosphate dehydrogenase in red blood cells have been shown in closely related animals[3].

I thank Mr. Lau Kheng Khuan of the animal house, Institute for Medical Research, and Dr. M. Warren and Dr. Gordon Bennet of the Far East Research Unit, U.S. Public Health Service (Kuala Lumpur), for their co-operation.

Changes in the Human A Antigen of Erythrocytes with the Individual's Age

The human A and B antigens on fœtal red cells are weaker than those on erythrocytes of adults and undergo marked quantitative changes during life. Reports describing these changes appeared in the literature as early as 1929. Morville[1] stated that in most instances the A and B antigens seemed to have reached maximal strength by the time the child was four months of age. However, according to Thomsen and Kettel[2], the strength of the antigens increased more slowly, and maximal values were not reached until 15–20 years of age, afterwards remaining constant. This view was challenged by Lodenkämper and Stienen[3], who provided data indicating that the A and B antigens reach maximal strength at one or two years of age and remain at this level to 30–40 years of age; thereafter the strength of the antigens decreases and approaches zero. Obviously, these reports disagree with respect to the age at which the A and B antigens reach adult strength, and they also disagree as to the strength of these antigens in old age.

A quantitative investigation of the sources of variation within the human A blood types has provided evidence bearing on this question of age and antigen strength. It is this evidence which is summarized in the present communication.

Type A blood samples were obtained from three different sources: (1) from all A_1 individuals tested during the period from November 1, 1962–December 31, 1963, in a population investigation; (2) from families selected for having an infant with ABO hæmolytic disease of the new-born; but young infants who had suffered severe neonatal hæmolytic disease are not included. These families were ascertained from the records of the University Hospital in Ann Arbor, Michigan; (3) cord blood samples of type A_1 infants born to A_1 mothers delivered in the Maternity Clinic of the University Hospital. All individuals from the different sources were Caucasians. Since the strength of the A antigen is depressed in the presence of B, AB individuals were not included.

The strength of the A antigen was determined by an immunohæmolytic system which was previously described in detail elsewhere[4]. Briefly, the technique consists of incubating a constant amount of a photometrically standardized cell suspension with a constant amount of hæmolytic rabbit anti-human-A antibody and complement for 90 min at 37° C. After centrifugation, the density of hæmoglobin in the supernatant fluid is determined photometrically and the percentage hæmolysis is taken as a

Table 1. THE STRENGTH OF THE A_1 ANTIGEN IN RELATION TO THE AGE OF INDIVIDUALS

Age (years)	No. tested	Average strength of A_1 antigen	S.D.
Cord cells	30	26·9	6·56
< 2	18	43·3	6·37
2 and 3	19	52·9	5·71
4 and 5	18	53·3	5·69
6–10	88	52·1	6·40
11–15	85	53·4	6·19
16–20	33	53·7	4·03
21–30	53	54·7	5·89
31–40	84	53·9	7·34
41–50	50	53·4	6·35
51–60	29	54·2	5·84
61–90	26	52·2	5·58

measure of antigen strength. Fresh blood samples are essential for reproducible results. Although the sub-type of A could generally be predicted from the hæmolytic test, it was always verified with *Dolichos biflorus* and *Ulex europaeus*.

The results are presented in Table 1. An increase in antigen strength with an increase in the individual's age up to 2 years of age is obvious. The difference in antigen strength between cord cells and children less than 2 years of age is highly significant ($P < 0.001$), as is the difference between children less than 2 years of age and those 2 and 3 years of age ($P < 0.001$). The differences in antigen strength among the age-groups above 2 years of age are relatively small and only the difference between age-groups 6–10 and 21–30 is significant ($P < 0.05$). The cells in the 61–90 age-group were similar in behaviour to those of other adults, both in the immuno-hæmolytic and agglutination tests. The cells of the oldest individual tested, who was 90 years of age, showed 47·5 per cent hæmolysis, a value which is well within the range of younger adults. The sources of variation among type A adults will be the subject of a forthcoming publication.

The values for children up to 4 years of age are plotted in Fig. 1. A freehand curve has been applied to these points to show the average trend in strength of the A_1 antigen with age. The term 'adults' is being used for individuals 6 years of age and older. As the figure illustrates, antigen strength increases very rapidly during the first few months of life up to about 5 months and then increases with slower rate until adult values are reached. The data indicate that there is considerable variation in the age at which the infant's red cell antigen reaches its adult strength, but 2–4 years or shortly thereafter may represent a general average.

For sub-type A_2, similar trends of change in the quantitative aspects of the A antigen were observed, the main difference being that A_2 was weaker than A_1 during all

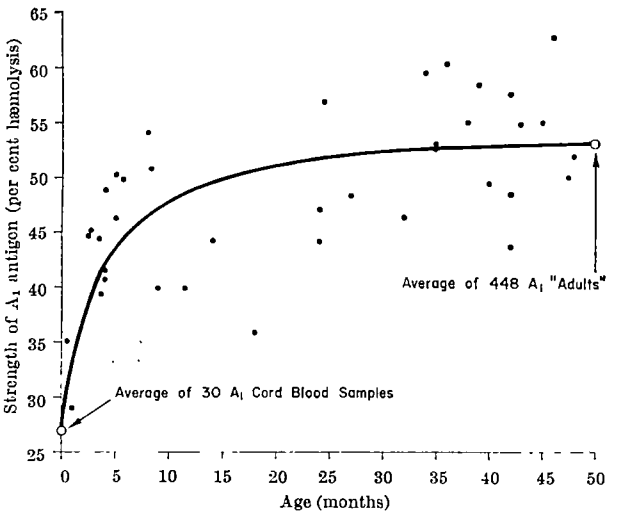

Fig. 1. Change in the strength of the A_1 antigen among infants up to 4 years of age. The dots represent individual values

phases of the individual's life. The B antigen undergoes similar changes, although it has not been investigated here. What will be said in the following discussion regarding A probably also applies to B.

Compared with the previously mentioned reports in the literature, the present findings indicate intermediate values with respect to the age at which the A antigen attains parental strength. That the present values are intermediate may result from the fact that none of the previous authors made any distinction between A_1 and A_2 sub-types, a fact which could have increased the variation in their investigations. Also, different antisera may be responsible for some of the differences in results. The present findings disagree with the conclusion of Lodenkämper and Stienen[3] that A antigen strength decreases to zero in old age. The reason for this discrepancy is not clear. It is known, however, that in rare cases of certain types of leukæmia the A antigen may no longer be present on the red cells of formerly recognized type A individuals[5,6], but it is not known whether or not this was a factor in the investigation of Lodenkämper and Stienen. The results recorded here agree with those of Thomsen and Kettel[2] in showing that the red cells maintain their sensitivity in old persons.

Erythrocytes of cord blood and of new-born infants possess antigenic sites which are not present on the red cells of adults[7,8]. This fœtal antigen is not a property of the Lewis system[7]. The presence of this antigen may be the cause of the relative insensitivity of the A and B antigens of fœtal erythrocytes. This may provide a protective mechanism *in utero* against maternal antibodies in ABO incompatible pregnancies. If fœtal cells were to have adult strength, few A_1 fœtuses would probably remain unharmed in pregnancies of type O mothers. The quantitative aspects of the A antigen as an etiological factor in ABO hæmolytic disease of the new-born have been discussed elsewhere[9].

The change in strength of the A and B antigens may result from a gradual maturation of the erythropoietic system. This maturation may be partly associated with the change in erythropoietic sites which occurs during fœtal life and early infancy. The mesenchyme and then liver and spleen are the main sites of erythropoiesis up to the fifth month of fœtal life, thereafter this function is gradually transferred to the bone marrow, so that at birth erythropoiesis is almost exclusively a function of the bone marrow[10].

Of the human red cell antigens only a few undergo marked changes during the individual's life, while most appear to remain relatively constant[6]. A similar pattern seems to prevail among the bovine red cell antigens. There the J antigen, which is serologically related to the human A antigen, is not present at birth and likewise undergoes changes during life[11]. Although the time of change of the A antigen in man and the bovine J antigen differs, a phylogenetic relationship cannot be excluded.

The evolutionary mechanisms underlying the marked change in the strength of the A antigen are as yet not clear. However, selective forces may have been operative in opposite directions in fœtal life and post-natally. One force may have been towards the selection of a weak fœtal A_1 antigen, thereby reducing the hazards of fœtal-maternal ABO incompatibility. The other force would seem to have been directed towards selection of a strong A antigen in post-natal life. Since a weak A antigen has been favoured in fœtal life, the A antigen would be expected to remain weak to post-natal life. The fact that it does not do so implies that some selective force has favoured a change to a stronger post-natal A antigen. Selective advantage in epidemics, as proposed by Vogel *et al.*[12], or heterotic advantages might be examples of such selective forces. The examination of monkeys and higher primates, such as the baboons, which possess the A and B antigens but not O (ref. 13), may provide some insight into the selective mechanisms concerned.

This work was supported in part by Atomic Energy Commission contract *AT*(11–1) while I held a U.S. National Institutes of Health post-doctoral fellowship (*GPD*–15, 166). I thank Dr. D. C. Shreffler and Dr. H. Gershowitz for making available their blood-typing records. I am also indebted to Dr. D. E. Anderson for his assistance with the manuscript and to Dr. T. N. Evans and his staff for collecting the cord blood samples. A portion of the samples used was made available by the Cardiovascular Research Center, University of Michigan, supported by programme project grant *H*–6378 from the National Heart Institute.

PATHOLOGY

Antigenicity of Trypanosome Nuclei: Evidence that DNA is not coupled to Histone in these Protozoa

The sera of patients with certain diseases (for example, systemic lupus erythematosus) often contain autoantibodies which react with various constituents of cell nuclei[1,2]. We have detected antibodies reacting specifically with free DNA[2,3], DNA-histone[2,4], a saline soluble protein[2,5] and an unidentified constituent of the nucleolus[2,4] in such sera by the fluorescent antibody technique. Most sera from patients with connective tissue diseases contain a mixture of two or more of these antinuclear antibodies, but occasionally a serum may contain only one of them. Monospecific antinuclear sera have proved valuable cytochemical reagents for the tentative identification of the corresponding antigens since they show relatively little species specificity[6], but they have not been used previously to investigate protozoa.

Several strains of trypanosomes were examined. Blood forms were available in smears of blood from rats infected with *Trypanosoma gambiense*, *T. rhodesiense*, *T. rhodesiense* 200, *T. cruzi*, *T. congolense*, *T. congolense K*71, *T. equiperdum*, *T. evansi S.A.K.* and *T. lewisi*. Cultures of *T. rhodesiense*, *T. congolense*, *T. lewisi*, *Leishmania donovani* and *Strigomonas* sp. were suspended in 0·15 M sodium chloride and smeared on slides. Unfixed air-dried preparations were treated for 30 min with monospecific human antinuclear sera in a moist chamber at room temperature to allow the antibody to become attached to its antigen. The unattached human serum proteins were removed by washing in barbitone buffered 0·15 M sodium chloride (*p*H 7·2) for 10 min and thereafter the slides were stained with a fluorescein-conjugated rabbit antiserum to human γ-globulin for 30 min. The slides were then washed and, after mounting in glycerol containing 10 per cent (v/v) barbitone buffer (*p*H 7·2), examined with dark-ground illumination using blue violet/ultra-violet light on a horizontal optical system similar to the instrument designed by Young[7]. Excitor filtration was achieved with a 2·0-cm optical cell containing 10 per cent copper sulphate and a glass mounted Kodak Wratten 18*A* filter; a Kodak Wratten 2*B* gelatin filter was used for absorption of ultra-violet light scattered into the microscope tube. Photographs were taken in colour on high-speed 'Ektachrome' and also on monochromatic Agfa *KB*14 film.

The specificity of the first stage of the staining procedure was controlled by demonstration of absorption with the appropriate antigen and failure of absorption with the other antigens as described previously[4,5], except in the case of the antinucleolar antibody because the corresponding antigen has not been identified.

The non-specific staining properties of the fluorescein-conjugated rabbit anti-human-γ-globulin were removed by absorption with acetone-dried rat liver powder. The specificity of this reagent was then established by absorption experiments in which it was shown that its capacity to stain attached human γ-globulin could be removed by treatment with human γ-globulin (prepared by DEAE 'Sephadex' chromatography of normal human serum) but not by other serum fractions.

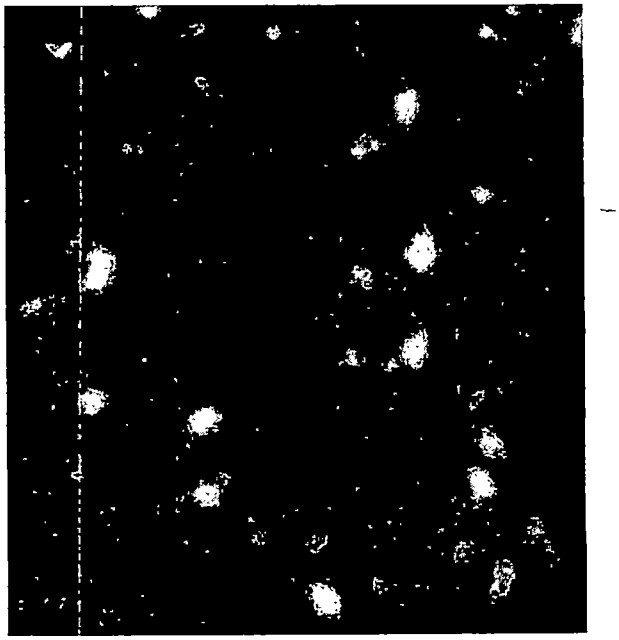

Fig. 1. *Trypanosoma cruzi* in blood film from infected rat: nuclei stained with antinuclear serum containing anti-DNA (× 1,650)

Similar results were obtained with all the trypanosome strains investigated. Trypanosome nuclei were stained by sera containing anti-DNA antibodies (Fig. 1) but they remained unstained after treatment with normal sera or sera containing antinuclear antibodies to other antigens (Fig. 2). The potency of the antinuclear antibodies in all sera used was demonstrated by their ability to stain the nuclei of the host leucocytes in films of the infected blood.

Further investigations of the staining of trypanosome nuclei by sera containing anti-DNA have shown that these sera lose this property after absorption with calf thymus DNA (Worthington Biochemical, Inc.) but remained unaffected after treatment with RNA (Worthington Biochemical, Inc.); in these experiments sera were absorbed for 45 min with 25 mg purified antigen/ml. serum at 37° C. Furthermore, the nuclear antigen with which these sera react was destroyed by pretreatment with DNase (Worthington Biochemicals, Inc.) (0·1 mg/ml.)

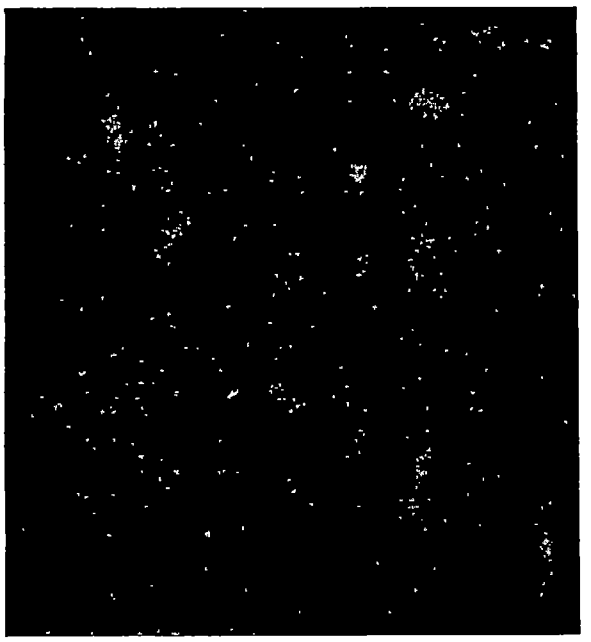

Fig. 2. *Trypanosoma cruzi* in blood film from infected rat: nuclei unstained after treatment with antinuclear serum containing anti-DNA-histone (× 1,650)

in 0·15 M sodium chloride containing 40 μg Mg^{++}/ml. for 1 h at 37° C whereas the antigen was unaffected by treatment with buffer control or with RNase (1·0 mg/ml.) in ion-exchanged water for 1 h at 37° C. These experiments confirm the specificity of staining by anti-DNA sera which has demonstrated DNA antigen in trypanosome nuclei.

The nuclei of all species of trypanosomes investigated were stained with sera containing anti-DNA antinuclear antibody. This staining was immunologically specific since it was prevented by absorption of these antinuclear sera with purified DNA or by predigestion of the antigen by DNase but not by control treatments. This demonstrated that antigenicity of the DNA in trypanosome nuclei was identical with that in higher forms[2]. Stollar *et al.*[8] had shown previously by a complement-fixation technique that similar antigenic determinants for anti-DNA antinuclear sera were present in DNA extracted from normal and neoplastic mammalian tissue, many varieties of bacteria, several strains of bacteriophage, *Euglena gracilis* and tobacco leaf, so that it was not surprising that the present investigation showed that trypanosome DNA conformed to the general biological pattern.

The failure of sera containing antinucleohistone, the potency of which was demonstrated by its reaction with host leucocyte nuclei, makes it highly probable that the DNA of trypanosome nuclei is not present as DNA–histone complexes of the type found in metazoan cell nuclei. Therefore, trypanosome DNA may either be free or it may be combined with a protein other than histone. The first alternative appears more attractive since there is considerable evidence that bacterial and viral DNA are not associated with basic protein[9–11]. The possibility that the DNA is combined with a non-histone protein cannot, however, be excluded since the only previous investigations on protozoal DNA have been concerned with analysis of its base composition[12–15]. There have been indications that the nuclei of trypanosomes circulating in the blood may be in some stage of division[16], but it is unlikely that this will have altered the state of combination of the DNA since it has been shown that in HeLa cells DNA is complexed as nucleohistone in interphase cells and remains so during all stages of mitosis[17].

The failure of the antibody to the saline soluble protein of mammalian nuclei to stain trypanosome nuclei is not surprising as this antigen has not been demonstrated previously in the nuclei from animals other than mammals[4]. Sera containing the antinucleolar antibody failed to stain trypanosome nuclei, demonstrating that the corresponding antigen was not localized in discrete nucleoli. This observation is of interest as structures with the appearance of nucleoli are seen in electron micrographs of trypanosomes, but the nature of these intranuclear inclusions is undecided since no intranuclear RNA staining with acridine orange is seen on fluorescence microscopy[16,18].

All human sera stained the kinetoplast area in all species of trypanosomes investigated, but markedly brighter staining in kinetoplastic forms was produced with sera containing anti-DNA antinuclear antibody than with normal sera, or other antinuclear sera which react with DNA-histone, the soluble protein antigen or the nucleolar antigen. In most species the stained area corresponded in size, shape and position to the kinetoplast, but a similar area of staining was seen in the strain *T. evansi S.A.K.*, in which neither kinetoplasts nor their DNA could be demonstrated with the light microscope at the base of the flagellum[19]. Recent electron microscope investigations have shown that the kinetoplast is a modified mitochondrion containing a band of DNA[20] and that similar structures, lacking only the DNA band, are seen in drug-induced and spontaneously occurring akinetoplastic trypanosomes[21–23]. It is, therefore, probable that in the non-specific staining of the kinetoplast region produced by human serum, the human γ-globulin is attached to the kinetoplast at some point other than in the DNA band, although it must be remembered that the resolution of the optical system used in this investigation is such that it is not possible to localize the staining with great accuracy to the kinetoplast. Alternatively it is possible that this staining has resulted from trapping of human serum in the invagination of the cell membrane at the base of the flagellum which Vickerman[24] has demonstrated close to the kinetoplast.

RADIOBIOLOGY

Protection with 2-β-Aminoethylisothiourea, Glutathione and Serotonin of Mice against Whole-body Irradiation

2-β-Aminoethylisothiourea (AET)[1,2], glutathione[3,4] and serotonin[5], administered separately, have been shown to protect X-irradiated mice. Many attempts have been made to increase the protective action by combining two or more drugs, and we have shown previously that AET in combination with serotonin increases optimal protection offered by either compound alone[6,7]. Results are reported here on the survival of mice treated with glutathione, AET and serotonin prior to exposure to a supralethal dose of X-irradiation.

Groups of C^+ male mice 11–12 weeks old ($LD_{50/30}$ and $LD_{100/30}$, respectively 650 and 900 r.), weighing 25–30 g, received a whole-body dose of 1,350, 1,800 and 2,000 r. of X-rays. The conditions of irradiation were: 200 kV, 10 m.amp, 1 mm aluminium, dose rate in air 100 r./min, target to object distance 54 cm. The mice were exposed in groups of 11 in a partitioned 'Lucite' cage. Times of administration and doses of AET, glutathione and serotonin used in the different experiments are given in Table 1.

Table 1 shows that after a radiation dose of 1,350 r. all the non-treated mice as well as the mice treated with glutathione died within 8 days. 10 per cent of the mice treated with serotonin and 20 per cent of those treated with AET survived after 30 days. 40 per cent of the mice treated with AET + glutathione and 70 per cent of those treated with AET + serotonin were still alive after a 30-day period, whereas 90 per cent of the mice treated with AET, glutathione and serotonin survived the same period of time. The combined treatment with serotonin + glutathione was less effective than the protection offered by the combined treatment with AET + serotonin or AET + glutathione. The mortality curves obtained after a radiation dose of 1,800 r. for treated and non-treated mice is presented in Fig. 1, and a corresponding curve for a dose of 2,000 r. is shown in Fig. 2. It is evident from these curves to what extent combination of AET, glutathione and serotonin increases survival rate and survival time if compared with unprotected mice.

Burnett and Doherty have demonstrated that AET approximately doubles the $LD_{50/30}$ days survival of X-irradiated mice[1]. A similar dose reduction factor for AET protection was observed for damage to bone-marrow[8] and small intestine[2]. Bone-marrow and small intestine are also protected to some extent by serotonin[6,7]. Glutathione administered subcutaneously or orally protects

Table 1. Survival time of C^+ mice treated with AET, glutathione and serotonin given separately or in combination before a whole-body dose of 1,350, 1,800 and 2,000 r. of X-rays

Treatment	Amount of compound (mg)	Route of administration	Time of treatment (min before irradiation)	Dose of radiation (r.)	Medium times of survival (days)	Percentage of survival (30 days)
Control				1,350	5	0
				2,000	4	0
Serotonin*	1	IP+	5	1,350	8	10
Glutathione†	32	OR+	25	1,350	6	0
AET‡	10	OR	25	1,350	10	20
AET	8	IP	15	1,350		70
Serotonin	1		5	1,800		0
Glutathione	32	OR	25	1,350	7	20
Serotonin	1	IP	5			
AET	10	OR	25	1,350	15	40
Glutathione	32					
AET	8	IP	10	1,350		90
Glutathione	16	OR	25	1,800	10	37
Serotonin	1	IP	5	2,000	9	30
AET	8	IP	10	1,350		90

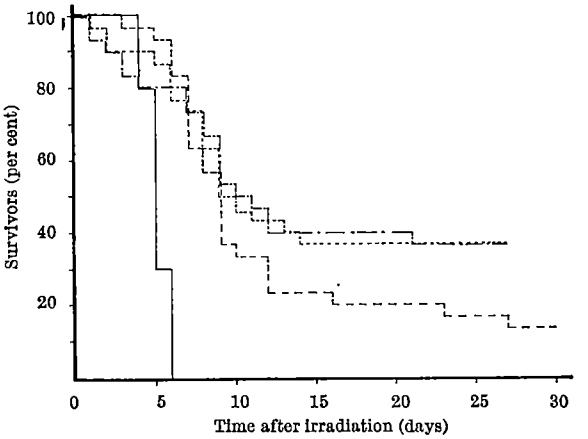

Fig. 1. The protective effect of different combinations of AET + glutathione + serotonin to whole-body X-irradiated C^+ mice with 1,800 r. (30 mice were used per group). —·—, Glut. 16 mg (orally) 25′ + AET 8 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation, 1,800 r.; - - - -, glut. 75 mg (orally) 25′ + AET 8 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation 1,800 r.; — — —, AET 10 mg (orally) 25′ + glut. 32 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation 1,800 r.; ——, X-irradiation 1,800 r.

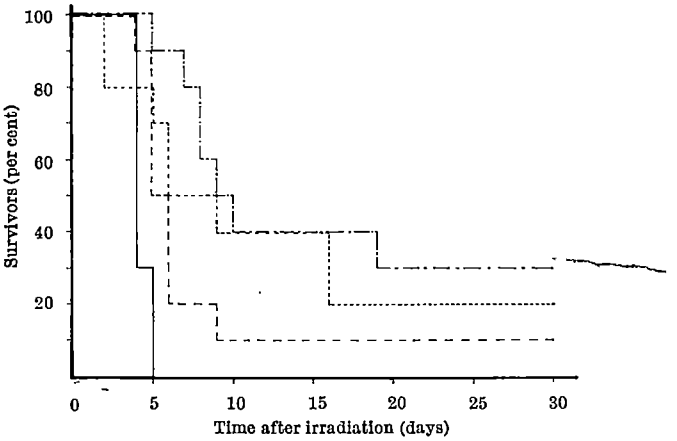

Fig. 2. The protective effect of different combinations of AET + glutathione + serotonin to whole-body X-irradiated C^+ mice with 2,000 r. (10 mice were used per group). —·—, Glut. 16 mg (orally) 25′ + AET 8 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation 2,000 r.; - - - -, glut. 75 mg (orally) 25′ + AET 8 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation 2,000 r.; - - -, AET 10 mg (orally) 25′ + glut. 32 mg (intraperitoneally) 10′ + ser. 1 mg (intraperitoneally) 5′ + X-irradiation 2,000 r.; ——, X-irradiation 2,000 r.

animals against an $LD_{100/30}$ days[3,4]. We have shown previously that combined treatment of AET and serotonin increases the survival of mice irradiated with 1,350 r.[6]. This increased survival time is dependent on the dose of AET and is essentially due to an increased protection to the bone-marrow[7]. Concentrations obtained in the marrow, as well as the dependence of the degree of protection of the combined treatment on the sulphydryl compound levels, suggest that AET and serotonin act through different pathways. Serotonin offers protection, presumably, through local anoxia[9], and AET partly either by a temporary formation of mixed disulphide bonds with sensitive sulphydryl groups of proteins[10,11], or by a radical-trapping action[12,13], or by an inhibiting action on synthesis of DNA[14].

Thus glutathione which alone is not a strong radioprotector becomes a potent supporting agent for the radioprotection due to AET. We do not think that the fundamental mechanisms of action of AET and glutathione are different, but rather that the low toxicity of the latter compound allows the administration of relatively large amounts of glutathione in combination with AET and thus increases the protection of AET. Glutathione could, for example, either increase the time during which AET is available in the cell, or react with certain structures of the cells which are relatively little radiosensitive, but which are capable of binding AET. In this manner more

AET would become available in the cell for action on radiosensitive structures which either do not react with glutathione or are only little protected by it.

Our results show that combined treatment with AET, glutathione and serotonin still offers some protection to mice subjected to whole-body X-irradiation at 2,000 r.

This work was supported in part by a grant from Euratom and the International Atomic Energy Agency.

Note added in proof. An experiment now completed indicates: (1) that the $LD_{100/30}$ days of mice treated with glutathione, AET and serotonin before X-irradiation is 2,200 r., as compared with 900 r. in the controls; (2) that glutathione added to AET or to AET plus serotonin decreases the toxicity of AET.

Oxygen Effect with 14-MeV Neutrons

The modifying effect of oxygen on the biological response to 14-MeV neutrons has been discussed in relation to the use of these neutrons in radiotherapy[1–5]; but no direct experimental data were cited. We have recently obtained for another purpose some data for 14-MeV neutrons on yields of chromatid-type aberrations in meristematic cells of bean root tips in aerated and anoxic conditions. The dose modification factor for true aberrations was about 1·5 and for non-staining lesions ('gaps')[6] about 1·3. These values are very little greater than those found for chromosome damage in the same biological material with 3-MeV neutrons[7] or in *Tradescantia* microspores with fission neutrons[8].

It has been estimated[9] that half the yield of chromosome damage seen with 14-MeV neutrons is due to the α-particles produced by inelastic nuclear reactions[10]. The dependence upon oxygen of the effect of these α-particles should be appreciably less than for the recoil protons, so the comparatively low overall value of oxygen dose modification factor found by us is not unexpected. It seems to be a reasonable presumption that for other biological effects besides chromosome aberration induction the oxygen factor for 14 MeV neutrons should be small and that, as regards oxygen dependence of effect, 14 MeV neutrons should be almost as suitable for radiotherapy as fast neutrons of lower energy.

BIOLOGY

Ultrastructure of the Sensory Hair-cells in the Labyrinth of the Ammocœte Larva of the Lamprey, *Lampetra fluviatilis*

In a previous publication[1] the ultrastructure of the sensory epithelia of the labyrinth of *Raja clavata* was described and brought into relation with what is known of the responses of single sensory cells to angular acceleration, tilting, and to vibrational stimuli. It was found that the compound hair-processes of the sensory cells show a topographic polarization which could in most cases be correlated with the directional functional properties of the receptor cells.

The hair-cells are secondary sensory cells, and as such they synapse with the end branches of the bipolar neurones which constitute the first neuronal stage of the afferent pathway. Synaptic membrane structures were described but there was very little demonstrable evidence for the presence of synaptic vesicles associated with them.

We have now extended our electron-microscopic studies to the labyrinth of the ammocœte larva of the

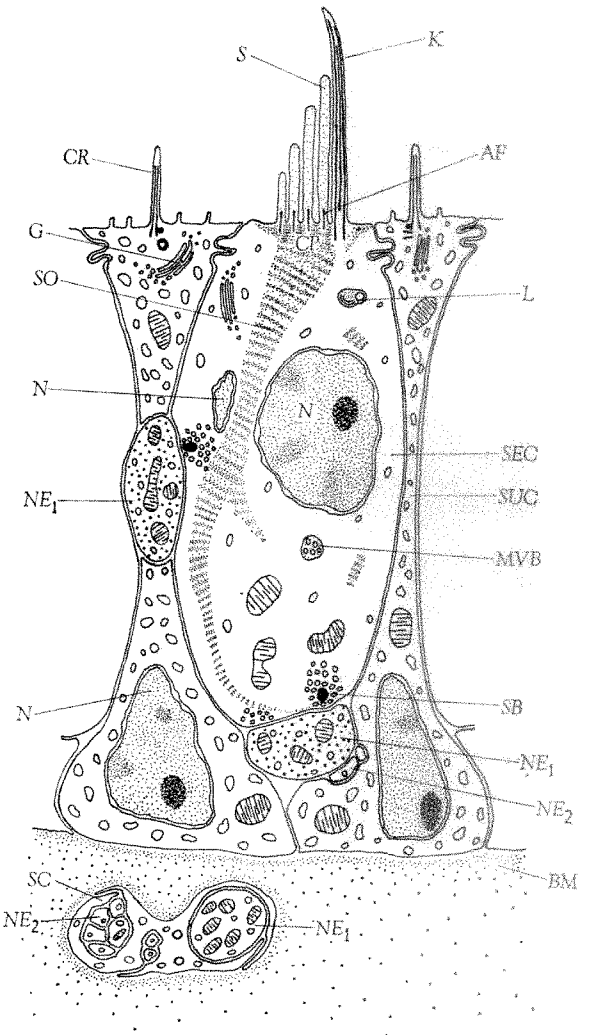

Fig. 1. Schematic drawing of a single sensory cell from a crista of the ammocœte labyrinth. Note the striated organelle which originates from the cuticular plate and runs to the base of the cell where it terminates in close proximity with synapse. Nerve fibres synapse with basal and nuclear regions of the cell. *AF* = axial fibre; *BM* = basement membrane; *CR* = ciliary rod; *CP* = cuticular plate; *G* = Golgi apparatus; *K* = kinocilium; *L* = lysosome; *MVB* = multivescular body; *N* = nucleus; *NE*$_1$ = large nerve endings; *NE*$_2$ = small nerve endings; *S* = stereocilia; *SB* = synaptic bar; *SC* = Schwann cell; *SEC* = sensory cell; *SO* = striated organelle; *SUC* = supporting cell

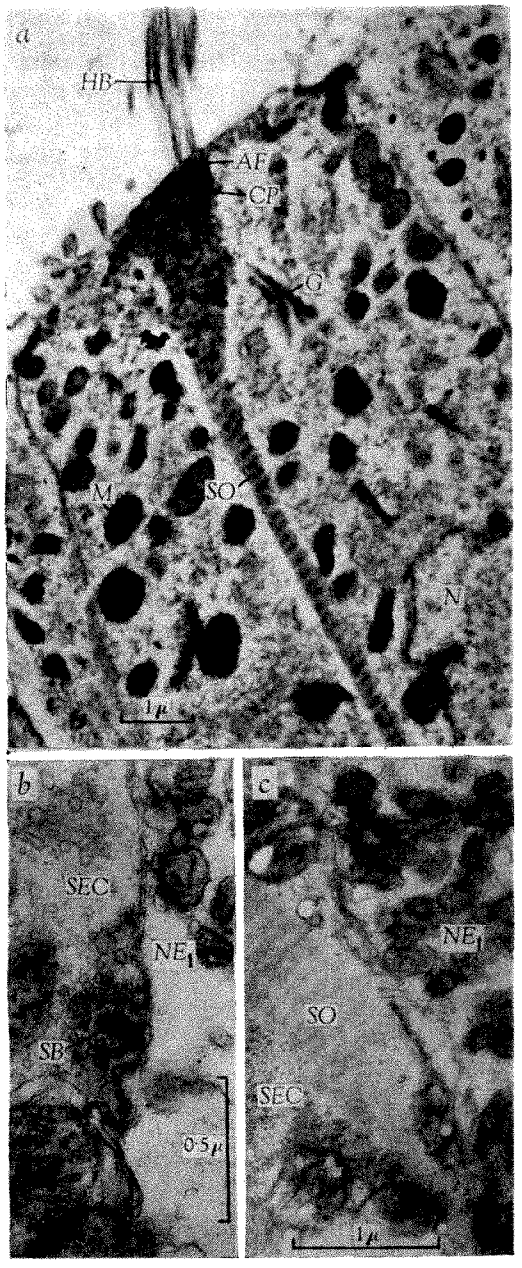

Fig. 2*a*. An electron micrograph of the apical region of a sensory cell showing the striated organelle continuing from the cuticular plate down past the level of the nucleus. *AF* = axial fibre; *CP* = cuticular plate; *G* = Golgi apparatus; *HB* = hair bundle; *M* = mitochondria; *N* = nucleus; *SO* = striated organelle. *b*, A micrograph showing the synaptic region at the base of a sensory cell. Note the electron dense synaptic bar surrounded by a cluster of vesicles. NE_1 = nerve ending; *SEC* = pre-synaptic cytoplasm of sensory cell; *SB* = synaptic bar. *c*, A micrograph of the synaptic region at the base of the sensory cell showing the striated organelle closely associated with the synaptic membrane. NE_1 = nerve ending; *SEC* = pre-synaptic cytoplasm of sensory cell; *SO* = striated organelle

lamprey. On the whole the ultrastructure of both the sensory cells and of the supporting cells conforms with the pattern described for the elasmobranch labyrinth. However, some new features were observed which appear to us worthy of early communication, before the report on the complete survey of the lamprey labyrinth is published elsewhere.

Fig. 1 shows a schematic representation of the sensory hair-cell. It appears to us of considerable interest that the cell contains typical synaptic bars surrounded by an accumulation of vesicles. The organelles appear to be identical to those described by Smith and Sjöstrand in the external hair-cells of the guinea-pig cochlea[2]. Figs. 1 and 2*b* show such synaptic bars (*SB*) in close association with nerve endings (NE_1). Similar bars have also been found in the sensory cells of electro-receptors in electric fishes[3]. These cells, too, belong to the acoustico-lateralis system.

A second feature of potential functional importance is an organelle, which runs from the cuticular plate at the top of the sensory cell, in which the roots of the stereo-cilia are anchored, down through the cytoplasm towards at least some of the synaptic structures at the base of the cell. The organelle is a cross-striated extension of the cuticular plate (Figs. 1 and 2*a*, *CP*). Its periodicity ranges from 120–190-μm with an average repeat of 130-μm. When seen in cross-section it appears to be composed of longitudinal fibrillæ. In passing down the cell the organelle divides either above or below the level of the nucleus. The nucleus is usually grooved along one side, forming a longitudinal invagination in which runs a branch of the striated organelle. Where the organelle approaches the base of the cell, it curves round and its striations thus continue to run perpendicular to the cell membrane, which it can approach very closely.

Essentially similar striated organelles have been described by Mountford in the light-sensitive cell of the rat retina[4]. They, too, are closely associated with the synaptic regions of the cell and also run in close proximity to the nucleus. No such organelle has, to our knowledge, as yet been described in the labyrinth of any other animal. Its functional significance is obscure, but it is tempting to suggest that its association both with the cuticular plate and with synaptic structures may mean that it is in some way concerned with the relaying of excitation caused by the mechanical deformation of the hair-bundle and the cuticular plate to the synapses and nerve endings at the base of the cell.

Tissue Cultures on Solid Media

When tissue cultures of mouse tumours were routinely tested for mycoplasma by inoculation in Petri dishes containing Difco PPLO agar (7 parts), 25 per cent yeast extract (1 part) and horse serum (2 parts), a nodule of tumour cells 2 mm in diameter was seen on the agar surface of one dish examined after 14 days at 37° C. Several cell lines were then inoculated into this medium with substitution of fœtal calf serum for horse serum and the addition of 100 μg/ml. each of penicillin and streptomycin.

Differences in the appearance of various cell lines were noted when these cultures were examined after cultivation in a sealed aluminium desiccator for 2 weeks. Established cell lines routinely maintained in Eagle's medium, 10 per cent fœtal calf serum and antibiotics, including fungizone (2·5 μg/ml.), were each trypsinized to fresh culture medium and sedimented at 500 r.p.m. in centrifuge tubes; the supernatant fluid was discarded and cellular sediment was distributed with a Pasteur pipette to the surface of 1 ml. of agar medium contained in a Leighton tube, so that cell groups approximately 1 mm in diameter were produced.

After incubation for 4–5 days, the appearance of the cell aggregate was distinctive. $P388D_1$ mouse lymphoma had relatively dense, monolayer cell clusters with irregular

borders. A variant of this cell line altered by chronic infection with polyoma virus (PV) for 11 months had irregularly rounded cell nodules with regular, fairly sharp borders. A second variant of $P388D_1$ chronically infected with PV for 1 year was essentially non-viable on this medium; only a few scattered cells survived. A spontaneous mouse mammary carcinoma known to contain mammary tumour virus (MTV) had relatively round nodules of cells with indistinct cytomembranes and had a peripheral, irregular fringe of attached cells. A mammary tumour induced in *BALB-c/Crlg* mice with MTV had irregular, monolayer clusters of loosely associated cells. This cell line infected with PV for 2 months had dense nodules of cells and an extensive peripheral, monolayer outgrowth of polyhedral cells. Hamster embryo tissue culture, which grew as sheets of epithelioid cells in fluid media on glass, had on agar media dense, irregularly shaped nodules with relatively sharply defined nodular borders; this strain infected (1 year previously) with PV had the same appearance. Mouse embryo fibroblasts had irregular, relatively loose clusters of cells in a monolayer with irregular border. This strain infected (1 year previously) with PV had tight nodules of varying size with irregular borders and composed of cells of uniform appearance. A second strain of the mouse embryo cells infected with PV for the same length of time was non-viable on agar.

Agar layers were removed from the tubes with the aid of a spatula; contact impression smears of the cells were made on glass slides and stained. Varying numbers of viable cells were found for the cell lines. Similar cultures were made using 'Colab', 3 per cent ionagar (3 parts), Eagle's solution (5 parts), fœtal calf serum (2 parts). The appearance of several cell lines after incubation for the same time-interval differed somewhat from that seen on 'PPLO' agar. These observations suggest that colonial morphology of murine and hamster cells may be characteristic for a given strain cultured on a given solid medium.

Participation of Cytochrome Oxidase in Lignification

INVESTIGATIONS during recent years on the more exact characterization of 'redoxases' involved in the lignification process have led, in the first instance, to the suggestion that this enzyme may be a laccase[1]. But since the distribution of laccase is principally restricted to lower plants, the consideration of laccase as the sole dehydrogenating enzyme in the formation of lignin cannot be accepted. Siegel[2,3] especially directed attention to another enzyme, namely, peroxidase. This enzyme can form lignin-like products from eugenol in the presence of hydrogen peroxide. Hence it is quite possible that also *in vivo* in the zone of lignification of a woody plant, peroxidase is an essential part of the mechanism of lignification. In fact, investigations of Wardrop and Bland[4] on the topological distribution of peroxidase by means of benzidine/hydrogen peroxide in the lignification zone have shown a positive reaction in the cambium cells and in the walls of the first dividing xylem cells, but as soon as a lignification did occur, peroxidase could no longer be detected.

This principle of reciprocal exclusion of lignin reaction and peroxidase activity seems to be universal, especially in structures of the wood[5] and the bark (bast fibres). Investigations here[6] have confirmed the results of the Australian workers. Furthermore, during this work we have found that the bulk of peroxidase is not localized within the cambium area or the differentiating xylem, but in the bark. Moreover, the peroxidase activity detected in the walls of young xylem cells disappears when lignification begins. The lignification of the middle lamella, however, is not the end, but the commencement of the lignification process; the formation of the secondary wall requires further quantities of lignin, which are produced likewise under the action of a redoxase. We were able to demonstrate that the enzyme necessary for this purpose is cytochrome oxidase (indophenol oxidase).

Cross-sections of shoots of 1-year-old *Pinus sylvestris*, *P. strobus*, *Abies alba*, *Acer platanoides*, *Populus nigra*, and *Aesculus hippocastanum* were investigated during the growth period in the second year (March–June). Since cytochrome oxidase is an extremely sensitive enzyme, any fixation and embedding procedures are out of the question; furthermore, one cannot obtain a certain thickness of sections without serious damage to the cell structure and therefore the activity of enzyme. On the other hand, a diffusion of the enzyme is scarcely to be expected, since it is closely bound to cell structures (mitochondria). Hence, we have worked with fresh slices, occasionally also with fresh frozen sections (cold-knife sections). For the histochemical detection of cytochrome oxidase we have utilized the *G*-Nadi reaction according to Moog[7] (0·01 M dimethyl-*p*-phenylene diamine + α-naphthol, *p*H 5·8; post-treatment with potassium acetate).

Both deciduous and coniferous woody species give approximately the same results. In each case, the walls of bark and cambium cells show no activity. The plasm of cambium cells is, if at all, only very weakly coloured. In this case, however, when the middle lamella of the differentiating xylem begins to lignify (detected by the phloroglucinol/hydrochloric acid reaction), a deep violet coloration appears within the cell wall after treatment with the Nadi-reagent. The reaction is so strictly located that with post-treatment of the same section with phloroglucinol/hydrochloric acid only those cell wall parts react which also contain the enzyme. Simultaneously with the lignification of the secondary wall the enzyme appears instantly; the coloured area increases with the thickening of the secondary wall. As soon as the wall

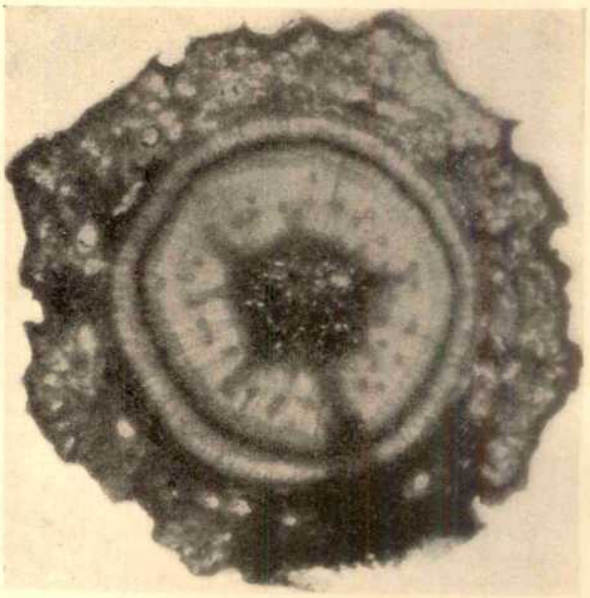

Fig. 1

has reached its full development, the activity disappears from the middle-wall layers, and a short time afterwards also the entire wall is free of enzyme.

According to conditions of growth and species of plant the number of cell series showing in their walls an enzyme activity differs. In each case, the walls of xylem cells, which are formed first and the lignification of which is complete, are already free of any enzyme activity. Fig. 1 shows a cross-section through *Pinus sylvestris*, in which the unbroken circle of indophenol blue in the differentiating xylem can be recognized. The same situation can be observed in the differentiating bast fibres of the bark, which lignify likewise, at least partially. During a certain development stage also here appears an important activity of cytochrome oxidase, which conforms with the lignification process. Tests on woody shoots many years old have shown the same results as such shoots one year old: cytochrome oxidase is found only in the differentiation region of the xylem; all older wood regions react negatively.

From the results of the investigation recorded here, we suggest that the principal redoxase involved in the lignification process of cell walls of higher plants is cytochrome oxidase. In order to establish the place on which the proton of the phenolic hydroxyl entered in the oxido-reduction chain of the succinic oxidase system, further investigations are necessary; presumably cytochrome c is primarily reduced.

Piricauda Bubak from India

Bubak (1914) recognized *Stigmella* Lev. as a pycnidiaceous, phæophragmosporous fungus and so erected the genus *Piricauda* to accommodate *S. uleana* Sacc., a simple dematiaceous and phæodictyosporous member. Moore[1], working on 'sensu Saccardo', where many forms producing phæophragmo and dictyospores were immixed with simple dematiaceous, pycnidial, sporodochial and acervular forms, separated genera like *Cheiromyces* Berk and Curt., *Dictyosporium* Corda., *Sporidesmium* Link. ex Fr., *Steganosporium* Corda., *Berkleasmium* Zoebel., *Stemphylium* Wallr., and *Piricauda* Bubak, with monacrogenous conidia. Moore's[2] monograph on the genus *Piricauda*, in which 38 species were considered, further establishes and clarifies this.

The genus *Piricauda* is characterized by producing micronemic, dematiaceous colonies, consisting of continuous or separate, simple conidiophores arising from the creeping hyphæ, cutting off phæodictyospores monacrogenously. The conidiophores are sometimes reduced to a single cell or a peg-like structure or entirely absent. During an investigation of Hyphomycetes of Hyderabad a species of *Piricauda* was collected by us and described as new, *Piricauda obclavata*, since it differed from the known ones. This is not only the first record of this fungus from India but also an addition to the known species.

Piricauda obclavata sp. nov. This fungus produces black, pin-head-sized colonies on the substratum. Colonies are micronemic, cushion-shaped with dark brown, septate, sparingly-branched hyphæ. Hyphæ are characteristically

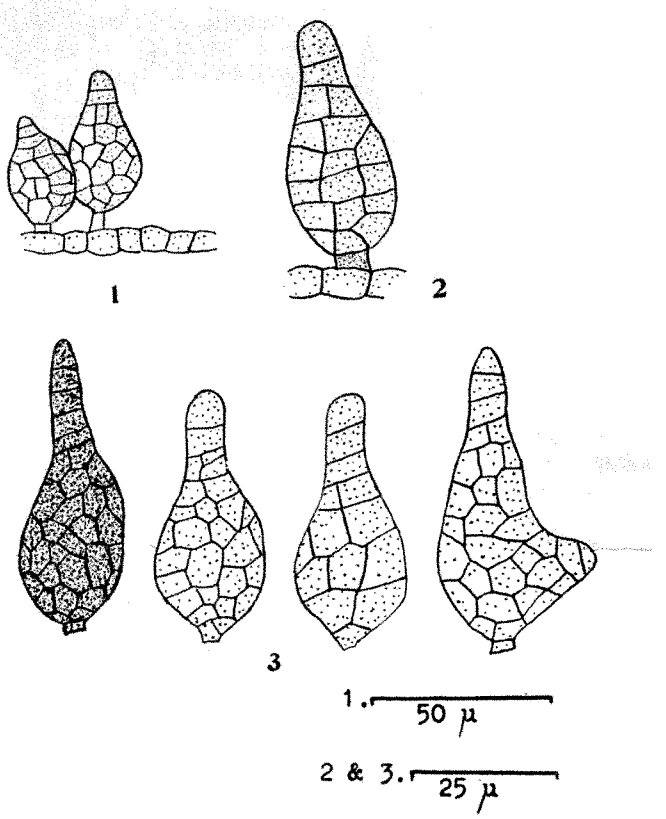

Fig. 1. 1, part of colony; 2, conidiophore and conidium; 3, conidia

attenuated at the septa, thick-walled, 3–7·2μ broad and the septa are 7·2–10·8μ apart. Conidiophores arise singly from the cells of the creeping hyphæ. The conidiophores arise continuous, yellowish-brown, very short, 3–7μ long, 1·5–3·6μ broad, producing conidia monacrogenously. Conidia are dictyosporous, black to blackish brown, opaque when mature, obclavate, 32–47μ long, 14–22μ broad at its widest, with a short or slightly elongate apical beak, 13–35 celled. Rarely are conidia observed with a lateral beak also.

We thank Prof. M. R. Suxena, Department of Botany, Osmania University, and Dr. S. D. Satwalekar, principal, Vivek Vardhini College, Hyderabad, for facilities and advice.

Full diagnosis of *Piricauda obclavata* can be obtained from the author.

MICROBIOLOGY

Sub-microscopic Structure of Injured Surface of *Paramecium caudatum*

Paramecium caudatum is a very suitable object for observing the regeneration of the surface of Protozoa. The cell surface of *Paramecium caudatum* is composed of pellicula and cilia which are distributed evenly all over the cell surface.

The defect in pellicula of *Paramecium* was made in such a way that the front or back part (about 0·25 of the cell) was removed. The nuclear fragments were fixed with buffered 1 per cent osmium tetroxide (*p*H 7·2) for

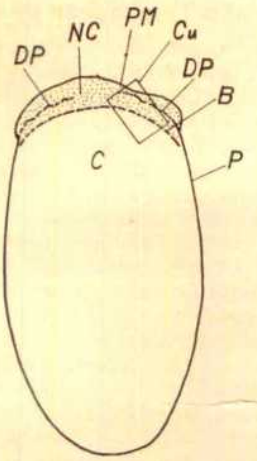

Fig. 1. Diagram of defect in surface of *Paramecium caudatum* 15–30 min after cutting. *P*, Pellicula; *DP*, partly damaged pellicula; *PM*, precipitation membrane; *C*, normal healthy cytoplasm; *NC*, necrotic cytoplasm; *B*, boundary between necrotic cytoplasm and normal cytoplasm; *Cu*, cutting presented in Fig. 2

10 min at different times (1, 2, 5, 7, 15, 30, 60 min, 2, 8, 24 h) after cutting. The fixed fragments were dehydrated and embedded in methacrylate mixture in such a way as to enable us to attain serial ultra-thin sections upright to the regenerating surface. Ultra-thin sections were cut on a Niklowitz ultramicrotome and examined with Tesla *BS* 242 electron microscope. The results were obtained by examining serial ultra-thin sections.

In cross ultra-thin sections (2–5 min after cutting) we can observe the partly damaged pellicula surrounding the wound of the injured end of the fragment. This partly damaged pellicula does not include cilia; but the kinetosomes are present. Towards the centre of the wound only a few remnants of pellicula remained. A small amount of necrotic cytoplasm which poured out when cutting the cell continues to be connected with the wound. The necrotic cytoplasm is coarsely and uniformly granulated and it does not contain any organelles (mitochondria, trichocysts, vacuoles, endoplasmic reticulum) which are present in normal cytoplasm. The surface of the necrotic cytoplasm is covered with a membrane; it is probably the surface precipitation membrane which seems to be connected with the membrana interna pelliculæ. The partly damaged pellicula extends, as a rule, under the remnants of extended necrotic cytoplasm. A small amount of necrotic cytoplasm occurs under the partly injured pellicula, also. After a short period following the cutting (5 min) the transition between the necrotic and the healthy cytoplasm is gradual without any boundary. In sections of fragments regenerating 15–30 min, a distinct boundary between necrotic and healthy cytoplasm is to be seen (Figs. 1 and 2). The boundary is formed by a layer of very fine granulated osmiophilic material, the thickness of which is 300–500 mμ. With the fragments regenerating for 24 h the unbounded pellicula is decreased in size. This decrease is probably brought about by the shifting of the remaining healthy pellicula. The membrane covering the remainder of the defect in pellicula is smooth without a complicated structure of normal surface. The value and further destiny of this boundary are so far unknown.

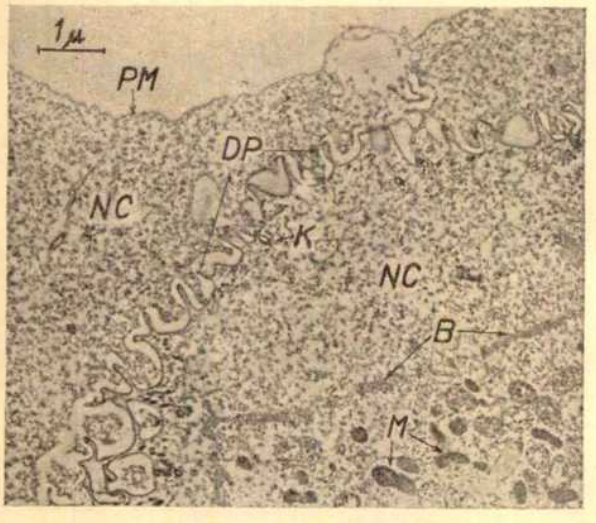

Fig. 2. Ultra-thin section through regenerating surface of fragment of *Paramecium caudatum* 15–30 min after cutting. *K*, Kinetosome; *M*, mitochondria (× *c.* 8,660)

There are also numerous changes in the organelles of the regenerating fragment. The mitochondria in the vicinity of the wound are swollen. The macronucleus of the regenerating fragment is more lobular in comparison with the macronucleus of the normal *Paramecium*. We cannot as yet determine whether all these observed changes are secondary results of changed physical and chemical conditions after cutting, or whether it is an active physiological reaction, which is directly connected with the processes of regeneration.

A Culture Medium proposed for the Isolation of *Streptococcus faecalis, sensu strictu*

Recently, a medium has been proposed[1] for the specific detection of *Streptococcus faecalis, sensu strictu*, with the implication that this micro-organism resides almost exclusively in the intestinal tract of man. The functional ingredients of the medium depend on the ability of *S. faecalis, sensu strictu*, to ferment sorbitol, utilize tyrosine, and reduce 2,3,5-triphenyltetrazolium chloride (TTC) when incubated in agar at 45° C after a preliminary incubation at 37° C.

Unless one has rather an intimate knowledge of the source of the pollution, the implication that recovery of typical colonies indicates pollution only of human origin appears untenable in the light of recent investigations. The typical *S. faecalis* is not, as has been commonly assumed, a resident exclusively of the human intestinal tract. In all probability the concept came into being during the earlier years of bacteriology when the complexities of the genus *Streptococcus* were appreciated, and when workers concerned with *S. faecalis* were oriented strongly toward medical bacteriology. It and *S. liquefaciens*, which must be considered together with *S. faecalis*, are widespread among truly wild animals in an environment remote from the influence of man[2], and on plants in both truly wild[3] and agricultural environments[4]. Natural populations of several hundred thousand per gram of selected plant material have been noted, and ability of the bacteria to grow with the plant from inoculated seeds has been demonstrated[5]. The bacteria are not uncommon in the intestinal tracts of hogs[6], domesticated mink[7], calves[8], and sheep[9]. Kjellander[10] has also recovered these bacteria from farm animals.

One may question the characteristic described for the medium with ability to select only *S. faecalis, sensu strictu*. Except for the proteolytic enzyme, *S. liquefaciens*, whether isolated from human beings, plants, or animals, is indistinguishable from the non-proteolytic, non-hæmolytic *S. faecalis*. 255 strains isolated from all sources in our laboratory initiated growth vigorously in broth at 45° C

without prior incubation at 37° C, all reduced TTC to produce maroon-coloured colonies, and only 7 cultures failed to ferment manitol. Distinction between strains or species with respect to utilization of tyrosine was not pursued when it was noted that 10 of 47 cultures of the strongly reducing group of enterococci isolated from plants failed to utilize it, and the remaining 37 cultures utilized it in varying degree from slightly to extensively. On Mead's medium, strains of *S. liquefaciens* respond in a fashion identical with that of *S. faecalis, sensu strictu*.

Table 1. Growth and Utilization of Tyrosine on Mead's Agar by Selected Strains of *Enterococci*

Species, source and strain	Ratio of growth, Mead's medium/*MRS*	Clearing around colony	Clearing on streak plates
Human			
H 33 *a S. faecalis*	2·6	Good	Good
H 41 *a S. faecalis*	0·17	Detectable	Good
H 46 *a S. faecalis*	No colonies	—	Good
Animal			
R 76 *b S. liquefaciens*	0·04	Good	Good
R 100 *c S. liquefaciens*	0·16	Good	Good
R 107 *b S. liquefacients*	1·1	Poor unless colonies concentrated	Good
R 26 *a S. faecalis*	No colonies	—	Slight
Plant			
a 70 *S. faecalis*	1·0	Good	Good
137 *a S. liquefaciens*	0·9	None	*
140 *bl S. liquefaciens*	0·01	Poor	*

* No observation.

Other points at issue involve the quantitative aspects of recovery, and the inability of selected strains to produce typical colonies on Mead's medium. From our stocks, 10 cultures, 5 each of *S. faecalis* and *S. liquefaciens* including 3 obtained from human stools, 4 from wild animals, and 3 from plants, were selected at random. After overnight incubation in broth, the cultures were plated serially at 1×10^{-7} and upwards in parallel on the medium of De Man, Rogosa and Sharp (*MRS* medium)[11] and on Mead's medium.

Counts of colonies on *MRS* medium ranged from $1{\cdot}9 \times 10^{7}$ to $6{\cdot}8 \times 10^{8}$. Three cultures, one from each source, produced numbers of colonies equal to the number produced on *MRS* medium, as shown by the ratio Mead's medium/*MRS* in Table 1. Two cultures, one human and one animal in origin, failed to produce colonies at the lowest dilution plated, while the numbers of colonies of the remaining 5 cultures were 1–17 per cent of those on *MRS* medium. The colonies of all cultures which grew were maroon in colour; however, 4 cultures decomposed tyrosine well, as indicated by clear zones around the colonies, 1 culture with a high plate-count ratio produced no clearing, while 4 cultures decomposed tyrosine so slightly that in routine work the clearing would be undetectable. When streaked on Mead's medium, 7 of 8 cultures developed excellent clearing, especially where colonies were concentrated.

From these observations one must conclude that the Mead's medium is not selective for the detection of *S. faecalis, sensu strictu*; that colonies appearing on the plates of the medium could come from sources other than human, and that enterococci originating from the human may neither be detected nor produce typical colonies.

Action of D-Tryptophan on *E. coli*

DL-Amino-acids as substitutes for L isomers are often used in culture media of the microbial organisms and mammalian cells. The common absence of growth inhibition by using DL-amino-acids in the culture media led to the notion that D isomers are nutritionally inert. While this remains generally true in the sense of the culture of wild-type strain of micro-organisms, it is now apparent in our report that D-amino-acid even in the low concentration of 10^{-5} M inhibits the growth of the L-isomer-requiring mutant. Although several D-amino-acids have been found to inhibit cell division and growth[1–3], the effect of D-tryptophan for cell growth has never been reported except that the high concentration of DL-tryptophan ($6{\cdot}8 \times 10^{-3}$ M) caused formation of extremely long cells of *Erwinia* after 16 h incubation and that higher levels of the D-amino-acid resulted in growth inhibition[1]. This paper presents evidence that D-tryptophan in low concentration (10^{-5} M) was found to inhibit the growth of an L-tryptophan-requiring mutant of the *E. coli*, and the inhibition of the active transport is one of the bases of the growth inhibitory action of D-tryptophan on *E. coli*.

The mutant of *E. coli K*-12 (Yale) used in this report is the tryptophan auxotroph, *B*-8, which forms normal *A* component and trace amount of extremely labile *B* component of tryptophan synthetase[4]. Bacteria were grown in 5–10 ml. of the minimal medium supplemented with 0·2 per cent of glucose and 5 μg of L-tryptophan per ml.[5]. D-Tryptophan (2·5–20 μg per ml.) added to the medium inhibited cell growth of *B*-8 strain (Table 1).

Table 1. Growth Inhibition of *B*-8 Cells by D-Tryptophan

Incubation (h)	Addition of D-tryptophan μg/ml. 0	2·5	5·0	10·0	20·0
	Klett unit*				
9	115	74	72	64	64
12	205	123	115	86	73
15	220	173	162	113	89

Cells were grown for 9–15 h in the minimal medium supplemented with 5 μg of L-tryptophan/ml. in the presence of D-tryptophan with shaking at 37°
* The turbidity was measured with a Klett–Summerson colorimeter with filter 54 and was expressed as Klett unit.

The time course of growth of *B*-8 which was markedly inhibited in the presence of D-tryptophan is shown in Fig. 1.

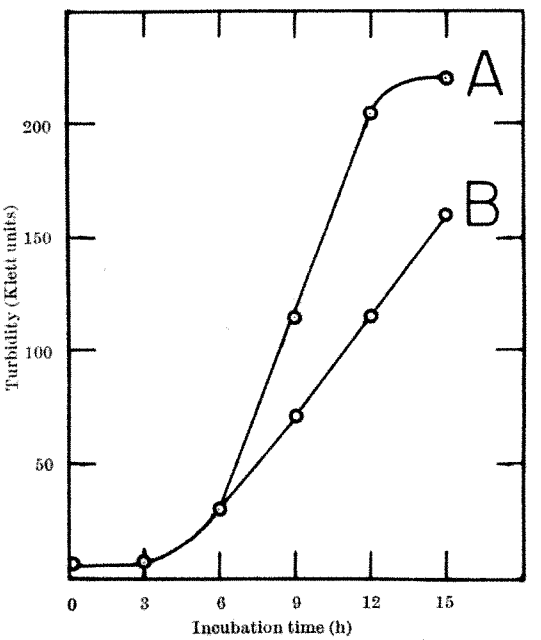

Fig. 1. Growth curve of *B*-8 cells in the presence or absence of D-tryptophan. The experimental details are the same as those described in Table 1. Curve *A* shows the growth of *B*-8 cells in the absence of D-tryptophan and curve *B* shows the one in the presence of 5 μg of D-tryptophan per ml. Both contain 5 μg of L-tryptophan/ml. and 0·2 per cent of glucose on the minimal medium

Table 2. EFFECT OF D-TRYPTOPHAN ON RADIOACTIVE AMINO-ACID UPTAKE

Radio-active amino-acid*	Control c.p.m.	D-Tryptophan (50 μg/ml.) c.p.m.
L-tryptophan-^{14}C	321	180
L-proline-^{14}C	1,094	1,080
L-valine-^{14}C	1,185	1,053

The reaction mixture contained per ml.: 50 μg of dry weight of cells; 40 μg of chloramphenicol; 17 μmoles $MgCl_2$; 10 μmoles sodium formate; 10 μg L-amino-acid-^{14}C (10^4 c.p.m./μg); 25 μmoles *tris*; final *p*H 8·0[7]. After incubation for 1 min at 35° each reaction mixture was filtered on 'Millipore' filter *HA*. The filter was washed with 10 ml. of 0·9 per cent sodium chloride, dried and counted[7].

*All amino-acids; L-tryptophan, benzene ring uniformly labelled, prepared enzymatically[6]; L-proline, uniformly labelled; L-valine uniformly labelled; were adjusted to 10,000 c.p.m./μg with addition of carrier ^{12}C-amino-acid.

Even at the highest level employed (100 μg/ml.) growth of the *B*-8 cells was not completely inhibited by D-tryptophan. Morphologically, no shortening or elongation of the cells was observed in the concentration range of D-tryptophan (2·5–100 μg/ml.). The fact that *B*-8, a tryptophan auxotroph, is unable to grow in a minimal medium containing D-tryptophan (5–100 μg/ml.) indicates that D-tryptophan cannot substitute L-tryptophan for the growth of the auxotroph. The possibility was examined that D-tryptophan may inhibit bacterial growth by interfering with the uptake of L-tryptophan. To determine the effect of D-tryptophan on the uptake of L-tryptophan by the cells, washed bacteria were incubated in the minimal medium containing ^{14}C-L-tryptophan at 35°. In the presence of D-tryptophan uptake of radioactivity into the cells was significantly reduced (Table 2). Uptake of L-proline-^{14}C or L-valine-^{14}C was little affected in the presence of D-tryptophan. In the intracellular site, activation of L-tryptophan (L-tryptophanyl–adenosine monophosphate) and synthesis of L-tryptophanyl–RNA, which participate on protein synthesis, were not influenced in the presence of D-tryptophan[6].

A tryptophan transport system in *E. coli* reported by Boesi and DeMoss[7] and our findings that D-tryptophan inhibited uptake of L-tryptophan into a tryptophan auxotroph of *E. coli* suggest that a mechanism of the growth inhibition of a tryptophan-auxotroph, B-8, by D-tryptophan is the disturbance of L-tryptophan transport into the cells.

Transformation of *Leptospira*

THE well-known pioneer experiments of Griffith[1], in 1928, proved the phenomenon of transformation in the *Pneumococcus*; the genetic characteristic transmitted was the virulence, of which the elaboration of the capsule is the phenotypic expression. Avery, MacLeod and MacCarthy[2] elucidated the cause: the genetic material, freed in solution, is sensitive to deoxyribonuclease; it is thus DNA. This pattern of 'transfer' has since been observed in other bacteria.

From our investigation on recombinations through transformation in *Leptospira* we used a strain of *Leptospira icterohaemorrhagiae* isolated in 1958 from a rat (*Rattus norvegicus*) captured in a coal-mine; the strain was named 'Cheratte' after its place of origin in the region of Liège. Cultivated in our laboratory, it has, as usual, quickly lost its pathogenic power.

Starting in February 1963 from the twelfth sub-culture, we succeeded through serial passages on guinea-pigs in restoring its virulence: it kills the animal within 6–8 days, showing the usual ictero-hæmorrhagic picture. The mixture of 1 ml. of virulent culture disrupted by successive freezing and thawing and 1 ml. of an initially non-virulent living culture has twice, in May 1963 and July 1964, caused the death of the guinea-pig together with icterus, numerous hæmorrhages and the presence in the organs of leptospires which can be re-inoculated in series. All these experiments were conducted with the necessary control experiments.

Besides this homotransformation, we succeeded in heterotransformation. The transfer principle came from the 'Cheratte' strain made virulent; the receiving microorganism was the 'Kantorowicz' strain, belonging to the serotype of group *Icterohaemorrhagiae*, for a long time designated as *A* or incomplete. This strain, isolated in 1931 at Amsterdam from the blood of a patient, lost its pathogenic power many years ago.

During the same experiment which allowed us, in July 1964, to succeed for the second time in our homotransformation, 1 ml. of the live culture of 'Kantorowicz', mixed with the same quantity of the killed culture of virulent 'Cheratte', resulted in the death of the guinea-pig on the eleventh day, with hæmorrhagic icterus. The 'Kantorowicz' strain thus made virulent remained so during several passages.

This work was supported by a research grant of the Fonds National de la Recherche Scientifique, Belgium.

CYTOLOGY

Distribution of Phthalocyanine Dye (Heliogen Blue *SBL*) in Ultrastructures of Vital Dyed Axons of the Crab *Carcinus maenas*

VITAL molecular disperse dyes are widely used in the investigation of permeability mechanisms and structural chemical changes in the cell[1]. The possibility of revealing such substances by means of the electron microscope was suggested by Isenberg[2] and later confirmed experimentally on preparations stained after the fixation[3,4]. Using an electron microscope Barrnett[5] revealed the azodye vitally formed in the cell as a result of a certain histochemical reaction.

The distribution of the acid substantive dye, heliogen blue *SBL* (HB) containing one copper atom, has been investigated with the aid of the electron microscope in vital-dyed axons of the crab, *Carcinus maenas*[6,7]. HB as observed on the film or in ultra-thin sections is characterized by a high electron density.

Axons were stained with 2 per cent HB solution diluted in artificial sea water without bivalent cations at *p*H 6·8 (phosphate buffer) for 2 h at 18°–20° C. Under such conditions diffusion equilibrium between the axon and the dye solution was reached in 1 h. The action potential of the axons in 2 per cent HB solution persisted for 3 days. Quantitative measurements of HB in crab's nerves prove that a half of the dye was dissolved or weakly bound, whereas the remaining portion was bound more strongly (Table 1).

For the electron-microscope investigation the stained and unstained axons were fixed in 2 per cent isotonic

Fig. 1. Part of cross-section of two adjacent axons of the crab. Unstained axons were fixed in OsO_4 (×35,000)

Fig. 2. Part of cross-section of axon stained in 2 per cent HB. Membranes of the sheath are characterized by increased electron density. The arrows indicate HB accumulations in axolemma (*ax*). Collagen fibres (*c*) show increased electron density (×30,000)

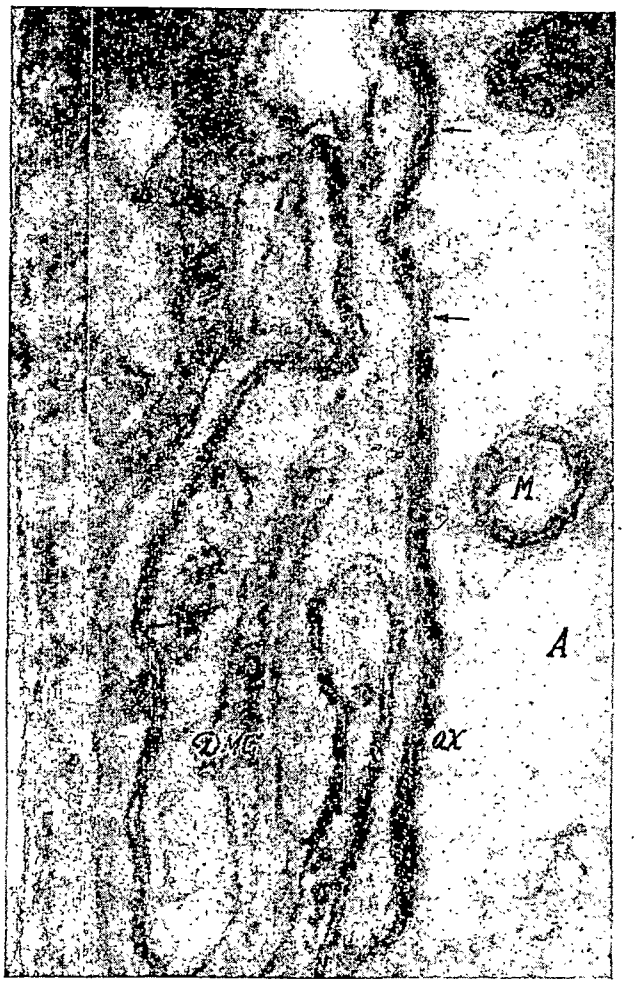

Fig. 3. Part of cross-section of axon stained in 2 per cent HB. As in Fig. 2 one can observe an increase in electron optical contrast of membrane structures of the axon sheath. The dye is localized in axolemma (*ax*) chiefly as discrete granules. Some mitochondrial membranes (*M*) in axoplasm (*A*) have increased electron density. Local dilation of mesaxon gap (*DMG*). The arrows indicate sites with triple-layered structure of axolemma. Some parts of the middle layer of axolemma exhibit increased electron density (×100,000)

solution of osmium tetroxide buffered with veronal buffer at *p*H 6·8, then dehydrated in ethanol and embedded in 'Araldite'. The analysis of ultra-thin sections of the stained axons has shown that HB is revealed in the membrane structures of fibre sheaths. The dye causes the latter to stand out in contrast as compared with the control object (Figs. 1 and 2). In some cases areas of increased electron density were found in axoplasm on mitochondrial membranes (Fig. 3). Moreover, HB is intensely bound in collagen fibres (Fig. 2).

The dye has a negatively-charged chromophore group and is not soluble in hydrophobic solvents. It would be only natural to suggest that the dye is bound by protein components of the membrane and not by phospholipides. This is in agreement with the facts of the acid dye binding by proteins[8]. In the region of axolemma wherein its triple-layered character is evident the dye is localized in external and probably protein layers (Fig. 3). This fact seems to be an indirect confirmation of our suggestion.

In some areas of axolemma there are accumulations of HB in the shape of granules which fill up the whole

Table 1. Amount of HB in the Nerves of the Crab's Leg when Stained with 2 per cent HB

Extracting fluid	HB concentration as percentage of net weight
Artificial sea water (*p*H 6·8)	3·2 ± 0·03
70 per cent C_2H_5OH (*p*H 12·8)	1·51 ± 0·1
2 M NaOH	1·63 ± 0·17

axolemma and vary in size from 50 Å to 400 Å (Fig. 3). These accumulations of the dye were observed only in some regions of axolemma. Such uneven distribution of the dye indicates structural heterogeneity of axolemma, unlike other cytoplasmic membranes. All the mesaxones in the investigated giant axones exhibit a winding character, their length varying from 4μ to 10μ. The width of gaps in mesaxons and axon-swann membranes is about 100–150 Å (Fig. 3). Sometimes in stained axons one sees mesaxon gaps widened to 500 Å or cavities with the maximal size about 0·7μ (Fig. 3). It is most probable that HB reaches axolemma through the mesaxon and axon-swann membrane gaps. This suggestion is based on the fact that the time of diffusion through a 150 Å gap (10μ long) is 10 times less than that required for attaining diffusion equilibrium between axons and the media. The absence of accumulations of electron dense dye in mesaxon gaps may be due to the washing out of the dye during fixation and dehydration of the object. Another possible way for the dye to reach axolemma is through plasmic membranes of the swann cell. However, no evidence was found to indicate the penetration of HB through these membranes.

Electron-dense granules in axolemma sometimes exceed the bounds of the latter and penetrate axoplasm (Fig. 3). It is possible that these regions of axolemma can be regarded as sites for HB influx in axoplasm.

VIROLOGY

Resistance of Synthesis of Influenza Virus Ribonucleic Acid to the Action of Actinomycin *D*

It has been found that replication of some myxoviruses (Sendai and NDV) was stimulated by actinomycin *D* (refs. 1 and 2) but in influenza and fowl plague viruses multiplication was inhibited by this antibiotic[3–5]. Based on actinomycin-induced inhibition of influenza hæmagglutinin production, Barry *et al.*[3] concluded that influenza virus RNA synthesis, unlike NDV, requires participation of cell DNA.

To decide whether actinomycin *D* prevents influenza and fowl plague RNA synthesis rate of ^{14}C-cytidine incorporation into strips of chorioallantoic membranes (CAM) and chicken fibroblasts was determined and autoradiographic investigation was carried out.

Four replicate strips cut from 11-day-old chick embryos and infected with a saturating dose of *PR*8 and Weybridge strain of fowl plague virus were used for each concentration of actinomycin (2, 4 and 8 μg/ml.). Chicken fibroblasts grown for 3 days in Hanks's salt solution containing 0·5 per cent lactalbumin hydrolysate and 2 per cent calf serum were infected with 10 ID_{50} p.c. of fowl plague virus; 0·3 μg/ml. of actinomycin *D* was used. Labelling was carried out with 2 μc./ml. of ^{14}C-cytidine added every 2 h to strips containing Hanks's solution and every hour to chicken fibroblasts. Strips and trypsinized cells were washed twice with cold phosphate-buffered solution, twice with cold 5 per cent trichloroacetic acid and twice with 96 per cent alcohol and once with ether. The results of three identical experiments (*A*) and a typical experiment (*B*) expressed as percentage of controls are shown in Fig. 1.

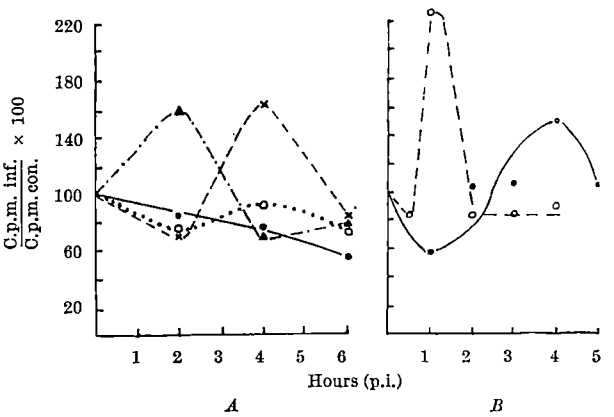

Fig. 1. Rate of ^{14}C-cytidine incorporation into *PR*8 virus infected CAM strips (*A*) and fowl plague infected chicken fibroblasts (*B*). ●, Cells without actinomycin *D*; ○, CAM strips treated with 2 μg/ml. of actinomycin *D*; ×, CAM strips treated with 4 μg/ml. of actinomycin *D*; △, CAM strips treated with 8 μg/ml. of actinomycin *D*; ○, cells treated with 0·3 μg/ml. of actinomycin *D*

In autoradiographic experiments *HEp*-2 cells were infected with a saturating dose of *PR*8 virus; 0·5 μg/ml. of actinomycin *D* was added just after infection. Every hour after onset of incubation samples of cultures were exposed to 1 μc./ml. of tritiated uridine for 30 min, washed with unlabelled uridine and fixed. The autoradiographic technique used has already been described[6].

All incorporated radioactivity in the control cells was localized in the cell nuclei with heavy labelling of nucleoli. Actinomycin *D* completely inhibited incorporation of tritiated uridine into nuclei of uninfected cells at all times of observation. No differences were observed in grain localization between control cells and infected cells for the first 2 h after infection. 3 h after infection, and later, labelling of nucleoli was inhibited (Table 1 and Fig. 2). Thus redistribution of grains was the only indication of *PR*8 virus infection; decrease in number of grains was in accordance with radioactivity measured (Fig. 1*A*).

Table 1. Incorporation of Tritiated Uridine into *HEp*-2 Cells Infected with *PR*8 Virus (Middle Number of Grains p.c.)

Intervals after infection (h)	Experimental: Control cells *N*	Control cells *n*	Actinomycin *N*	Actinomycin *n*	Infected cells *N*	Infected cells *n*	Actinomycin-treated infected cells *N*	Actinomycin-treated infected cells *n*
1	42±2·2	26±1·7	0	0	46±2·8	22±1·6	0	0
2	55±6·7	36±6·0	0	0	50±2·8	28±2·0	0	0
3	37±2·1	18±0·6	0	0	30±2·3	6±0·9	22±2·6	0
4	—	—	0	0	35±2·6	9±1·0	27±2·6	0
5	53±6·2	33±3·2	0	0	50±3·5	4±0·3	0	0

N, nucleus excluding nucleolus; *n*, nucleolus

There was no labelling of nuclei the first hour after infection of actinomycin-treated cells ; 2 h after infection single cells with labelled nuclei were seen ; 3 and 4 h after infection labelling of nuclei in most actinomycin-treated cells was observed. Grains were distributed over the whole nuclear area without any concentration in nucleoli (Fig. 2). Incorporation was absent at 5 h.

It may be concluded that actinomycin *D* does not prevent the synthesis of RNA of *PR*8 and fowl plague viruses, and, moreover, RNA synthesis starts earlier as well as with Sendai virus[1]. The replication of myxovirus RNA seems to proceed independently of cell DNA function. The inhibition of *HA* and *CF* antigen production of influenza and fowl plague viruses was observed when chicken fibroblasts were treated with actinomycin *D* no later than 2 h after infection and strips of chorioallantoic membranes no later than 3 h. In spite of 10–100 fold decrease in *HA* titre in actinomycin-treated

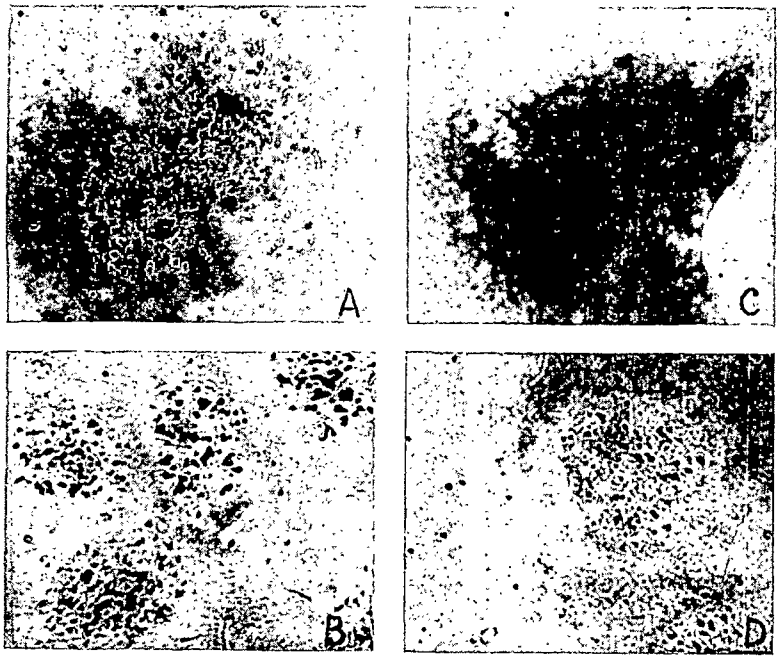

Fig. 2. *HEp*-2 cells: autoradiographs. Unstained (× 100). *A*, control cells; *B*, 3 h after *PR*8 virus infection; *C*, 1 h after actinomycin action, typical 'rosette' around nucleoli; *D*, actinomycin-treated cells 3 h after infection

chicken fibroblasts and chorioallantoic membrane strips, EID_{50} of *PR*8 virus as well as influenza viruses *A*/Asia/59, *B*/*Lih*/59 and *B*/95/61 was the same as in control cells. EID_{50} of fowl plague virus was lowered in accordance with *HA* and *CF* antigen inhibition.

Thus actinomycin *D* seems to interfere with a cystron of a new synthesized viral RNA molecule which is responsible for viral proteins production; other explanations are not excluded.

VETERINARY SCIENCE

Levels of Coenzyme *A* in the Liver of Normal Cows and of Cows suffering from Primary Ketosis

Highly significant changes have been shown in the levels of four members of the citric acid cycle (pyruvate, citrate, α-oxoglutarate and succinate) in the serum of cows suffering from primary ketosis[1]. It was suggested that there may be interference with the reactions of the citric acid cycle, involving the conversion of pyruvate and α-oxoglutarate to citrate and succinate respectively. Furthermore, it was suggested as a working hypothesis that the cause of such an interference may be a deficiency of a co-factor or co-factors common to both oxidative decarboxylation reactions, such as coenzyme *A*. During the winter of 1962–63 coenzyme *A* levels were estimated in the livers of 7 cows suffering from spontaneous primary ketosis and compared with the corresponding levels in the livers of 7 normal cows at the same stage of lactation.

Cores of liver tissue weighing 500–800 mg were removed by the biopsy technique described by Loosemore and Allcroft[2]. Immediately after removal, the liver core was placed on filter paper to remove surface moisture, then dropped into a test tube standing in a bath of acetone and solid carbon dioxide. Protein was estimated on 100 mg of the frozen tissue by the method of Lowry, Roseborough, Farr and Randall[3], while the rest of the liver core was transferred to a boiling tube containing 5 ml. water standing in a boiling water bath. The liver was boiled for 5 min, cooled, then homogenized in a Potter–Elvehjem homogenizer. The homogenate was made up to a known volume and centrifuged for 20 min at 20,000*g* in a Spinco model *L* ultracentrifuge. The coenzyme *A* content of the supernatant was estimated using a method based on the investigations of Stadtman, Novelli and Lipmann[4], who showed that coenzyme *A* catalyses the interchange of acetyl bound and inorganic phosphate, and the arsenolysis of acetyl phosphate by a phosphotransacetylase enzyme system. The procedure adopted has been described in detail by Reece[5].

It may be seen from Table 1 that there is a highly significant depression of the protein level of the ketosed liver. Therefore, although the level of coenzyme *A* (expressed as coenzyme *A*/g tissue) in the liver of the ketosed cow is lower than that found in the normal animal, no significant difference exists between the two groups when the coenzyme *A* concentration is expressed in terms of the protein content of the normal and ketosed tissue.

Table 1. Levels of Coenzyme *A* and Protein in the Liver of Normal Cows and of Cows suffering from Primary Ketosis

	Normal cases (7) mean ± *S.E.M.*	Pathological cases (7) mean ± *S.E.M.*	*P**
Coenzyme *A* : *LU*†/g tissue	94·6 ± 10·2	59·2 ± 14·8	0·1
Protein: mg/g tissue	185·0 ± 17·6	92·2 ± 8·5	0·001
Coenzyme *A*: *LU*†/100 mg protein	51·5 ± 5·2	62·0 ± 11·5	0·5

* Probabilities calculated by the *t* test (ref. 10).
† Lipmann units.
No. of liver samples estimated given in brackets.

In view of these findings in liver tissue, the hypothesis that the interference in the oxidative decarboxylation of pyruvate and α-oxoglutarate is due primarily to a deficiency of coenzyme *A* appears to be unlikely. It has been suggested[6,7] that this interference may be associated with other factors, such as deranged levels of the pyridine nucleotides, and other plausible arguments have been put forward[8]. However, it must be remembered that even in the normal cow there is a heavy drain on the coenzyme *A* reserves during the first 3 months of lactation due to the excretion of the co-factor in the milk[9].

Until the levels of all the co-factors relevant to oxidative decarboxylation can be thoroughly investigated in the tissues of the ketosed animal, it will be difficult to explain the accumulation of pyruvate and α-oxoglutarate in the blood of cattle suffering from a starvation or a spontaneous primary ketosis.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, October 12

INSTITUTION OF AGRICULTURAL ENGINEERS (at the Institution of Mechanical Engineers, 1 Birdcage Walk, London, S.W.1), at 10.15 a.m.—Mr. B. M. Camm: "Some Aspects of the Economic Utilization of Farm Machinery"; Mr. H. G. Pryor: "The Development and Application of High Power Units in Agriculture"; Mr. J. D. Savage: "Significant Features of Fuels and Lubricants for the Winter Use of Diesel-Engined Tractors".

INSTITUTION OF ELECTRICAL ENGINEERS, ELECTRONICS DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. E. N. Davies: "Application of Electronic Vector Scanning Techniques Applied to Height-Finding Landing Systems"; Miss E. Killick: "Frequency Scanning Aerial Systems".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. John Szentágothai (Medical University of Budapest): "The Neuronal Circuits of the Cerebellar Cortex".*

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 6 p.m.—"The Living Pattern" (Colour Films).

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (joint meeting with the Ewell County Technical College Faraday Society, at the Ewell County Technical College, Reigate Road, Ewell, Surrey), at 7 p.m.—Mr. A. D. S. Tantrum: "Energy Production".

Tuesday, October 13

INSTITUTION OF CIVIL ENGINEERS (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Mr. C. M. Johnson and Mr. J. J. Gandy: "Construction of the Maiduguri-Bama Road, Northern Nigeria".

INSTITUTION OF ELECTRICAL ENGINEERS, SCIENCE AND GENERAL DIVISION (at Savoy Place, London, W.C.2), at 5.30 p.m.—Prof. M. W. Humphrey Davies: "The Design and Control Revolution" (Chairman's Address).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.30 p.m.—Prof. R. King: "Metals". (Afternoon lectures for Sixth Form Boys and Girls from Schools in London and the Home Counties. Further lectures on October 14, 20 and 21.)

INSTITUTION OF MECHANICAL ENGINEERS, STEAM PLANT GROUP (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "Problems Involved in the Estimation of Steam Purity".

ROYAL AERONAUTICAL SOCIETY, ASTRONAUTICS AND GUIDED FLIGHT SECTION (at 4 Hamilton Place, London, W.1), at 6 p.m.—Monsieur R. Chevalier: "Some Aspects of Space Launcher Development Problems in France".

Tuesday, October 13—Wednesday, October 14

INSTITUTION OF MECHANICAL ENGINEERS (at the Royal Naval Engineering College, Manadon, Plymouth)—Conference on "Engineering in the Royal Navy".

Wednesday, October 14

SOCIETY OF ENVIRONMENTAL ENGINEERS (in the Mechanical Engineering Department, Imperial College of Science and Technology, London, S.W.7), at 6 p.m.—Mr. B. E. Grant: "Some Electronic Systems Applied to Environmental Problems".

INSTITUTE OF INFORMATION SCIENTISTS (at the Swedenborg Society Hall, 20 Bloomsbury Way, London, W.C.1), at 6.15 p.m.—Mr. H. F. Vessey: "Mechanization of Information Services in T.I.L., at the Ministry of Aviation".

INSTITUTION OF ENGINEERING INSPECTION (at the South-West Essex Technical College, Forest Road, Walthamstow, London, E.17), at 7.30 p.m.—Mr. J. Davey: "Testing Motor Cars for Quality and Reliability".

ROYAL AERONAUTICAL SOCIETY, GRADUATES' AND STUDENTS' SECTION (at 4 Hamilton Place, London, W.1), at 7.30 p.m.—Mr. B. S. Leete: "Commonwealth Air Routes Development".

Thursday, October 15

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. H. Grüneberg: "Genetical Research in an Area of High Natural Radioactivity in South India".*

INSTITUTION OF MINING AND METALLURGY (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—General Meeting.

INSTITUTION OF CIVIL ENGINEERS, JOINT BUILDING GROUP (at Great George Street, Westminster, London, S.W.1), at 5.30 p.m.—Informal Discussion on "Problems of Professional Collaboration in the Building Industry" introduced by Mr. W. A. Allen and Mr. C. E. P. Wooster.

CHEMICAL SOCIETY (in the Lecture Theatre, School of Pharmacy, 29–39 Brunswick Square, London, W.C.1), at 6 p.m.—Dr. A. D. Buckingham: "Experiments with Oriented Molecules" (Tilden Lecture).

ROYAL AERONAUTICAL SOCIETY (at 4 Hamilton Place, London, W.1), at 6 p.m.—Mr. J. T. Dyment: "Tools of Airline Management" (Twentieth British Commonwealth Lecture).

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS GROUP (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Dr. C. A. Chaplin: "The L.C.C. and Building Materials".

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. P. D. Marsden: "A Longitudinal Study of the Health of Gambian Children from Birth to the Age of Eighteen Months".

Friday, October 16

ASSOCIATION OF APPLIED BIOLOGISTS (in the Lecture Hall of the British Museum (Natural History), Cromwell Road, London, S.W.7), at 10.50 a.m.—Symposium on "The Problem of Persistent Insecticides in British Agriculture".

TELEVISION SOCIETY (at the Institution of Electrical Engineers, Savoy Place, London, W.C.2), at 7 p.m.—Mr. H. Steele: "Transcoding from SECAM to N.T.S.C.".

Saturday, October 17

LONDON COUNTY COUNCIL (at the Horniman Museum, London Road, Forest Hill, London, S.E.23), at 3.30 p.m.—Miss Alice G. C. Grandison. "Snakes, Lizards and Frogs of Nigeria".*

Monday, October 19

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Dr. J. L. Garraway: "Studies on Certain Organo-Sulphur Compounds as Fungicides".

ROYAL INSTITUTE OF CHEMISTRY, LONDON SECTION (at Enfield Technical College, Queensway, Ponders End, Enfield, Middlesex), at 7 p.m.—Dr. T. R. E. Kressman: "Ion Exchange".

ROYAL GEOGRAPHICAL SOCIETY (at 1 Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Eric E. Shipton, C.B.E.: "Over the North Patagonian Icecap".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

LECTURER/ASSISTANT LECTURER IN MATHEMATICS IN THE DEPARTMENT OF SCIENCE AND MATHEMATICS—The Principal, Rugby College of Engineering Technology, Eastlands, Rugby (October 14).

LECTURERS (3) (with good academic qualifications in physics, preferably including a higher degree) IN PHYSICS, for duties in the University Department of Surgery at the Royal Infirmary, Practice of Medicine at the Western Infirmary and Surgery at the Western Infirmary—The Secretary of University Court, The University, Glasgow (October 15).

ASSISTANT LECTURER (with a special interest in experimental psychology) IN PSYCHOLOGY—The Registrar, The University, Manchester, 13 (October 16).

PRINCIPAL LECTURERS (graduates with suitable teaching, research and/or industrial experience) at West Ham College of Technology, to teach the following subjects to degree students: civil engineering, mechanical engineering, electrical engineering, chemical engineering, organic chemistry and physics—Chief Education Officer, Education Department, 95 The Grove, Stratford, London, E.15 (October 19).

VICE-PRINCIPAL (with high academic qualifications, appropriate teaching experience at degree or diploma in technology level, and some administrative experience, preferably as Head of a Department) of West Ham College of Technology—Chief Education Officer, Education Department, 95 The Grove, Stratford, London, E.15 (October 19).

LIBRARIAN and an ASSISTANT LIBRARIAN (Fellows of the Library Association) at the University College of Science Education, Cape Coast, Ghana—The Assistant Registrar (Overseas), University College of Science Education, 15 Gordon Square, London, W.C.1 (October 20).

SENIOR LECTURER or LECTURER IN VETERINARY SURGERY—The Secretary of University Court, The University, Glasgow (October 25).

SENIOR LECTURER or LECTURER IN ORGANIC CHEMISTRY at Makerere University College, Uganda—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 28).

ASSISTANT LIBRARIAN (chartered librarian preferably with some experience in a university or technical college library)—The Clerk to the Governors, Woolwich Polytechnic, London, S.E.18 (October 30).

LECTURER or ASSISTANT LECTURER (preferably specializing in algebra) IN MATHEMATICS at the University of Basutoland, Bechuanaland Protectorate and Swaziland—The Secretary, Inter-University Council for Higher Education Overseas, 33 Bedford Place, London, W.C.1 (October 30).

SENIOR LECTURER (honours graduate with postgraduate qualifications and research experience in the physiology and genetics of animal breeding) IN ANIMAL BREEDING IN THE DEPARTMENT OF VETERINARY ANIMAL HUSBANDRY, University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, October 30).

ASSISTANT LECTURER IN THE DEPARTMENT OF PSYCHOLOGY—The Registrar, University College of North Wales, Bangor, North Wales (October 31).

CHAIR OF CHEMICAL ENGINEERING at the University of Canterbury, Christchurch, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, October 31).

CHAIR OF PATHOLOGICAL BIOCHEMISTRY—The Secretary of University Court, The University, Glasgow (October 31).

LECTURER (preferably with a Ph.D. or equivalent experience in metallurgy) IN METALLURGY—The Registrar, The University, Sheffield (October 31).

PROFESSOR OF AGRICULTURAL ENGINEERING—The Registrar (Room 22, O.R.B.), The University, Reading (October 31).

BIOCHEMIST or CHEMIST (Scientific Officer grade), initially to work on the action of organo-phosphorus insecticides and causes of resistance—The Secretary, Rothamsted Experimental Station, Harpenden, Hertfordshire (November 1).

CANCER BIOLOGIST (trained in zoology, veterinary science or medicine, and preferably some experience in the maintenance of experimental tumours in mammals, in the pathology of tumours, and in animal tissue culture techniques) IN THE DEPARTMENT OF MICROBIOLOGY, University of Auckland, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 2).

ELECTRON MICROSCOPIST (with up-to-date experience in specimen preparation techniques for biological materials) to take charge of electron microscopy in the Department of Microbiology, University of Auckland, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1, New Zealand and London, November 2).

LECTURER (with special qualifications and research interest in some branch of physical geography) IN GEOGRAPHY; a LECTURER (with postgraduate qualifications and research interests in experimental psychology) IN EXPERIMENTAL PSYCHOLOGY; and a LECTURER (with qualifications in entomology, and preferably research experience in ecology) IN ZOOLOGY at the University of Auckland, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 2).

LECTURER IN PURE MATHEMATICS at the University of Waikato, Hamilton, New Zealand—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (New Zealand and London, November 3).

LECTURER, Grade II (preferably with a medical qualification) IN PHARMACOLOGY—The Registrar, The University, Bristol (November 6).

POST-DOCTORAL RESEARCH ASSISTANTS (2) (biochemists or chemists) IN THE DEPARTMENT OF BIOCHEMISTRY, to undertake research in the general

field of sulphate metabolism—Prof. K. S. Dodgson, Department of Biochemistry, University College of South Wales and Monmouthshire, St. Andrew's Place, Cardiff (November 10).

LECTURER (with an honours degree in psychology and preferably a higher degree) IN PSYCHOLOGY at the University of Queensland, Australia—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (London and Brisbane, November 13).

LECTURER IN PHYSICAL CHEMISTRY (Durban); and a LECTURER IN INORGANIC CHEMISTRY (Pietermaritzburg), University of Natal, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, November 14).

LECTURER OR JUNIOR LECTURER IN THE BIOCHEMISTRY SECTION OF THE DEPARTMENT OF BOTANY, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (South Africa and London, November 14).

ANALYTICAL CHEMIST (with experience in analytical chemistry, preferably on silicate materials) IN THE DEPARTMENT OF GEOPHYSICS, for work involving the chemical analysis of silicate materials, rocks, meteorites and minerals, both for major and trace element concentrations—The Bursar, Australian National University, Box 4, G.P.O., Canberra, Australia (November 30).

LECTURER (with a mathematical or physical background, preferably at doctoral level, and capable of teaching meteorology to postgraduates) in the field of meteorology IN THE DEPARTMENT OF GEOGRAPHY, University of Malaya—The Secretary, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, S.W.1 (Malaya and London, November 30).

ASSISTANT DIRECTOR (with an honours degree in botany, a sound knowledge of two or more modern languages, ability to write good English, and preferably some editorial experience)—The Director, Commonwealth Bureau of Plant Breeding and Genetics, School of Agriculture, Downing Street, Cambridge (January 15).

AGRONOMIST (national of the United Kingdom or the Republic of Ireland, with a degree in agriculture or horticulture and at least two years experience in the field of experimentation or two years postgraduate training) in Tanganyika, to be responsible for a programme of field experimentation, often involving many district trials off the main research centres—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.213/173/06.

ASSISTANT OR ASSOCIATE PROFESSOR IN THE DEPARTMENT OF BIOCHEMISTRY—Dr. M. Blanchaer, Department of Biochemistry, Faculty of Medicine, University of Manitoba, Winnipeg 3, Manitoba, Canada.

CHIEF TOXICOLOGIST to take charge of the Toxicology Department; EXPERIMENTAL PATHOLOGISTS (preferably with experience of animal histopathology, tissue culture or immunological techniques); RESEARCH BIOCHEMISTS (preferably with experience in metabolic studies, biochemical pharmacology, enzyme biochemistry or connective tissue biochemistry)—The Secretary, British Industrial Biological Research Association, Woodmansterne Road, Carshalton, Surrey.

ELECTRONIC ENGINEER (preferably with H.N.C. in electronic or electrical engineering) IN THE DEPARTMENT OF PHARMACOLOGY, The Medical College of St. Bartholomew's Hospital, to assist in the design and construction of electronic apparatus used for research into drug action—The Clerk to the Governors, St. Bartholomew's Hospital, London, E.C.1, quoting Ref. PT/697.

GRADUATE RESEARCH STUDENT (recently graduated engineer (honours degree or Dip. Tech.) wishing to work for an M.Sc. or Ph.D. degree) IN THE MATERIALS GROUP of the Department of Civil and Mechanical Engineering to investigate the creep and high temperature properties of metals—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

PASTURE RESEARCH OFFICER (national of the United Kingdom or the Republic of Ireland, with an honours degree in natural science, agriculture or agricultural botany and at least two years postgraduate work in pasture research) in Tanganyika, to study the means whereby annual production can be increased through improvement in pastures and the consideration of how tropical grasslands can be managed in the context of local agriculture systems to give the maximum economic production without deterioration—The Appointments Officer, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.213/173/04/6.

PLANT PATHOLOGISTS (nationals of the United Kingdom or the Republic of Ireland, with a degree in botany or natural science, and preferably specialist training or postgraduate experience in mycology, virology or plant pathology) in Northern Rhodesia, to investigate major diseases of crops of economic importance and to make recommendations based on experimental results—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.213/132/07.

RESEARCH FELLOW (with a Ph.D. degree and preferably electrochemical or organic chemical experience) IN THE DEPARTMENT OF CHEMISTRY, for work in either of the fields of molten salt electrochemistry or the chemistry of coal components—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1.

RESEARCH STUDENT IN GEOGRAPHY—The Registrar, The University, Hull.

SOILS AGRONOMIST (national of the United Kingdom or the Republic of Ireland, with an honours degree in agriculture or horticulture with agricultural chemistry as the main subject, and preferably postgraduate experience in the field, experimental work concerning soil fertility and a knowledge of tropical soils and crops) in Sarawak, to design and conduct field experiments with a variety of tropical crops on selected soil types in order to assess the potentiality of the soils—The Appointments Officer, Room 301, Department of Technical Co-operation, Eland House, Stag Place, London, S.W.1, quoting Ref. RC.213/155/02.

TECHNICIAN (aged 30–40, with experience of routine chemical pathology, and preferably F.I.M.L.T. or equivalent), to take charge of routine laboratory services and to supervise junior staff in the Mineral Metabolism Unit—The Director, Medical Research Council, Mineral Metabolism Research Unit, The General Infirmary, Great George Street, Leeds.

U.S. PUBLIC HEALTH SERVICE: NATIONAL INSTITUTES OF HEALTH

STATEMENT

THE National Institutes of Health, U.S. Public Health Service, have recently announced that 14·7 million dollars in biomedical research project grants were awarded to institutions in 57 countries outside the United States during the financial year ending June 30, 1964. The regional distribution of awards was as follows (dollars):

Europe	5·5 million
Latin America	2·0 „
Canada	2·0 „
Middle East	1·3 „
Asia	1·3 „
Australia and New Zealand	0·7 „
Africa	0·4 „
International organizations	1·5 „

During the present financial year, ending June 30, 1965, the funds from the National Institutes of Health available to institutions and scientists outside the United States will total 13·5 million dollars—a reduction of 8 per cent from the previous year's total.

It is anticipated by the Institutes that this reduction in funds, which is dictated by the unfavourable United States balance of payments abroad, will be limited to economically advanced countries. Such countries, which include those of Western Europe, Canada, Australia and New Zealand, may, as a group, anticipate a reduction of approximately 15 per cent in total National Institutes of Health funds available during the present year. The allocation to these countries, which will amount to a total of 7·0 million dollars, will be sufficient to meet all existing commitments but will necessitate a reduction in new grants and in renewal of previously supported projects of approximately 13 per cent during the present year. Approximately 2·2 million dollars will be provided for new and renewal awards.

The funds available to less economically and scientifically advanced countries will be maintained at approximately the same level as in the previous year. A total of 6·5 million dollars will be allocated to such countries (including international organizations), of which 2·4 million dollars will take the form of new and renewal grants.

The National Institutes of Health have stated that they will continue their policy of making awards on a competitive basis, using scientific excellence, uniqueness and programme interests as criteria for approval of applications submitted. Fixed ceilings in individual countries are not contemplated.

Continued support of biomedical research throughout the world is considered by the National Institutes of Health to be an indispensable complement to research by scientists in the United States. Projects supported in other countries represent a very careful selection from among the many opportunities offered to solve specific biological and medical problems of interest to both the United States and foreign investigators by using research skills, materials and resources not found in the United States.

National Institutes of Health fellowship and training programmes, collaborative research projects between American and foreign scientists, and projects supported with American-held local currency abroad, are expected to continue at present levels or to increase.

AMERICAN AID FOR SCIENTIFIC AND MEDICAL RESEARCH

THE grants which the National Institutes of Health of the United States Public Health Service have been making for biomedical research projects outside the United States have been made in the belief that such support is an indispensable complement to research carried out by scientists in the United States. These overseas projects supported from the United States represent a very careful selection from among opportunities offered by the utilization of research skills, materials and reserves not found in the United States to solve specific biological and medical problems of interest to investigators both in the United States and elsewhere. That the unfavourable United States balance of payments abroad has dictated a reduction of some 8 per cent in the funds which the National Institutes of Health are able to make available during the year ending June 30, 1965, compared with the previous year, for institutions and scientists outside the United States does not, however, affect the belief of the Institutes in continued support of such overseas research. It is in fact anticipated that the Institutes' fellowship and training programmes, collaborative research projects with foreign scientists, and projects supported with American-held local currency abroad will continue at their present levels or increase.

If this is the first point that should be noted, the next is to thank the National Institutes of Health of the United States Public Health Service for the very considerable financial and other assistance they have given to scientific research in the medical and related fields all over the world. That, as the Statement itself indicates, such assistance brings at least indirect returns to the donor, because scientific advance is international and indivisible, in no way detracts from the generosity of the United States in giving such aid, to which, moreover, no strings have been attached. The opportunity of paying just tribute to the generosity of the people and Federal Government of the United States is as welcome as the appreciation of scientists in Britain is deep and sincere.

With that word of thanks should go also one of equal appreciation that, when compelled to reduce to some extent the magnitude of this assistance, the United States has so wisely chosen to limit the reduction to the economically advanced countries. The funds available to the countries less advanced economically and scientifically will be maintained at approximately their present level, and of the total of 6·5 million dollars, 2·4 million will be available in the form of new or renewed grants. Even in the economically advanced countries the alloca-

tion will suffice to meet all existing commitments, although involving a reduction of some 13 per cent in new grants and renewal of support for existing projects.

There is thus nothing of the start-and-stop principle about the change in policy, and the unavoidable reduction has been placed where it is most fair and just. A much severer cut should undoubtedly be accepted by the advanced countries before aid to those less advanced is restricted, even when full regard is had to the way in which the benefits of research in the advanced countries flow into those less advanced. There can be no doubt that the United States Public Health Service is fully justified in its action, and that the decision is sound and wise from the scientific point of view.

It should be remembered, moreover, that the aid provided to Great Britain by the United States Public Health Service is only a part of that received from the United States. During the past forty years the Rockefeller Foundation has provided the Medical Research Council with funds for about 200 Rockefeller travelling fellowships for advanced research abroad, and until recent years these were almost the only such appointments available. There are now many other opportunities for highly qualified young investigators, and the Foundation made its final contribution of 25,000 dollars to this programme in 1963. Besides this, however, the Rockefeller Foundation has made other generous grants for research in biophysics and in biochemistry for work at the Universities of Cambridge, London and elsewhere.

The importance of these fields for medical research can scarcely be overstressed any more than the implications for medicine or molecular biology. In the present context it is sufficient to remember that the finance and the organization of medical research are most appropriately considered in relation to the finance and organization of scientific research generally. First, however, it is to be noted that the National Institutes statement does not indicate what proportion of the 5·5 million dollars awarded by the United States Public Health Service to institutions and scientists in Western Europe in 1963–64 went to Great Britain. Even with a high proportion of this total, the 15 per cent reduction for 1964–65 can scarcely be of the order of £100,000, especially as in a survey of the finance of medical research published earlier this year (*Nature*, 203, 999; 1964) the Office of Health Economics did not consider it significant enough in amount to distinguish, although emphasizing that in the United States the Federal Government in 1965 contributed some 205 million dollars to medical research mainly through the National Institutes of Health.

Government expenditure on medical research in Great Britain in 1961–62 is estimated at £14·5 million and in 1962–63 at £15·5 million, and clearly if it were simply a matter of finance, it would be reasonable to expect that the Government should promptly provide a further contribution of the order of £100,000 or even of £200,000 to make good any interruption of research that the reductions now announced in aid from the United States might otherwise necessitate. This, however, is only a part of the issue. Financial support may be an important factor determining the advance of medical and allied research; but it is by no means the only factor determining the pace of medical progress. It is a permissive rather than a direct stimulus, and expansion of funds does not necessarily accelerate progress, which may, for example, be limited by the intractable nature of particular problems, which depend for elucidation or solution on advance in other and possibly unexpected fields.

It is also clear from the Statement that the National Institutes of Health, in making their grants, have sought to do so on the same principles as have guided the Rockefeller Foundation in its choice of projects and individuals for support—scientific excellence, uniqueness and promise of growth. This is the policy which guides also the Carnegie Institution of Washington and the Nuffield Foundation and is increasingly accepted as marking the most appropriate field of work for the independent Foundation. The Office of Health Economics in the survey just mentioned also noted a marked tendency among the charitable trusts and organizations to provide their support for medical research not only along general lines, but also in terms of the investigation of specific diseases.

To the extent, therefore, that the aid given by the National Institutes of Health has been along either of these lines, the replacement of the cut by Government grant is not quite so simple. In the first place, the Foundations have frequently selected for support projects which, from their very nature, while of high promise, were unlikely to attract Government support. The appropriateness, if not the desirability, of continuing such projects, or embarking on new projects of like character, with direct Government grant, is at least open to question. Even if the Treasury agreed to release its control over further considerable sums of public money, the whole trend of recent reports from the Select Committee on Estimates suggests that that Committee is at present far too obsessed with asserting the principle of close accountability to Parliament to appreciate what is involved in the control of speculative research projects. Furthermore, the Medical Research Council has repeatedly expressed the view that in Britain no worth-while projects in medical research are held up by the absence of funds.

In this position, on the financial side the Government would probably do better to offset the reduction in American aid by an increase in the grant to the University Grants Committee. University expenditure on medical research through the University Grants Committee is estimated at something more than £8 million a year, or about the same order as the expenditure by the Medical Research Council. Neither the universities nor the University Grants Committee could well refuse or even question an earmarked grant of a further £200,000 or even £500,000 for medical research in the circumstances: the larger grant would be a more dignified compliment to the United States.

That, however, is only the first step. Finance is only a part of the problem and one that is often misunderstood in the discussions on medical or on pharmaceutical research which, whether in Parliament or elsewhere, have been more often bedevilled by sectional or political, even party political, prejudice than informed by sense and sound judgment. With it should go a fresh appraisal of both the structure and objectives of medical research in relation to scientific research generally, and this should be undertaken by the Minister of Education and Science before and not after the reorganization of civil science at present contemplated is finally enacted. Nor, so far as objectives are concerned, is it a matter for that Ministry alone. At least the Minister of Health is involved, for one of the questions which was raised in *The Finance of Medical Research* is whether the balance of public advantage lies in stimulating medical research or in seeking short-term

economies in expenditure on the National Health Service. There is some evidence that Britain has gone too far in the latter direction, with dangers to the national economy as well as to scientific research that have yet to become apparent. Grateful as all should be to the United States for the generous help she has long given—and is continuing to give—Britain and other countries in the support of medical research, countries outside the United States have reason to be even more grateful if the present slight reduction leads us to think more realistically and imaginatively alike about the objectives of medical research and its finance and organization in the context of public accountability and public benefit.

NUCLEAR OPTICAL MODEL

The Optical Model of Elastic Scattering

By P. E. Hodgson. Pp. viii+211. (Oxford: Clarendon Press; London: Oxford University Press, 1963.) 30*s*. net.

DURING the past ten years or so, the use of the nuclear optical model of elastic scattering has been attended by a steady improvement in the description of experiments throughout wide regions. This model represents the nucleus as a spherically symmetric potential well in which absorption of the bombarding particle can occur, and some of the improvement has come about because theoreticians have indicated logical modifications to the simple form of potential which was first conceived. Account must also be taken of the mass of experimental data accumulated during this period, and a third reason for the success of the model is that the use of computers by analysts, such as Dr. Hodgson, has greatly helped the phenomenological approach of variation of the parameters of the potential. Because most experimentalists now have ready access to computers, it is to their advantage to know how to analyse their own results, and for that reason alone the appearance of *The Optical Model of Elastic Scattering* is justified. In addition, the book provides a description of the model and its history up to the middle of 1962 which it is convenient to have in the same volume, both to remind and to serve as a source of reference to original papers. All newcomers to experimental nuclear physics will find rewarding reading here.

The first chapter describes the introduction of the model (1949–52) to account for the observation of nuclear transparency and very broad resonances (in neutron total cross-sections) which appeared, at the time, to be inexplicable by the compound nucleus model. The more important limitations of the model are explained and the inclusion of a spin-orbit term in the potential is discussed. The student surprised by the sudden introduction of the rotation parameter β on p. 21 will find it defined 20 pages later. He should also note that in equation 1.17 (taken from Schiff's *Quantum Mechanics*) the function $U(r)$ has different dimensions from that used previously in, for example, equations 1.2 and 1.9.

In Chapter 2, the treatment of averaging over sharp resonances is reproduced giving reconciliation with the compound nucleus model and introducing the compound and elastic scattering cross-sections. In equation 2.10, a bar over the symbol for reaction cross-section has crept in unobserved. By p. 30, the author has begun to describe the fundamental process of producing cross-sections by solving the Schrodinger equation for a local optical model potential using numerical methods. At first, the simplest case of bombardment of a spinless nucleus by an uncharged spinless particle is considered. (In fact, the list of properties starting on p. 30 marks the particle as being that rare bird, the spinless neutron.) Later on, the effects of Coulomb field and spin are introduced.

The next chapter gives further extensions to the analysis, dealing separately with particles of unit spin, a non-local potential and an isotopic spin-dependent potential. The inclusion of these refinements has sound theoretical foundation and, indeed, so have two others noted, the spin–spin addition to the potential and the representation of a deformed target nucleus by a spheroidal well. There is experimental evidence, however, that spin–spin forces are small, and difficulties arising out of the distorted potential approach are noted. This chapter is particularly well written and covers a good deal of ground in 16 pages.

Chapter 4 is an account of the fitting process. In one sense, an optical model analysis is irreversible; that is to say, one can use potentials to derive an angular distribution but not vice versa, so fitting involves variation of the parameters of the potential. When a good fit is obtained, the possibility remains that other parameters might give an equally good fit. (The necessity for the variational procedure accounts for the great value of a computer.) The author gives approximate values to start the process and some rules on what variations should be made to achieve the desired result, followed by ways of minimizing the deviations. The chapter ends with a discussion on the uniqueness of the parameters obtained, that is, whether or not they are physically realistic.

The fifth chapter is very properly by far the longest, being concerned with the scattering of nucleons, a diverse subject in which the validity of the model is least questioned. In the discussion of size resonances, both here and in the introduction, it is not emphasized that this property of a potential well was realized long before the optical model, probably because readers are expected to be well grounded on a book such as that by Schiff. The peaks in the neutron strength function and their interpretation by Feshbach, Porter and Weisskopf in terms of the model are described, also the difficulties introduced by the compound elastic scattering when few exit channels are open. This is followed by a discussion of the energy dependence of the depth of local potentials for neutrons. and attempts to account for it by a non-local potential (which depends not only on the neutron position (r) but also on the wave function in the neighbourhood of r). Such a potential is readily shown to be momentum-dependent. Similar considerations are then paid to proton scattering. There is a section on fluctuations of the parameters of the potential as a function of N, Z, and energy, the presence of which was expected and can now be established, and finally a section on the importance of the potential shape, in particular the absorptive part.

The two succeeding chapters deal with the scattering of composite particles (deuterons, helium ions and heavy ions), and mesons, for which the characteristic features are different from those of the nucleon situation, the experimental data are sparser and the model is less well-tried. A return to nucleon scattering is made in Chapter 8 but for high energy collisions. An account is given of the formalism needed because of relativistic effects, and because the short de Broglie wave-length implies better localization of the nucleon but makes high angular momenta important. There is a mistake in equation 8.33, where "imaginary part" should read "real part", as reference to equation 8.28 makes clear.

The ninth chapter concerns itself with the bound state problem and not with elastic scattering at all. The subject is introduced here because at negative energies the optical model goes over into the single particle model for bound states. It is felt that a short account of the Lane, Thomas and Wigner intermediate coupling model would have been valuable for several reasons. The connexions of the optical model with the shell model and the compound nucleus model are emphasized, particularly by the appearance in the formula for the size resonance of the single particle width and the absorptive potential W. Experimentalists might well find this kind of discussion involving other familiar models more to their taste than the account of Brueckner theory in the last chapter. It must be

granted, however, that this is clearly reviewed and is the most fundamental way we would expect to be able to understand the optical model.

Dr. Hodgson's book is a well-balanced presentation, it satisfies a need and is coherent. Proof reading has been generally thorough, notwithstanding the two different spellings of the name Mottelson which were noticed and the incorrect reference date for Wolfenstein (1956 should be 1954) on p. 161. I would make one criticism concerning the symbol k which is used throughout the book both for momentum and wave number. In Appendix C, headed "Numerical Relations", k, said to represent the wave number, is defined as a quantity with the dimensions of momentum. On p. 161 k is used for momentum, but in equation 5.16 it is the wave number again, this time having the correct dimensions. Also in Appendix C the units of E are not stated.

Paper, printing and binding of this book are all of the excellent standard one has come to expect from the publisher and the price is very reasonable.

J. E. Evans

THE 'FORE AND AFT' OF SEDIMENTARY ROCKS

Paleocurrents and Basin Analysis

By Prof. Paul Edwin Potter and Prof. F. J. Pettijohn. Pp. viii + 269 + 30 plates. (Berlin: Springer-Verlag, 1963.) 40 D.M.

In any rapidly advancing subject a valuable contribution can be made by a timely review of existing knowledge. Profs. Potter and Pettijohn have attempted such a survey of one aspect of sedimentology, namely, the usefulness of directional properties in determining current patterns and analysing sedimentary basins.

There are ten chapters. The first outlines the use of palæocurrent investigation, shows how this is related to other aspects of geology, and itemizes the directional properties concerned. A historical review of palæocurrent investigations follows. Chapters 3–8 deal with the directional properties themselves. Arrangement of fabric elements and the geophysical properties resulting from preferred arrangements are examined first. Cross-bedding, ripple marks, other linear structures and deformation structures follow in sequence. Chapter 7 relates internal directional structures to the geometry of the sedimentary bodies containing them. Dispersal patterns and the current systems they reveal are discussed. Chapter 9 covers the more theoretical aspects of basin analysis. The model concept of sedimentary basins is developed and illustrated with examples. A final chapter reviews methods of investigation, including the collection, processing and statistical analysis of data, and presentation of results.

In layout the book is thus sound and logical, and a vast amount of useful information is assembled. The authors' main thesis and their views on integrating various lines of investigation are worth while and sometimes illuminating. Unhappily, however, the book as a whole is disappointing, mainly due to weaknesses in choice and presentation of material. There are many signs of hasty preparation, the standard sometimes falling short of that expected in a scientific treatise.

The most obvious weakness was perhaps self-imposed. In their preface the authors state that "much of what has been written about the environmental significance of sedimentary structures is omitted; that which pertains to their relation to transport direction and to basin analysis is emphasized". Obviously, over-concentration on environments would have detracted from the main topic. But the treatment of environments and the origin of structures is too slender and lacking in rigour. This allows, even encourages, a rule-of-thumb approach. A more exhaustive examination of origins in place of the repetitive and irrelevant parts of the text would make the book twice as useful. Irrelevancies certainly exist. For example, in the section on deformation structures, features having no known or inferred directional significance are described at length. Sometimes the text reads like a manual of sedimentary structures—not a review of a limited topic.

Balance between detail and generalization is uneven. Sometimes there is too much detail: sometimes relatively uncritical generalizations obscure unsolved problems. Surprisingly little reference is made to hydraulics and only a few Recent examples are taken.

Any review must rely heavily on published work. Here, too much of it is presented uncritically and some important references are omitted. In contrast, unpublished theses are referred to—a growing habit these days.

Ease of reading is impaired by the style ('catalogue English') and the profusion of bibliographic references in the text. This is exasperating because, being a reasoned whole, the book should read from cover to cover. Increase in the number of page cross-references and improvement of subheading and paragraph styles would help.

Occasional textual mistakes, such as spelling, can be excused where the intention is obvious. But misspelt names cause confusion (for example, Forgottson and Fergotson for Forgotson) or misunderstanding (for example, Nairn is always rendered as Narin). At least 9 spellings in the text differ from those in the reference list. More serious errors concern publication dates. No fewer than 18 dates in the text disagree with the bibliography. Generally the discrepancy is a few years, but ranges up to a century. At least 8 references in the text do not appear in the bibliography. Such carelessness inevitably casts doubt on the accuracy of the volume and page numbers listed. Blame is not always attributable to the printers. For example, (1) "Old Red Sandstone" appears where "New Red Sandstone" is intended, and (2) a reference to the work of Donner and West in a large area of south-eastern England leads the reader to a publication by Donner and West on a small area in Spitsbergen!

The statistical section in the last chapter is weak. Too much prior knowledge is assumed. Those able to understand will find most of this unnecessary. Obvious slips feature in 3 formulæ. More surprising is the calculation of an arithmetic average where 3 out of 9 numbers are wrong.

Text figures, generally clear and informative, are plentiful. Some are beautifully drawn, but many described as "modified from" previously published illustrations lack indication of the nature or extent of the modification. Some of the inconsistencies could have arisen from this. For example, a map showing cross-bedding directions is accompanied by a rose diagram which gives their frequency distribution but contains a northerly component not on the map. Many of the legends need amplification. Figures and textual statements about them do not always tally.

The plates are good, generally illustrating the points discussed. A few of them, however, lack scales. The method used for indicating current directions is occasionally ambiguous. Currents are variously described as "parallel to top of page", "from lower right to upper left", etc. Confusion inevitably arises when the photographs are mounted sideways on the page. Arrows marked on the pictures would have avoided this.

Intended for "both the student new to the subject and for the experienced geologist whose work leads him to the study of sedimentary basins", the book falls short of the mark. Students new to the subject will find it heavy going and must be warned of the imperfections. Experienced geologists able to detect and avoid such pitfalls will value the compilation while lamenting its deficiencies.

CYANINE CHEMISTRY

The Cyanine Dyes and Related Compounds

By Frances M. Hamer. (The Chemistry of Heterocyclic Compounds: a Series of Monographs.) Pp. xxxvi+790. (New York and London: Interscience Publishers, a Division of John Wiley and Sons, 1964.) 340*s*.

THE ability of certain dyes to make silver halide emulsions sensitive to light of wave-lengths longer than those to which they respond *per se* has made possible the more faithful photographic reproduction of scenes in black and white. Also, without sensitizers colour photography would have been unknown and all film speeds would have been severely limited since no energy derived from light of the longer wave-lengths could have been utilized. Noisy arc lamps in the film studio would certainly have handicapped the production of sound films —sensitizers made possible the change to the yellower but silent filament lamps. Thus photography in many of its technical aspects has been intimately connected, for the past 60 years, with sensitizers, and the useful sensitizers have almost invariably been selected from a class of dyes known generically as the cyanines. Dr. Frances M. Hamer brings out these points in the interesting introduction to her volume in the Interscience series of monographs on heterocyclic compounds. She has been associated perhaps more than anyone else with the chemistry of the cyanines and it is therefore most appropriate that this monograph should be written by her.

With some important exceptions, notably in the merocyanine series, characteristically, cyanine molecules comprise two heterocyclic nuclei, very often quinoline or benzothiazole, one of which bears a quaternized nitrogen atom, joined by an odd number of carbon atoms in such a way that the two nitrogen atoms of the heterocyclic residues are linked in a fully conjugated system. This volume is devoted almost entirely to the synthetic aspects of the subject. Dr. Hamer has collected together an enormous mass of information, culled mostly from the patent literature, and has classified it according to the type of cyanine and the basis of the methods of preparation.

Nomenclature in the cyanine field has often been confusing in the past, and the systematic names of the various classes can be rather cumbersome. Dr. Hamer has chosen to use semi-trivial names in the text but systematic names in the chapter titles. Thus the chapter devoted to "pentamethincyanines" includes sections on "2,2′-dicarbocyanines", and "thia-2′-dicarbocyanines". One can sympathize with the author in her dilemma and congratulate her on her solution.

The sheer bulk of material discussed has obviously made it impossible to include enough structural formulæ to make the text easily readable. For the most part only the structures of reaction products are given and it will be necessary for the reader himself to translate the names of intermediates and starting materials into structures. His task is not made easier by the labelling of formulæ with the cumbersome Roman numerals or by cross-referencing to chapters and sections of chapters rather than to particular pages.

Dr. Hamer has obviously been handicapped by the particular nature of her subject which, being closely connected with technology, is subject to trade secrecy. Thus the constitutions of particular sensitizers in present-day use are not disclosed. The patent literature, of great importance in this field, is of little value in the assessment of the relative values of different products.

The sources of information also make it difficult to select the best method of preparation of a compound, although whenever possible the yield of product has been given.

This book will be invaluable to chemists about to work in the field of cyanine chemistry and will for many years be a standard work of reference. As with other monumental compilations, by the time it finally appeared in print the work recorded was already a few years old.

A. F. CROWTHER

PLANT CHEMISTRY

The Chemistry of Plant Processes

By Prof. C. P. Whittingham. (Methuen's Monographs on Biological Subjects.) Pp. 209. (London: Methuen and Co., Ltd., 1964.) 25*s*.

IN the words of Prof. C. P. Whittingham "this book attempts to present concisely a broad survey of plant physiology and biochemistry suitable for university students . . . who should have some basic knowledge of the physical sciences". There is little doubt that it succeeds admirably in these aims.

The first part, occupying slightly more than half the book, deals with cellular metabolism. Starting with a brief statement of the historical development and the nature of experimental botany, Prof. Whittingham then sets the modern scene with an outline of the fine structure of plant cells and the methods of studying organelles and their functions. This leads naturally to a chapter on enzymes as an introduction to the metabolic meat of the book, the four chapters on fermentation and respiration, energetics of respiration and biological syntheses, photosynthesis and nitrogen metabolism respectively. Together these four chapters make up nearly half the book and are masterpieces of conciseness and clarity. Prof. Whittingham has been absolutely ruthless in the elimination of all unnecessary frills and verbiage, and the result is a highly condensed and, at the same time, completely thorough and readable portrayal of the present-day scene. The reader is brought right up to date on recent advances although there is no neglect of the classical foundations that have made these advances possible.

The second part of the book is entitled "Plant Processes" by which is meant phenomena of plant function which are not susceptible to the same dissection into discrete chemical processes as those of the first part. The author includes the osmotic relations of the cell, the water relations of the whole plant, the transport of solutes and growth. The first of these chapters on osmotic phenomena is as excellent as those preceding it, but thence the quality declines somewhat. Possibly because the relevant phenomena cannot yet be examined with comparable precision, possibly because the systems involved are more complex and difficult to define, the author has not been able to weld the selected material into such a satisfying story. This is particularly true of the chapter on growth, which is incomplete and a little disjointed; but this might have been cured by a more generous allocation of space, since even the masterly conciseness characterizing the first part of the book could not be expected to create a balanced statement of such a complex subject as plant growth in a mere twenty pages.

The book closes with an eleven-page appendix on the chemistry of the constituents of living organisms. This could with profit have been longer.

As was his intention, the author has produced an excellent framework on which the student of plant-physiology and biochemistry can base his further reading. For this there are 167 titles in a list of references in which the inclusion of a few additional critical review articles would have been an improvement.

In spite of these minor criticisms the book excellently fills a very real need and can be strongly recommended to all advanced students of botany.

L. J. AUDUS

SOURCE-BOOK OF LABORATORY INFORMATION

Laboratory Handbook

Edited by N. L. Parr. Pp. xi+1520. (London: George Newnes Ltd., 1963.) 210*s*.

THIS is a remarkable book: within its 1520 pages of well-illustrated text, the editor and 46 other contributors have sought to provide " . . . a useful source of information for those already engaged in any given field to technique and equipment employed elsewhere which may be relevant or capable of adaptation for their particular problems".

The editor has organized the book into twelve parts and in the first very briefly reviews laboratory design, organization and administration—mainly from the public service aspect. Part 2, construction of apparatus, includes, *inter alia*, chapters on electronics, remote-handling, furnaces and a particularly useful introduction to the manipulation of glass. The third part is concerned with measurement —dimensional, optical, electrical and thermal. Part 4 deals with essential techniques such as photography, optical and electron microscopy, X-ray crystallography and vacuum technology, while Part 5 covers the more specialist requirements, for example, low temperatures, distillation, high purity, inductive and dielectric heating; radioisotopes are given a whole part (6) to themselves. Part 7 contains 238 pages and is a comprehensive survey of chemical analysis. Particularly commendable is the chapter on physical methods which furnishes excellent introductions to the principles, instrumentation and procedures of emission spectrography, polarography, flame photometry, X-ray diffraction and fluorescence techniques, electron microscopy and diffraction, radioactivation analysis and ultra-violet, visible and infra-red absorptiometry. Included are comprehensive tables of detection limits, diagnostic wave-lengths and half-wave potentials in a variety of base electrolytes. On the other hand, it is to be regretted that the editor was unable to include sections on such important aids to the analyst as mass spectrometry (dismissed in two lines in Part 5) and atomic absorption; instruments for both techniques are now commercially available. More understandable perhaps is omission from a book of this type of reference to specialist tools of the organic chemist, such as nuclear magnetic resonance, electron spin resonance and optical rotatory dispersion equipment.

Part 8 is equally valuable: five chapters (186 pages) cover mechanical testing, non-destructive testing, industrial radiography, metal corrosion and soil tests. Part 9 is concerned with the work and equipment of specialized laboratories: eighteen widely divergent fields are discussed (from forensic to pharmaceutical, rubber to refractory) and yet the editor apologizes for omissions (for example, forestry and building). Laboratory hazards, including fire, toxicity and radiation, are succinctly reviewed in Part 10, while three chapters in Part 11 briefly consider the recording, analysis and presentation of results. Here the 'non-specialist' is more likely to be deterred by the condensed account, if he is not already familiar with the 'simple statistical procedures' given: this is unfortunate since a wider appreciation of the value of analyses of variance and tests of significance is desirable—not to mention standardization of nomenclature. Finally, Part 12 indicates various information services and methods of publication. The general index contains less than 2,000 entries: in a book of this size and scope this might be considered barely adequate.

In a necessarily superficial work, it is not difficult to make minor criticisms within a given field. Thus there is a lack of correlation between references in various sections to electronic devices: the brief descriptions of primitive valve and transistor circuits in Chapters 3 and 6 serve only to whet the appetite. Only the non-chemist would find useful the summary tables of gravimetric and volumetric procedures in Chapter 32. No distinction is made between a.c. and d.c. polarography, although appropriate instruments are named. Frequent mention is made of 'colour temperature', but no cross-reference is given to the short explanation in Chapter 13—and no mention at all in the index. The scientific application of ciné photography is briefly dismissed and the availability in Britain of magnetic stripe for 8-mm sound films is not mentioned. A few inevitable typographical errors have escaped notice, but they are mainly self-evident.

Notwithstanding these and similar criticisms, this handbook surely achieves the editor's primary aim. While the price will generally preclude purchase by the individual, this work should not be buried in the laboratory central library; copies should be made available on a divisional basis for general browsing by staff at all levels.

G. F. Phillips

STRUCTURE AND FUNCTION OF THE LIVER

The Liver

Morphology, Biochemistry, Physiology. Edited by Ch. Rouiller. Vol. 1: Pp. xiii+683; 26 dollars. Vol. 2: Pp. xiv+674; 171*s*. 6*d*. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.)

THIS book in two volumes attempts to correlate hepatic structure, function and biochemistry. Particular emphasis is laid on the subcellular and molecular levels as revealed by electron microscopy, histochemistry, cytochemistry and by isotopic methods. Many authors are concerned, all active workers in their respective fields, mainly derived from Switzerland and the United States with a few representatives from Britain, Canada, France, Germany and Hungary.

The editor, Ch. Rouiller, is an eminent electron microscopist, and this technique is particularly well covered, both in his two very comprehensive chapters and in those of others. Guido Majoro contributes a thought-provoking chapter on liver cell death, and Stanley Hartroft an outstanding account of experimental cirrhosis. K. Alterman uses electron microscopy to describe sinusoids and sinusoidal cells. Hans Elias (p. 44) provides a valuable diagram of the ultrastructure of the liver cells, and A. M. Rappaport (p. 176), in another diagram, attempts to correlate the ultrastructure with the cellular metabolism.

The cyto- and histo-chemistry of the liver are discussed by M. Wachstein. The isolation, morphology and biochemistry of the cell components of the liver are described by Yvonne Moulé and Jean Chauveau. These authors advise caution in the interpretation of the results, for the cell fractions are not in the state they find themselves *in situ* and a mean value is obtained without reference to extremes in the population. Nevertheless, such methods do allow investigation of functional interrelationships within the cell. The importance of nuclear cytoplasmic interrelationships in respect of DNA and RNA is emphasized.

A. M. Du Bois writes a fascinating account of the human embryonic liver. He touches on normal anatomy and physiology, regretting that more is not known of bile secretion in the embryo. The section on abnormalities is rather brief and will be of little help to the clinician anxious to know more of a particular defect in any individual patient.

H. Elias emphasizes the continuous nature of the hepatic parenchyma. Lobules are imaginary areas which can be created arbitrarily around portal canals or hepatic vein roots. A. M. Rappaport prefers to group the liver anatomically into acinar units arranged around an axis of terminal hepatic arterioles, portal venules and bile

ductules, lymph vessels and nerves which grow out together from a small triangular portal field. A concentric zonal relationship is established between these acinar cells and their blood supply. A most interesting interpretation of classical histopathology can be made in terms of the acinar concept.

A. Fischer contributes a comprehensive account of the dynamics of the liver circulation. He raises the question of the purpose of the large portal venous flow in relation to hepatic requirements. He suggests that the large portal circulation is not primarily concerned with the needs of the liver, but that the liver merely acts as a thoroughfare for blood from the splanchnic area.

Hepatic metabolism is covered fairly fully. Amino-acids and proteins are described by H. Tarver, lipids by P. Farager, carbohydrates by L. A. Pesch and Y. J. Topper, biliary excretion by Burton Combes, steroid metabolism by C. B. Cameron, vitamins by A. Wiss and F. Weber, and liver and blood coagulation by C. A. Bouvier and P. A. Maurice. The chapter on liver function tests by G. Milhaud is interesting but patchy. Tests, such as formal gel, sia and cadmium, are included which are quite out of vogue to-day and which have been replaced by more specific indications of hepatic function. On the other hand, the chapter includes a fascinating account of how human liver biopsy material may be incubated in various media so that defects in hepatic metabolism may be understood. This represents an important, advancing field.

Cancer of the liver in man is discussed by H. Elias and its relation to experimental dietary liver disease by E. B. Taft. Unfortunately, no mention is made of the place of contamination of foodstuffs by moulds which can produce the carcinogen, aflotoxin. This important subject will have to wait for the second edition.

These volumes are well produced and profusely illustrated. They provide a comprehensive source of literature. The references include titles of papers and number some 1,200—about one-fifth of the two volumes. The author index is careful and complete. The chief criticism lies in the lack of correlation between one chapter and the next, which is the common fault of the multi-author book. The chapters are of a variable length which does not always depend on the importance of the subject in relation to the whole work. Liver sinusoids, for example, are covered in 76 pages, whereas the basic anatomy of the liver occupies only 19. The practice of numbering the figures chapter by chapter instead of serially throughout the book enhances the isolation of one section from the next. The postulates of one author are often ignored or denied by the next. The volumes must therefore be regarded as a series of monographs rather than as a complete coverage of the subject. A good basic knowledge of the liver is demanded of the reader.

The volumes provide a stimulating, up-to-date account of the morphology, biochemistry and physiology of the liver. They deserve a wide success and should be found in every medical library. SHEILA SHERLOCK

BLOOD ENZYMES

Enzymes in Blood Plasma

By Benno Hess. Translated from the German by Keith S. Henley. Pp. xii+167. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1963.) 64*s*.

THE recent progress in the use of enzyme assays for clinical diagnosis has been reflected in some excellent text-books which deal with the theory of enzyme action and the techniques used in the clinical laboratory. *Enzymes in Blood Plasma*, by Benno Hess, does not concern itself with details of the tests as they are used at the bench, and refers in each case to the relevant original literature. There is a section on methods which describes the general principles of measurement of enzyme activity, reaction velocities, the role of temperature and the advantages of substrate excess.

The main parts of the book are devoted to the biochemistry of enzymes and to their "pathology and clinic". The title of the book does not prevent Prof. Hess from discussing enzymes in urine, cerebrospinal fluid, and fæces. One table lists, with full references for further reading, 47 plasma enzymes. Five are named plasma-specific because they appear regularly in the plasma at a higher level of activity than in the tissues from which they are derived: cæruloplasmin, pseudocholinesterase, the lipase for lipoprotein, and the enzymes which convert, respectively, plasminogen into plasmin, and prothrombin into thrombin. The other 42 are the excretory enzymes such as the phosphatases, and the numerous cellular enzymes, representing virtually all levels of intra-cellular activity.

There is a discussion on the identification of enzymes. This may be done, for example, by determining their primary, secondary, tertiary or even quaternary structure, or by investigating function, be it activity, kinetics, thermodynamics, or biological parameters such as genetic determination and immunological properties. The clinical section discusses the diagnostic value of enzyme estimation for a growing list of diseases of different organs. They include: heart, liver, pancreas, muscle, blood, kidney, bones and the nervous system. Special applications are described for diseases of children and for gynæcological problems. One is surprised to find in a work with such emphasis on theory so many sound rules of thumb and practical guidance for the clinician.

Though the author has attempted to be selective with his quotations of literature, there are 587 references in a book with 141 pages of text. Inevitably there cannot be much detailed discussion and evaluation. Nevertheless, this is a stimulating monograph which brings a new approach to a rapidly expanding section of clinical biochemistry. H. LEHMANN

PATHS OF INFLUENCE IN MEDICAL THOUGHT

The Growth of Medical Thought

By Lester S. King. Pp. xi+254. (Chicago and London: University of Chicago Press, 1963.) 5.50 dollars; 41*s*.

THERE are many ways of writing medical history. For example, the approach may be chronological or biographical, that is, illustrative by the lives of pioneers like Harvey, Simpson, Lister, Ehrlich and Fleming who have advanced knowledge and therapy by their work and discoveries.

The method of approach selected by Dr. King is that of the concepts and ideas that have influenced medicine. In the course of this investigation he also makes use of the chronological and biographical methods, although, as he explains, his particular selection of eras and authors is purely arbitrary. Above all, he urges his readers to remember, first, that these scientists of the past were of equal intelligence to those of to-day, and, secondly, that their doctrines and explanations, however erroneous, must be evaluated in the light of knowledge then available.

The book begins with the religous aspect, instancing the epidemic among the Greek forces besieging Troy which was ascribed to the arrows of Apollo in the *Iliad*. A similar explanation was given to outbreaks of pestilence among the Anglo-Saxons as due to elf-shots, arrows from malignant elves. Indeed the belief that diseases generally are a punishment for sin is held by many up to the present day.

From Homer onwards, through Asclepios, the doctrines of Hippocrates and his School represent the scientific medicine which co-existed for a long time with the religious and magical beliefs of the Greeks. Here there was thoughtful observation and deliberate reflexion. It is not very important, says Dr. King, that much of it was wrong by to-day's standards. The association with stagnant water in marshes and lakes was good observation, although it was not realized that they were the breeding places of the mosquito *Anopheles*. The concept of the four humours—the blood, phlegm, yellow bile and black bile—which endured for many centuries was partly observation, but mainly based on mistaken inference.

Galen is the next exemplar, and he is now recognized as a keen observer and experimentalist. Many of his theories and inferences were wrong, but his voluminous writings advanced and consolidated medical knowledge. Because his work and doctrines were regarded as truths for all time well into the sixteenth century, he should not be blamed for this lack of progress.

For the philosophical approach, Dr. King describes the work of Paracelsus at some length. Yet Paracelsus had little influence on medical thought in his own time and for long afterwards. It is only of recent years—and especially through Pagel's recent investigations—that the work of this physician-philosopher towards medical progress has come to light, for the mists of magic, alchemy and astrology long obscured it. As to Vesalius, Dr. King praises the *De Fabrica* as a work of genius, but observes, as Prof. C. D. O'Malley has shown in his recent biography of the great anatomist, that others had previously developed anatomical investigations and paved the way for his insight and initiative.

In considering William Harvey's work, Dr. King deals solely with the discovery of the circulation of the blood. This has overshadowed Harvey's other original work as a public health administrator and adviser to the State, a pioneer in embryology and neurology, a forerunner of Wallace and Darwin, the founder of scientific midwifery, a planner of the first pharmacopœia, an epidemiologist, an advocate of smoke abatement, one who first showed that contagious and infective disease spread through the blood, and whose prophetic vision extended even to the threshold of bacteriology.

Friedrich Hoffman and his theories are discussed at some length. The last chapter, entitled "The Cell Theory: Key to Modern Medicine", is of special interest, for Dr. King is a pathologist. Introduced by an account of the great Boerhaave, the exemplars here are Schwann, Rokitansky and Virchow. The epilogue to this scholarly book ends with the view that the medical doctrines of to-day will be the discarded theories of to-morrow. This, of course, is true to a large extent, but, as this book reveals, despite much confusion and error throughout the history of medicine, the path of advance to fuller knowledge is unmistakable. ARTHUR MACNALTY

RATIONAL VIROLOGY

Viruses of Vertebrates

By Sir Christopher Andrewes. Pp. xi+401. (London: Baillière, Tindall and Cox, 1964.) 63*s*. net.

BEFORE the Second World War, when the isolation and identification of viruses were still part of the search for the causes of disease, there was no need to give them any names apart from those of the conditions for which they seemed responsible. So accounts of the viruses became books about virus diseases first, and catalogues of related viruses second; the parasites themselves were lumped together as bacterial, plant, or animal viruses according to which department of the kingdom of living organisms they happened to infect, rather than as the expression of any relationship between the viruses assigned to each group. The great expansion of virus research during and after the War, in particular the revolution brought about by the introduction of tissue-culture techniques to virology, has now made such a classification neither convenient nor necessary. Many viruses exist the clinical manifestations of which, if any, are unknown, and many syndromes are known to be the work of more than one virus. So the time is ripe for an attempt to classify viruses on the basis of more fundamental properties than their ability to cause disease. No one could be more fitted to make this attempt than Sir Christopher Andrewes, who has been actively investigating viruses throughout this formative period during which virology has progressed from being a special corner of bacteriology to become a science in its own right which can perhaps shed light on the roots of the whole of biology. So it is not surprising that he has produced a book that will be as important to the virologist as Bergey's *Manual* to the bacteriologist, or Bentham and Hooker to the amateur of wild flowers.

Sir Christopher groups viruses into broad divisions, based mainly on physical and chemical properties. These include the possession of a cubical or helical symmetry of protein sub-units, and whether or not there is an outer envelope enclosing this more rigid structure. This last-mentioned seems to be correlated with a chemical attribute, namely, sensitivity to destruction by ether, bile salts and certain detergents. Another chemical criterion, the possession of a single type of nucleic acid, serves to divide viruses into two main groups containing either DNA or RNA, and also to exclude the psittacosis–lymphogranuloma–trachoma group, which contains both. Pathological properties are considered only in so far as they are necessary to identify a virus, or indicate its economic importance. When applied to viruses infecting vertebrates such criteria reveal the existence of broad groups with a wide similarity in structure, behaviour and habitat. Among them are the myxo- and picorna-viruses, the homogeneity of which invites guesses about a possible underlying unity in the chemistry of the cells they infect; cells may only possess a limited set of tools for processing their environment, and there may be only a few ways in which viruses can be constructed to exploit them.

To generate speculation is, of course, one of the virtues of any scheme that is more than a successful key to the identification of species. Good classifications express patterns the significance of which may not be suspected at the time they are devised. Thus the Linnean system contained the seed of the evolutionary tree, and the Periodic Table of the elements exposes underlying structural patterns among the atoms which comprise it. By these standards, Sir Christopher Andrewes's classification is an exciting one, and it would be petty to carp about details like his acceptance of dubious criteria—such as the results of acridine orange staining—to determine the nucleic acid type of a virus. Where better evidence is not available, we must accept the data we have. This book also shows admirable caution in refusing to assign to a group any virus about which there is doubt, and in admitting that some of the groups may still be artificial collections of unrelated agents. One can only praise the author's refusal to foist on us a binomial system of virus nomenclature such as Holmes and Zhdanov have suggested. But one wishes at times that Sir Christopher would throw caution to the winds. One can see the necessity of restricting the length of this book, but it is a pity that, while attempting a rational classification, he should restrict himself to viruses of vertebrates. This is only a slightly narrower pigeonhole than the old 'animal viruses' and has the same fault of grouping viruses by their hosts. A bold system of classification, like that proposed by Lwoff, Tournier and Plissier, seems at first to bring together seemingly unrelated viruses infecting plant and animal cells, but may actually reveal an unsuspected

truth—that there are indeed only a few ways in which viruses can be constructed. One hopes that Sir Christopher, in his next book, will attempt a broad survey of all macromolecular 'particles' with infective properties. It might show up some interesting resemblances between, say, certain insect viruses and arbo- or plant-viruses able to multiply in their insect vectors. In the meantime, *Viruses of Vertebrates* deserves a place on the bookshelf of every virus laboratory. F. K. SANDERS

BREEDING BETTER RICE

Genetics and Breeding of Rice

By Prof. M. F. Chandraratna. (Tropical Science Series.) Pp. ix+389+12 plates. (London: Longmans, Green and Co., Ltd., 1964.) 70*s*.

RICE is the staple food of more than half the World's population. It so happens that many of the people who depend on it inhabit the newly developing countries and in these parts of the World diets are often inadequate. Compared with other important staple cereals the scope for crop improvement through rice breeding is large, particularly within the tropical *indica* sub-species where the range of variation in morphological and physiological characters is very wide. The *indica* group has been much less thoroughly worked by plant breeders using modern methods than most other important staple cereals, and the large-scale exploitation of the variation derived from *indica* × *japonica* crosses has only recently begun. There is little doubt that big increases in rice production can be made with little capital expenditure by breeding and distributing improved seed.

Apart from any academic interest, therefore, the publication of a new book on rice breeding is an event of potential economic and humanitarian importance. Prof. Chandraratna, in the preface to his new book, acknowledges his debt to other recent books on rice breeding, but there is little doubt that his own work represents an original and considerable advance on these. His attractive and critical approach makes the book very readable; no section is merely a catalogue of information. It is well produced with excellent line-illustrations. Unfortunately, about half the photographs are of poor quality and sometimes rather pointless; it is to be hoped that they could be replaced in a later edition. The bibliography includes papers not referred to in the text. Such a list is of doubtful value unless it is substantially complete, and this list excludes several important recent publications; it might have been better to have restricted it to text references.

The book begins with a succinct account of the origin and taxonomy of rice. This is followed by chapters on morphology, hybridization techniques, cytology and cytogenetics, sterility, and the genetics of morphological characters. Most of the remaining chapters are of immediate practical importance and they discuss the genetics of metric and physiological characters, photoperiodism, linkage groups, hereditability and interrelations of metric characters, principles and procedures of pure line and mass selection, pedigree and bulk-population methods, fertilizer response, breeding for disease resistance and cooking quality, induced-mutation breeding, and seed improvement and certification.

One of the most useful chapters in the early part of the book is a description of techniques of hybridization. This is the best illustrated account which has so far been published. One minor criticism, however, is that it is stated that poor germination is obtained after using emasculating techniques which result in seed deformity. This ignores Carpenter's recent work which shows that excellent germination is obtained with these methods if the seeds are afterwards germinated under sterile conditions.

It is now becoming obvious that photoperiod responses are extremely important in rice agronomy, and it is necessary for rice breeders to pay a great deal of attention to them. The chapter on the photoperiodic control of flowering is well written, as one would expect, since Prof. Chandraratna was the first to emphasize the quantitative nature of the response in rice and show the importance of constructing photoperiodic response curves. However, this close personal contact with the problem seems to have led to insufficient emphasis being placed on later work, particularly that of Best, whose main monograph[1] (not referred to in the bibliography) provides the clearest and most comprehensive description so far available of photoperiodism in rice. Prof. Chandraratna finds it hard to relinquish his original concept of defining response curves in terms of second-degree polynomials, in spite of the fact that Best's recent experimental curves bear little relation to this ideal. Part of the attraction of this concept was the use of an objective criterion (the rate of change of curvature of the second degree polynomial) for the assessment of photoperiod sensitivity. In this chapter the inadequacy of this criterion is quite properly pointed out (it had already been demonstrated by Best). Prof. Chandraratna now suggests that the best measure of photoperiod sensitivity is provided by the linear regression coefficient of that section of the curve which covers the range of variation of natural daylengths. But this would also seem to be a doubtful procedure, since Best's work shows that the curves in this region do not approximate to a straight line except in the case of very sensitive varieties.

The important chapter on fertilizer response includes an interesting discussion of crop yield in terms of growth-analysis concepts. The basis of this discussion is the well-known hypothesis that lower yields are normally experienced in the tropics because the higher temperatures increase respiration ($Q_{10} \approx 2$) but not photosynthesis ($Q_{10} \approx 1$); dry-matter production represents the balance between photosynthetic gain and respiratory loss. This is a neat explanation and, because it is, there is a tendency to accept it too readily as fact. Such acceptance could discourage work in a field where it is urgently required. The hypothesis may be true but it assumes rather too easily that respiration represents total loss without explaining what happens to the energy provided by it (or is it implied that it is all lost as heat?). Might not the energy be used to produce the higher growth rates which Njoku has shown to exist in other plants under tropical conditions? Thus the dry-matter loss due to respiration might be balanced by higher leaf-area indices and thus more photosynthesis. Another possible explanation to account for the differences in yield of rice in the tropics compared with the sub-tropics might be found in the intrinsic differences between the tropical *indica* varieties and the sub-tropical *japonica* varieties. As Prof. Chandraratna points out later on, there is evidence that *indica* varieties have a higher crop-growth rate than *japonicas* but that the *japonicas* convert much more of the dry-matter to grain than the *indicas*. Here, obviously, is the basis of a clearly posed research problem of immense importance. The scientific value of phytotrons in relation to their cost is questioned in some quarters, but the operators of one of the new installations could find ample justification for their facilities in the exploration of this important economic problem.

There is not space here to do full justice to Prof. Chandraratna's book, but the few controversial points raised here indicate the stimulating level at which it is written. It will be a most useful source of information and inspiration to all rice breeders—particularly to those who work under the sometimes trying conditions associated with rapidly developing agricultures.

E. H. ROBERTS

[1] Best, R. (1961). Some Aspects of Photoperiodism in Rice (*Oryza sativa* L.) (Elsevier Publishing Co., Amsterdam).

Advances in Food Research

Vol. 12. Edited by C. O. Chichester and E. M. Mrak. Pp. ix+433. (New York and London: Academic Press, 1963.) 100*s*.

IN this twelfth volume of a valuable series of reports on technological and scientific advances in knowledge of food handling the editors have collected seven contributions from experts of varied experience and nationality. In a paper on chemistry of non-enzymatic browning, T. M. Reynolds of the C.S.I.R.O. Division of Food Preservation, Australia, not only discusses the reactions at present known between aldoses and amines in concentrated and dried foods but also poses a series of important questions which call for further investigation.

Osmophilic yeasts, which cause spoilage of dried fruits, concentrated fruit juice, honey, maple syrup, curing brines and salted meats, are reviewed by Hiroshi Onishi of the Noda Institute for Scientific Research, Chiba-ken, Japan, with special attention to the characteristic tolerance of high concentrations of sugar and salt by such yeasts. It is emphasized that further work on the genetic origin of these high tolerances is needed.

Transport and storage are the subject of two papers from the United Kingdom. W. Hugh Smith, of the Agricultural Research Council Ditton Laboratory, assembles the present information on the use of carbon dioxide in the transport and storage of fruit and vegetables, and K. C. Hales, of the Shipowners Refrigerated Cargo Research Association, Cambridge, reports on designs in refrigerated shipping and on types of cargoes and their particular requirements.

A more recondite problem is set forth by J. S. Pruthi from the Central Food Technological Research Institute, Mysore, India. He discusses the physiology, chemistry and technology of passion fruit. This fruit has had a limited market owing to its relatively short storage life. The paper gives a most interesting survey of improvements in handling and in the preparation and use of passion fruit products for man and for animal feeding.

From the Technical Centre of the U.S. General Foods Corporation, Martin Glicksman contributes a most useful account of the utilization of synthetic gums in the food industry. Advances in the preparation of cellulose derivatives, polyvinyl compounds and other types of synthetic gums and resins have made this an increasingly important field of food technology, and this paper deals with nutritional and technical aspects.

The final paper, by Eiichi Tanikawa of the Laboratory of Marine Food Technology, Hokkaido University, Japan, is concerned with the fish sausage and ham industry in Japan. It is fascinating to discover how fish can be reddened and processed to form 'ham'. The handling and storage of processed fish foods is considered in detail.

There are certainly more components in food than man may dream of, and these papers help to widen the views of all who are interested in the problem.

A. M. Copping

The Production and Uses of Natural Graphite

By A. R. Tron. (Department of Scientific and Industrial Research: Warren Spring Laboratory.) Pp. viii+83. (London: H.M. Stationery Office, 1964.) 5*s*. 6*d*. net.

THE underlying theme of this instructive little book is to present a re-appraisal of the economic value and intrinsic properties of the natural mineral graphite in face of the ever-increasing tendency to use artificially produced material. The versatility of natural graphite in the arts is perhaps not generally recognized. Most of the world's production, about 70 per cent, is consumed by the metallurgical industries, in crucibles, foundry facings, moulds, retorts, pouring nozzles, refractory bricks and other similar articles. In the manufacture of lubricants, brushes for electrical machinery, batteries, pencils, stove polishes, electrodes, explosives and paints, to mention a few other applications, natural graphite plays a prominent part, while one of the most modern uses explored by the West German graphite industry is in the production of graphite blocks for nuclear purposes.

The author's argument is that this great variety of usage of natural graphite, coupled with variations in degree of purity, has tended to a lack of understanding between producers and industrial users of the mineral; this is further accentuated by the absence of any universally accepted methods for testing and classifying such desirable qualities as durability, flakiness, and particle toughness. The conclusion is drawn that in these circumstances many users are over-specifying purity of the raw graphite involved to the detriment of varying grades of the natural mineral which may be potentially satisfactory for the product concerned; in some instances these impurities would have no critical effect on performance.

That there is a serious deadlock in the industrial situation as regards production and consumption of natural graphite at the present time is abundantly clear from the author's findings. Producers want to be assured well in advance of planned exploitation of a long-term market of particular grades satisfactory to users; the latter, however, appear reluctant to adjust formulæ and manufacturing techniques to suit new graphite producers; meanwhile competition resulting from increasing use of less expensive forms and grades of artificial graphite is growing. "If it is to compete effectively with this new trend, the natural graphite industry in all parts of the world will have to be prepared to support a more extensive research effort to discover and develop new outlets for natural graphite, and to improve technological preparedness." This book is commendable for the impartial manner in which the facts are presented, and it merits the close study of producer and user of graphite alike.

British Transistor, Diode and Semiconductor Devices Data Annual, 1963–64

Edited by G. W. A. Dummer and J. Mackenzie Robertson. Pp. lxxi+1610. (London and New York: Pergamon Press, 1963.) 200*s*. net.

British Miniature Electronic Components Data Annual, 1963–64

Edited by G. W. A. Dummer and J. Mackenzie Robertson. Pp. xviii+1356. (London and New York: Pergamon Press, 1963.) 140*s*. net.

American Subminiature Electronic Component Parts Data Annual, 1963–1964

Edited by G. W. A. Dummer and J. Mackenzie Robertson. Pp. xiii+679. (London and New York: Pergamon Press, 1963.) 140*s*. net.

British Miniature and Microminiature Electronic Assemblies Data Annual, 1963–64

Edited by G. W. A. Dummer and J. Mackenzie Robertson. Pp. xii+335. (London and New York: Pergamon Press, 1963.) 105*s*. net.

THE increasing importance of electronics in technology is exemplified not only by the number of text-books and manuals dealing with the subject, but also by the number and size of the publications furnishing data on the range of transistors and other semi-conductor devices and electronic components which are available.

In the series of electronic data annuals published by the Pergamon Press, there are two new volumes: the second volume of *British Transistor, Diode and Semiconductor Devices Data Annual* and the third volume of *British Miniature Electronic Components Data Annual*. Under the same editorship, that of G. W. A. Dummer and J. Mackenzie Robertson, are also two companion volumes, *American Subminiature Electronic Component Parts Data Annual* and *British Miniature and Microminiature Electronic Assemblies Data Annual*.

These books collect, into compact individual volumes, manufacturers' data sheets and basic information on electronic components, and in addition provide, where appropriate, sections dealing with operating principles, applications and design methods. They are, in fact, compendia of electronic techniques. The annual dealing with British microminiature electronic components and assemblies is, in fact, a new book, based on the "Assemblies" section which previously formed part of the *British Miniature Electronic Components Data Annual*. The increasing use of thin-film solid-state units and of printed-circuit techniques has made it necessary to devote more space to miniature and microminiature electronic assemblies.

This series of annuals forms a source of technological data and information on electronic techniques which is remarkably comprehensive. The books are well indexed and the information therefore readily accessible. The series forms a most valuable day-to-day reference for research workers and designers concerned with electronic equipment, and should serve a most useful purpose when placed, perhaps, in the research laboratory or workshop rather than in the library. J. GREIG

Controlled-Potential Analysis

By Garry A. Rechnitz. (International Series of Monographs on Analytical Chemistry, Vol. 13.) Pp. 85. (Oxford, London, New York and Paris: Pergamon Press, 1963.) 35*s*.

AN electrolysis that is carried out with the potential of the working electrode fixed at a selected value is a controlled-potential electrolysis. When such an electrolysis is used in analysis it is controlled-potential analysis. Most commonly in analysis, the substance being analysed is determined by weighing the amount deposited at the working electrode, that is, controlled-potential electrogravimetric analysis. Less commonly, the amount is determined by measuring the quantity of electricity that passes during the electrolysis, that is, controlled-potential coulometry.

It is a pity that the author of this monograph has, throughout the book and especially in Chapter 1, "Introduction", used these terms at random. In fact, after reading the book, the reader is left wondering whether the author intended to write about controlled-potential analysis generally or about controlled-potential coulometry in particular.

Chapter 2, "Theory", deals with the elementary theory of controlled-potential coulometry and its application to analysis and kinetic investigations. Secondary reactions are also discussed. In Chapter 3, "Apparatus and Techniques", the ideal characteristics of potentiostats are listed and described, and five commercial instruments are appraised. Current integration by graphical, mechanical and electronic means, and the electrodes and electrolysis system, are discussed. In the final chapter, "Analytical Applications", some 35 elements are treated together with the alkali metals, the rare earths and the halides.

This work is intended for practising analytical chemists. Many would find it, in spite of the confusion of terms, a ready source of information on controlled-potential analysis. J. F. C. TYLER

Teaching Machines and Programming

Edited by K. Austwick. Pp. vii+201. (Oxford, London and New York: Pergamon Press, 1964.) 42*s*.

THIS book deals with a relatively new venture in the field of instruction. Programmed learning is the label now accepted for a group of techniques in which subject matter is presented to the individual in an orderly series of 'steps', with future progress made in some way dependent on past success, and in which the individual can be informed about the success with which he has tackled one step before proceeding to the next. Programme presentation can vary from the traditional live teacher to time-sharing computers, with simple pencil and paper devices and more complex electro-mechanical machines in between. Programmes may be written to cover very small parts or the whole of a syllabus.

By the beginning of 1963, when the six contributors wrote their chapters, industry, schools, services and universities on both sides of the Atlantic had accepted programmed learning as a useful medium in an era where demand for instruction had outstripped supply. The questions now raised are centred primarily on ways and means: Under what conditions, and for what kind of subject-matter, is programmed learning suitable when judged by a number of criteria? *Teaching Machines and Programming* answers some of these questions as well as giving the necessary background information. The writers have all had practical and research experience in programmed learning in Britain, and one common theme is the extent to which laboratory and real life merge in this field.

In Kay's searching introduction no stitches are dropped and no punches pulled. Annet's chapter includes valuable cost-accounting. Sime stresses the use of teaching machines as a research tool. Pask states the case for completely automated teaching. Reid's robust chapter is an enjoyable exposition of Skinner's ideas, pure and applied. The editor discusses the possible uses of automation in schools.

The decision to make the chapters self-contained produces much repetition of general concepts. Some of the plates are poor, and many give little idea of scale. The index and references are good. J. A. LEONARD

Comprehensive Biochemistry

Edited by Prof. Marcel Florkin and Prof. Elmer H. Stotz. Vol. 15: Group-Transfer Reactions. Pp. xii+246. (Amsterdam, London and New York: Elsevier Publishing Company, 1964.) 70*s*.

COMPREHENSIVE Biochemistry is one of a section of five volumes devoted to an examination of enzyme catalysis at the molecular level. The reader must not expect, therefore, to be presented with an integrated account of metabolic processes; this will presumably follow in a later section of this treatise. Six chapters describe the present state of our knowledge of those biochemical reactions in which a group is transferred from one substrate or co-enzyme to another. The transferred group may be as small as a methyl group or as large as an oligosaccharide residue. The reactions which are discussed in this volume include the transfer of formyl, hydroxymethyl and methyl groups (S. Harvey Mudd and G. L. Cantoni); reactions catalysed by transketolase and transaldolase (B. L. Horecker); transfer of acyl groups (P. Goldman and P. R. Vagelos); the transfer of glycosyl groups (L. Glaser); transaminations and decarboxylations in which vitamin B_6 is implicated (B. M. Guirard and E. E. Snell); and the transfer of phosphate groups catalysed by phosphokinases and phosphomutases (R. K. Crane, C. F. Cori and D. H. Brown).

Reading this volume and the others in this series dealing with biochemical reaction mechanisms emphasizes the dearth of our knowledge about the early stages of an enzyme-catalysed reaction. Investigations of pre-steady-state kinetics and the conformational changes induced in an enzyme by the approach of a substrate are virtually unexplored territories. Two features of *Comprehensive Biochemistry* must be commended. In contrast to some of the earlier parts of the treatise, this volume is not badly out of date; there are a few references as recent as 1963. Secondly, several of the authors have included a lot of detailed information in tabular form. This simplifies the reading for both the expert and the person who requires a background of modern enzymology. D. T. ELMORE

SCHIZOPHRENIA AS A GENETIC MORPHISM

By Sir JULIAN HUXLEY, F.R.S.

31 Pond Street, London, N.W.3

Prof. ERNST MAYR

Museum of Comparative Zoology, Harvard University

HUMPHRY OSMOND

Bureau of Research, N.J.N.P.I., Box 1,000, Princeton, New Jersey

AND

Prof. ABRAM HOFFER

Department of Psychiatry, University Hospital, Saskatoon, Saskatchewan

IT now appears clear that schizophrenia, at least in the great majority of cases, is based on a single partially dominant gene with low penetrance[1–3]. We wish to put forward the hypothesis that it involves a genetic morphism, a conclusion independently reached by two of us (J. H. and E. M.).

As is now agreed among evolutionary geneticists (for example, Mayr[4a] and Ford[4b]), all genetic characters which exist in a population at a higher frequency than can be maintained by mutation alone involve morphism[5]; the frequency of a morphic gene is the result of a balance between its selectively favourable and unfavourable properties.

(1) In schizophrenia there is abundant evidence of a strong genetic component.

(*a*) In single families, only certain children become schizophrenic.

(*b*) Monozygotic twin-pairs show a concordance rate of 76–91 per cent, dizygotic pairs only 10–17 per cent (for example, Kallmann[6,7], Shields and Slater[8]).

(*c*) An examination of schizophrenics and normal sibs of the same sex and less than 2 years' difference in age, whose mothers were not schizophrenic[9], showed that the future schizophrenics and their sibs manifested marked personality and temperament differences from an early age, and that these could not be associated with environmental influences, including psychological trauma. The future schizophrenics were more dependent and less able to deal with traumatic events: they were *schizoprone*, apparently from birth.

(*d*) The work of Böök[1,2] and Slater[3] on the morbid risk (likelihood of developing schizophrenia) in different relatives of schizophrenics indicates that the usual genetic basis for schizophrenia is a single dominant gene which we will call Sc, with about 25 per cent penetrance, that is, it only induces manifest schizophrenia in about a quarter of the cases where it is present in the genotype. Non-manifestation of the disease in the 75 per cent of Sc-carriers is due to the effect (1) of the genetic environment—minor genes affecting manifestation; (2) of the external environment—familial, social, cultural and physical.

(2) (*a*) Wherever reasonable statistics are available, the incidence of manifest schizophrenia is at least 1 per cent in all racial and ethnic types[10] and probably in all social classes (some authors maintain that there is an increase in the lower strata; but others have been unable to confirm this).

The only considerable exception is the 3 per cent incidence found by Böök[1] in an area north of the Arctic Circle in Sweden. This high figure is doubtless due partly to inbreeding in an isolated but physically dispersed population. Dr. Eliot Slater has further suggested to us that it is correlated with the nature of the environment. We would add that schizophrenics are more likely to be able to lead a normal life in a socially simple and physically harsh environment of this type, and one where they are necessarily withdrawn from much contact with their fellow human beings, and where husbands will not trouble very much about their wives' mental peculiarities, provided they are physically resistant and capable of elementary domestic skills. In addition, it may be suggested that the high incidence may be wholly or partly due to a higher penetrance (manifestation) of the Sc gene in a harsh environment: further investigations of the degree of penetrance in different types of environment would be of great interest.

(*b*) The high frequency of schizophrenia cannot be maintained by mutation alone, and is evidence of a balanced morphism. The fertility (reproductive fitness) of schizophrenics is only about 70 per cent of that found in socio-economically comparable normals[11]*. The incidence of the disease would therefore be rapidly reduced to the level where it is maintained by mutation alone, unless its selective disadvantages of lower viability and fertility were compensated by some selective advantage.

(*c*) There are two possible types of compensatory advantage:

(1) *Physiological.* Overt schizophrenics are extremely resistant to surgical and wound shock (and recover much more rapidly), to visceral perforation, to high doses of histamine (correlated with fewer mast cells in the skin), insulin, thyroxin and other physiologically active substances, to pain, to arthritis, to many allergies, and probably to many infections†[12–16]. One of us (H. O.) has seen a schizophrenic recover successfully from the most appalling burns which would have killed any normal person in hours or minutes‡. We suggest that crypto-schizophrenic Sc-carriers probably enjoy similar selective advantages, though presumably of lower magnitude.

Dr. Slater has suggested to us that in historic times resistance to mass epidemics of diseases like smallpox and

* Many morphic genes are lethal or semi-lethal when homozygous. In view of the drastic physiological effects of the Sc gene (see following) such lethality may well apply to it.

† But not to tuberculosis, where the schizophrenics' reduced ability to produce fibrous tissue reactions is a disadvantage. Further, since the incidence both of schizophrenia and of tuberculosis is positively correlated with Sheldon's ectomorphic (Kretschmer's leptosomic) type of body-build (see Harrison, Weiner, Tanner and Barnicot[17]), schizophrenics are more likely than normals to suffer from tuberculosis.

‡ Clarke[18] mentions some of these advantages of schizophrenia, and discusses the possibility of its being a genetic morphism, but without reaching a firm conclusion.

bubonic plague may have been a contributory factor. If the high frequency of the schizophrenia gene is in any considerable measure due to resistance to infectious diseases, especially of childhood, we may expect its steady decline in the more hygienic modern world.

(2) *Reproductive.* Male schizophrenics are certainly at a high reproductive disadvantage, through earlier onset, higher suicide rate[18], more frequent hospitalization, and failure to marry. Female schizophrenics, however, not infrequently marry, and seem to seek for affectional satisfaction through children: so their fertility may possibly be above average. In hæmophilia, a moderate increase (22 per cent) in female fertility is able to compensate for a high reproductive disadvantage (36 per cent) in males[20]. Nothing is known about the fertility of the cryptoschizophrenic Sc-carriers. This merits intensive investigation, as it could be of great importance for the frequency of Sc.

Presumably both the penetrance and the expressivity of the Sc gene are largely controlled by the residual gene-complex[21].

It will be of importance to be able to identify carriers of the Sc gene, as has been done with a number of other genes[22,23]. The simplest way would be by biochemical tests; but psychological tests would also be useful.

Many workers consider that the perceptual disorder characteristic of schizophrenics is due to a biochemical abnormality which affects the brain's sensory-perceptual integrative system. Much work is in progress on the subject. Symptoms closely resembling those of schizophrenia can be induced both by certain psychomimetic drugs[24], and by hypnotically induced alterations in perception[25,26].

Hoffer and Osmond[24,27] consider that the specific substance involved is adrenolutin, and claim that the urine of schizophrenics in 75 per cent of cases contains a substance giving a mauve reaction when tested by paper chromatography, while Friedhof and Van Winkle[28] claim a similar high frequency for a 'pink spot' chromatographic reaction produced by a closely related substance. If these claims are confirmed, and the methods improved, it might be possible to detect the responsible substance in the urine of non-manifest Sc-carriers.

Hoffer and Osmond (1961) have devised a battery of psychological tests which they claim are diagnostic of schizophrenia as against other psychoses, neuroses and, of course, normality (see also Lidz *et al.*[29]). If it proves possible to identify schizoprones in childhood by such tests, educational and other methods could be devised to prevent or mitigate the manifestation of the disease.

It is clear that schizophrenia constitutes not a purely medical or psychiatric but a biological problem, with opportunities for a combined attack in many fields—genetics, biochemistry, selection theory, psychology, psychiatry, public health, demography, social science, pathology, and general environmental and reproductive physiology.

In particular, we need further investigations: (1) of the selective advantage and disadvantage, both as regards survival (viability) and reproduction (fertility) of overt schizophrenics, non-manifest carriers of the Sc gene, and normals: and also better biochemical and psychological tests identifying the same types, and if possible applicable in childhood; (2) the heritable and environmental contributions to the manifestation of schizophrenia—the major gene (or genes) involved; its (or their) penetrance and expressivity, as influenced by modifiers and by environment; the possible influence of race, physical and cultural environment; and investigations of twins, sibs and other relatives: a comparison of same-sexed and opposite-sexed dizygotic twins would be especially rewarding. (3) Of the psychological and physiological effects of schizophrenia, overt and non-manifest, of psychomimetic drugs, and of induced alterations of perception.

Summary and Conclusions

(1) Schizophrenia probably depends primarily on a major dominant gene, Sc, with about 25 per cent penetrance.

(2) The overt schizophrenia-rate in all countries investigated is at least 1 per cent, much too high to be maintained by mutation alone. The Sc gene must therefore be in morphic balance, and must confer certain selective advantages to compensate for its obvious disadvantages, including a 30 per cent reduction of fertility.

(3) The physiological advantages are high resistance to surgical and wound shock, to otherwise dangerous concentrations of insulin and other hormones, histamine, etc., and to various allergies and infections. Cryptoschizophrenic Sc-carriers (and some overt female schizophrenics) may possibly have a higher than average fertility. Known or presumed Sc-carriers should be tested to ascertain whether they possess any degree of these advantages.

(4) The Sc gene appears to cause an error of metabolism, resulting in the formation of some substance interfering with the normal integration of perception.

(5) The temperamental and personality traits of future schizophrenics in most cases show, from early childhood onwards, distinct differences from those of permanently normal sibs of the same sex and similar age.

(6) Chromatographic tests are beginning to provide evidence of detectable 'mauve' and 'pink' chemical factors in the urine of a large majority of schizophrenics, and suitable psychological tests promise to differentiate schizophrenics from other psychotics, neurotics and normals.

(7) If such tests can be further improved, schizoprones and future schizophrenics might be diagnosed in childhood and appropriate educational and possibly medical measures taken to prevent or ameliorate overt manifestation.

GENETICAL RESEARCH IN AN AREA OF HIGH NATURAL RADIOACTIVITY IN SOUTH INDIA*

By Prof. H. GRÜNEBERG, F.R.S.

Medical Research Council Experimental Genetics Research Unit, University College, London

In wild populations of animals and plants, new genetic variance constantly comes into being by the process of 'spontaneous' mutation. Nearly all mutations upset the smooth working of the organism to a greater or lesser extent. They thus become the target for natural selection which sets a limit to their spread. An equilibrium is thus established between mutation and natural selection, and the genetic variance of a population is in a steady state.

Since the pioneering work of Muller in 1927, it has been known that mutations can be induced in all animals and plants by means of X-rays, and it has since been shown that other radiations like γ-rays emitted by radioactive substances or the cosmic rays from outer space have a similar effect. Generally speaking, the mutagenic effect is proportional to the dose administered. Whereas this relationship is comparatively easy to verify for medium and large doses up to a few 1,000 r. units, it becomes very difficult for small doses of radiation. However, by a heroic effort which involved the scoring of well over a million individuals, the linear relation between dose and mutation rate has been verified down to 5 r. units[1] in *Drosophila melanogaster* and down to even smaller doses in micro-organisms. A dose of 5 r. units is roughly what a human being, in a Western country, accumulates in the thirty years of his reproductive life due to natural radioactivity, cosmic radiation and the activities of the diagnostic radiologist. It is thus a dose which has to be taken seriously.

The question of genetic damage by radiation is essentially a medical problem. From the medical point of view, we are less interested in the occasional accident with a large acute dose of radiation. On the other hand, if the horrors of a thermonuclear war should ever be let loose on humanity, its genetical aftermath would probably be rather trivial by comparison with its immediate effects. The real danger which is with us now and likely to remain with us indefinitely is the exposure to small doses of radiation over long periods. This may happen as the result of contamination of our environment with radioactive substances and thus involve whole populations over many generations; similarly, large numbers of people may be exposed to increasing industrial risks in our changing atomic technology.

In the laboratory, it is comparatively simple to investigate the immediate genetic effects of large doses of radiation administered acutely. The long-term effects of small doses of radiation administered at a low dose-rate over many generations are far too complex for mathematical treatment and virtually beyond the scope of laboratory experiments, at least with mammals. What we want to know is this: If the mutation rate is increased as the result of radiation, will the genetic variance of a population be raised to a higher level? Or will natural selection be able to take care of the extra mutations so that the equilibrium stays where it normally is? For medical purposes, data on mammals are essential. Though all animals behave alike in principle, there may be great quantitative differences: for example, it is known that the mouse is many times more sensitive to the genetic effects of radiation than *Drosophila*[2]. Now the establishment of a new equilibrium is a slow process which takes a great many generations, and for the mouse it would take at the very least fifty years, and more probably a century or more.

Fortunately, Nature herself has carried out such an experiment for us. There exist a few areas in the world which have a high natural radioactivity. One of these areas is on the Malabar Coast of India, in the State of Kerala, and about 250 km south of Calicut where Vasco da Gama made his landfall in the year 1498 (Fig. 1). North of the small town of Quilon, there exists a narrow coastal strip some 14 miles long which is highly radioactive. The carrier of the radioactivity is black monazite sand. By a kind of 'panning' action, as in panning for gold, the waves of the Arabian Sea have here thrown up a mixture of heavy minerals which are ultimately derived from igneous rocks inland. One of these minerals is thorium phosphate; thorium is a radioactive element with a very long half-life ($1{\cdot}39 \times 10^{10}$ years). Monazite sand is found in varying quantities from Cape Comorin for about 200 km north. Its greatest concentration occurs in Manavalakurichi, just west of Cape Comorin, in the State of Madras, and on the strip north of Quilon in both of which places it is mined (opencast mining). The strip north of Quilon is an island which is separated from the mainland by backwaters which are brackish and which form the main avenue of communications between Trivandrum in the south and Cochin and beyond in the north. Whereas coastal navigation is interrupted during the monsoon seasons, the backwaters can carry traffic all the year round.

The scenery of the strip with the lagoon behind it is most attractive. Except for the beach, the strip is largely covered by coconut groves. Under the trees stand the huts of the natives, each in its own little compound. Many of the huts are very primitive and are constructed entirely of mats made of palm fronds: some stand directly on the sand, others have a base of laterite or of concrete. There are about 60,000 inhabitants of the strip, most of them fishermen and coconut growers, along with some workers in the monazite sand factories. The occupation of the strip is almost continuous from one end to the other.

Now, if a suitable mammal other than man lives on this strip, if it has lived there long enough for the establishment of genetic equilibrium between mutation and natural selection, and if the strip has been ecologically isolated long enough so that our animal—whatever it may be—was prevented from 'commuting' between strip and mainland, if these conditions are fulfilled, the strip north of Quilon would be a natural laboratory to answer the questions which have been posed.

In India, where there is man, there is the rat (the black rat, *Rattus rattus* L.). So a suitable mammal was at hand. The only other mammal which is present on the strip in any numbers is the mole rat or bandicoot (*Bandicota indica* Bechstein), a large rat-like animal which may weigh as much as 2 lb.; but we did not get it in numbers big enough for our purposes.

The field work was carried out by myself, two of my colleagues, Dr. R. J. Berry and Mr. R. A. Weiss, together with Mr. G. S. Bains, a young biologist attached to us by the Indian Atomic Energy Establishment Trombay. During the winter 1961–62, we collected in eight localities on the strip and eight control localities inland altogether nearly 900 rats, rather more than 50 per population. Measurements were afterwards carried out by members

* Substance of a lunch-hour lecture delivered in University College, London, on October 15 1964.

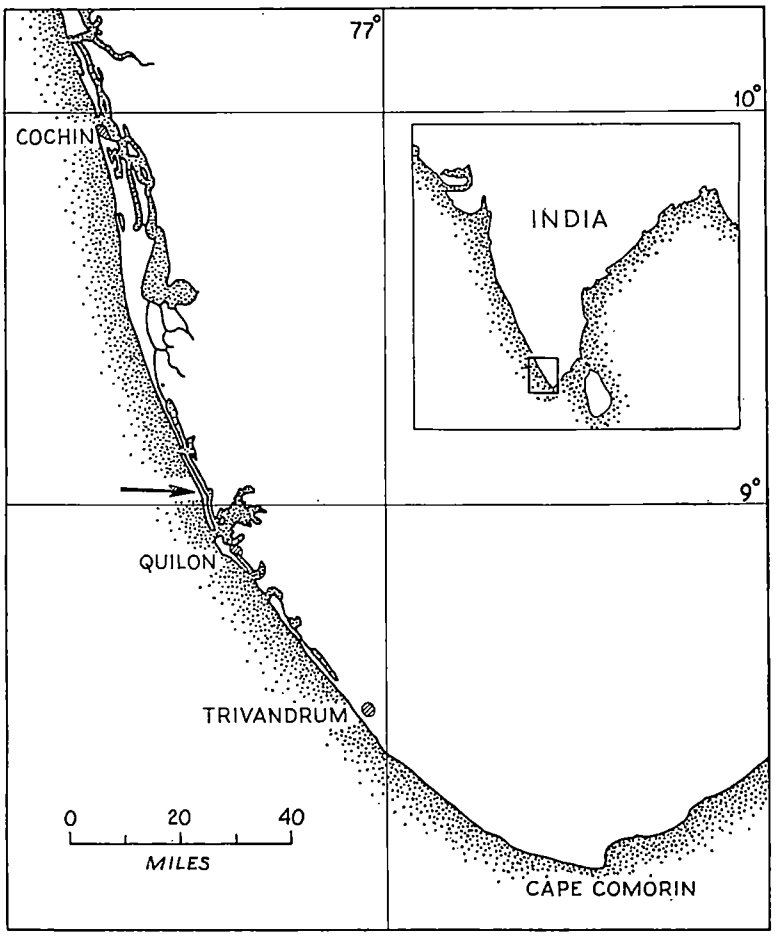

Fig. 1. Map of the Malabar Coast of India. The arrow points to the radioactive strip where the work described here was carried out

of that team, together with Mrs. Linda E. Riles. The statistical evaluation has been in charge of Prof. C. A. B. Smith. The investigation has thus been carried out by a team of six people, under the auspices of the Medical Research Council. The analysis has been completed this summer, and our report[3] has been submitted to the Medical Research Council for publication.

Returning to the question of since when the strip has been completely surrounded by water, the descriptions of the early Portuguese travellers, including Vasco da Gama himself who visited Quilon on his second journey in 1502, leave no doubt that this was so some 460 years ago. Even earlier, the great Moroccan traveller, Abū Abdullah Muhammad, commonly known as Ibn Battūta, found the same situation in 1343 when he travelled in those parts as Ambassador of the Sultan of Delhi, Muhammad bin Tughluq. Testimony to the antiquity of human settlements on this part of the Malabar Coast goes much farther back, and possibly they are already referred to by the Elder Pliny (who wrote about A.D. 75), though here the identity of the places mentioned is open to doubt. It is thus quite clear that the strip has been occupied by man, and by implication by the rat, for many centuries, and that the strip has been an island for at least 600 years or something like 800–1,000 rat generations. Clearly, our rats cannot be far from genetic equilibrium.

Next, we have to get an estimate as to how radioactive the strip really is. The distribution of the monazite sand is far from uniform. Rats can easily walk from hut to hut, and over the centuries they must have occupied the whole strip at random. As no global values for the overall radioactivity of the strip were available, the Indian Atomic Energy Establishment Trombay, at our request, carried out a very complete set of radiation measurements, with some 130 traverses from the Arabian Sea to the backwaters from one end of the strip to the other. There are two main gradients, one from the sea to the backwaters, the other from north to south. If these and local irregularities are smoothed out, the average radioactivity of the strip is about 7·5 times that of the control areas inland which were monitored at the same time. This is not as good as one could have wished. But the only area with a higher radioactivity, at Manavalakurichi near Cape Comorin, has no natural frontiers and the rats can walk to and fro as they please.

In absolute terms, individual rats on the strip, during the whole of their reproductive lives, accumulate about 1 r. unit of γ-radiation. That may seem rather a modest dose. However, the cumulative dose to which, say, 500 consecutive rat generations, in perhaps 300 years, have been exposed is of the order of 500 r. units, whereas the controls, during the same time, have accumulated a dose of only about 67 r. We set out to discover whether the chronic exposure to 7·5 times the normal amount of background radiation has any detectable genetic effects on the population.

Now one might expect that a search for genetic effects of radiation would involve breeding experiments. However, the black rat is not a laboratory animal, and in any event it is not easy to see how critical data could have been thus obtained. We therefore had to take the animals as we found them, comparing a series of 8 populations from the strip with a similar series of control populations. Selecting suitable characters known to be under genetical control, we had to find out whether there exist systematic differences between these two groups of populations. The skeleton and the teeth may be regarded as representative of the animal as a whole, and large numbers of preparations can be made rapidly by the papain digestion method worked out in this laboratory some fifteen years ago. We were very fortunate to enjoy the hospitality of the Sree Narayana College in Quilon, where a temporary laboratory was set up, complete with deep-freeze, incubator and all other equipment shipped from Great Britain.

In work of this kind, if too few measurements are taken, the material is used wastefully, but if too many are taken, there is a law of diminishing returns as biological measurements tend to be correlated with each other. One also has to take into account time and manpower available. In the end, we settled for six dental and 15 skeletal measurements; if the outcome had been ambiguous, we could always have made additional measurements on our skeletons. In addition, there was a group of some 26 minor variations of the skeleton which are mainly of the all-or-none kind such as whether or not a certain foramen in the skull is double rather than single, or whether there are fusions between cervical vertebræ; such variants are counted rather than measured, and their incidence may differ from population to population. Finally, the pregnant females which we trapped provided data on the number of living embryos, the number of dead implantations and the number of corpora lutea in the ovaries; from these can be calculated the rate of embryonic mortality before and after implantation in the uterus.

Now, given this kind of material, what would one be looking for to discover genetic effects of radiation, if any? Metrical variables are usually approximately normally distributed around a mean value which is characteristic for a given population. Populations may differ both in their means and in their variances, that is, the degree of scatter around the mean. If the genetic variance is increased as the result of a higher mutation rate, one may expect to find a higher proportion of individuals with more extreme deviations from the mean value, and correspondingly fewer near the middle of the distribution. In the case of the non-metrical minor skeletal variations, populations may differ as regards the incidence of any particular character; but if the data on all these variants are combined, a measure for the total divergence between any two populations, or groups of populations, can be obtained. On the other hand, we did not expect to find major skeletal abnormalities; these are much too rare to be found in samples of manageable size and in any event such animals tend to die before reaching adult life. None was in fact encountered.

The full results will be found in the report submitted to the Medical Research Council. Here we give a brief summary of the main findings, which is easy as all the results tell essentially the same story.

In the case of the dental measurements, there are significant differences between populations both on the strip and in the controls. Whereas the means may differ, the variances are essentially the same in all the populations. Genetical differences between rat populations from five grain shops in Delhi[4] had previously been discovered, and it was thus not surprising that similar differences between populations should also be found in Kerala. The reason for these differences is probably mainly if not entirely genetic drift (Sewall Wright effect) in the form of the 'founder effect'; that is, individual populations often trace back to small numbers of founder animals whose gene frequencies are the more subject to accidents of sampling the smaller their number. The important point is that although there are differences between populations both on the strip and among the controls, there is no sign whatever of systematic differences between these two groups of populations.

Much the same situation is found for the skeletal measurements. Again, there is a good deal of heterogeneity between the means of populations; but no sign that the two groups of populations differ systematically from each other. In this case, there is also some evidence of heterogeneity of variances though this is much less than that between means. However, there is no consistent pattern in these differences. For example, for one measurement, there is an increased variance in the control ♀♀ which is opposite to expectation. In another case, the increased variance occurs in one sex but not in the other, and in the third instance the effect on the sexes is in opposite directions. Clearly, then, neither as regards the means nor as regards the variances do strip and control populations differ systematically from each other.

Much the same situation emerges from the analysis of the minor skeletal variants. Again, there are highly significant differences between populations, both on the strip and in the controls, but no sign of systematic differences between the two groups of populations.

Finally, there are the data on fertility and embryonic mortality. Once again, there are differences between populations, but the overall fertility and embryonic mortality is just about the same in both groups of populations.

Naturally, there is the possibility that a systematic difference between strip and control rats as regards the characters investigated does, in fact, exist, but that we have failed to discover it as the result of accidents of sampling. If our results in the least pointed in that direction, one might think that larger samples are required to prove the point. But in the complete absence of even straws in the wind, it looks as if our negative results should be accepted at their face value. If so, we now have to discuss how that is to be interpreted.

The rats on the strip are exposed to the extremely low dose-rate of 0·18 mr./h. The lowest dose-rate which has been investigated experimentally (in the mouse[5]), and which is known to produce mutations, is 60 mr./h (= 1 mr./min) and thus some 300 times as high. It is at least conceivable that γ-rays, at the extremely low dose-rate to which the rats on the strip are exposed, do not produce mutations. In view of what is known about the mutagenic mechanism of ionizing radiations, this is not a probable assumption.

If, then, we assume that mutations have, in fact, been induced in the rats on the strip, our negative findings can be interpreted in two different ways which are not mutually exclusive. We may conclude that the production of mutations has been accurately counterbalanced by natural selection so that the level of genetic variance (as inferred from the phenotypic variance) has remained constant. Though our data on fertility and embryonic mortality do not, in themselves, suggest the operation of selective processes, they certainly do not exclude the low level of selection required to achieve equilibrium.

Alternatively, we may assume that the genetic variance has, in fact, increased on account of the radiation, but that this increase has been accurately counterbalanced by a decrease of the non-genetic variance, the total (phenotypic) variance remaining constant. It is a well-known fact that in inbred strains of animals from which the genetic variance has been virtually completely eliminated by inbreeding, the phenotypic variance for metrical characters is sometimes as big, or nearly as big, as in genetically mixed strains in which an appreciable part of the phenotypic variance is genetic in origin. Evidently, as the genetic variance is reduced, the environmental variance increases so that the total phenotypic variance changes little or not at all; in fact, it may increase. Whether, in a genetically mixed population like that of the rats on the strip, an accurate replacement of environmental by genotypic variance is possible such that the phenotypic variance remains constant is a question which is easier asked than answered. If *Rattus rattus* were a laboratory animal amenable to experimentation, the level of genetic variance in strip and control rats could be assessed by their response to selection. This being impracticable, it may be doubted whether with the means at our disposal a decision between these two hypotheses can be obtained. They are, in any event, not mutually exclusive.
